It is used, also for the lapping of the end, of the joint, &c. upon a trimmer, or girder; and then the thickness of the shoulder is cut into the trimmer, also, bevelled upwards, that it may just receive the gain; and so the joint and trimmer lie even and level with the surface. This way of working is used in floor and beams.

To **GAIN** the wind, in *Sea Language*, is to arrive on the weather-side, or to windward of some other vessel in fight, when both are plying to windward, or falling as near the wind as possible.

GAINAGE, **GAINAGIUM**, in our *Antient Writers, signifies the draught-oxen, horses, wain, plough, and furniture, for carrying on the work of tillage by the labor of serfs and villains.*

Gainage is the name with which the otherwise called *wainage*, *Brachon*, lib. i. cap. 9. speaking of lords and servants, says, *Et si est dominus, quod scilicet non possit eis esse wainagium suum*. And again, lib. iii. tract. 2. cap. 1. *Villanus non mercaturus, nisi forte wainagio suo*. For, particularly, as it appears both by Mag. Chart. and other books, the villain, when amerced, had his *gainage*, or *wainage*, free; to the end his plough might not stand still; and the law, for the same reason, does still allow a like privilege to the husbandman, that is, his draught-horses are not, in many cases, distrainable.

GAINAGE is also used for the land itself, or the profit raised by cultivating it.

GAIOPHLEGMA, in *Natural History*, a genus of the first order of *STEARIA*, divided by partitions of earthy matter.

GALACHIDES, or **GARATIDES**, in *Natural History*, the name of a stone to which the writers of the middle ages have attributed many ridiculous virtues. They have left us no further description of it, than that it was of a blackish colour.

GALACTITES, in *Natural History*, a stone, thus called, because when broken, or ground with water, it yields a white liquor, like milk, which the Greeks call *yaxa*. This substance much resembles the morochina, or French chalk, in many respects, but differs from it in colour. The ancients found it in the Nile, and some other rivers in Greece, and used it in medicine as an astringent, and for defusions and ulcers of the eyes. It has been supposed to increase the milk of nurses, and hang on the necks of children to promote dentition. At present it is common in Germany, Italy, and some parts of France, and is wholly overlooked, being esteemed only a worse kind of the *morochina*.

It is a very hard and dry substance, an indurated clay, of a close compact texture, very heavy, and in colour of a pale

a pale grey, without the least admixture of any other tinge. It is of a soft even surface than the morachubus, and is less hard. It melts but slowly in the mouth, and leaves something of a luscious sweetness on the tongue. It does not adhere to the lips or tongue, and if rubbed down on a marble with water, it dissolves into a substance of a pure white, resembling milk. It does not ferment with acids, and in burning becomes of a pure white. Hill's *Hist. of Foss.* p. 23.

GALACTOIDES, *Taxodioides*, of *Yaka*, milk, and *lutea* form, milk, a word used by the ancients in two or three different senses. Some used it to express tepid, or a little warm, with such a heat as that of milk just drawn from the cow; others expressed by it a white, somewhat opaque, or milky-colour; others expressed by it only a want of transparency in fluids. Galen frequently uses it in the second of these senses, when treating of urines.

GALACTOPHAGI, and **GALACTOPHYTES**, in *Antiquity*, persons who lived wholly on milk, without corn, or the use of any other food.

The words are compounded of *yaka*, *yakodis*, milk; *phago*, to eat; and *phytes* of *way*, I drink.

Certain nations in Syria and Africa, as the Getae, Nomades, &c. are famous, in ancient history, in quality of *galactophagi*, milk-eaters. Homer makes their elogia, *Iliad*, lib. iii.

Ptolemy, in his Geography, places the *galactophagi* between the Rhiphaei mountains on one side, and the Mæotic Sea on the other.

GALACTOPHOROUS *lactis*, are such vessels as serve to convey milk.

GALACTOPOTE. See **GALACTOPHAGI**.

GALACTOPSIA, a method of curing diseases by drinking milk only. The pox, consumption, and many other chronic diseases, are by many affirmed to be curable by this means. See Cheyne's Nat. Meth. of curing Diseases.

GALACTOSPONDA, *Taxodioides*, of *Yaka*, milk, and *sponda*, *lotionis*, in *Antiquity*, a LIGATION made with milk.

GALACTOSIS, of *Yakastasis*, to be converted into milk, the production of milk; or the action whereby the food, or chyle, is converted into milk.

GALADES, in *Natural History*, an epithet given by floridists to a species of *CHAMA*, remarkable for its milky whiteness. It is derived from the Greek *yaka*, milk. This *CHAMA* is a very elegant shell.

GALANGAL, **GALANGA**, a medicinal root, brought from the East Indies; the produce of a plant of the same name.

In character these are the same. It hath a single spathe of one leaf; the flower has one petal with a slender tube, divided in six parts, three of them alternately oval and spear-shaped, the other oval, and at bottom cut into two parts, which are vertically heart-shaped; and it hath one filament which is membranaceous; it has a round perigon, supporting a style the length of the tube; which afterwards becomes a roundish three-cornered capsule with three cells filled with seeds. We have but one species of this plant in England, known by botanical writers under the title of *Kampferia*, and is a genus of the *menispermia* class.

There are two kinds of *galangal*, the *small* and the *great*. The *smaller* is by far the most in esteem, and is almost the only one heard of in prescription. The *galanga minor*, or lesser *galangal*, is a small thort root, of an irregular figure, of the thickness of a man's little finger and is seldom met with in pieces of more than an inch or two long. It has several protuberances at its ends, and on its surface, and is surrounded with many circular rings, that stand out a little beyond the rest of the surface. It is of an extremely firm and compact texture, yet not heavy; it cuts difficultly with a knife, and leaves a polished surface. Its colour is a brownish-red on the outside, and fuscous brighter-red within, though still with a considerable admixture of brown.

The small *galangal* are to be chosen full and plump, and of a bright colour, very firm and sound, and of an acid and insupportable hot taste.

They were formerly in common use as warm stomachic bitters, and generally made an ingredient in bitter infusions; but they are now almost wholly laid aside, on account of their unpleasant flavour. Bitterness does not appear to be the proper medical character of this root; the heat and pungency greatly prevailing. A very fiery extract is made from it with rectified spirit, and the watery extract is also very hot and pungent; in distillation with water, it yields an essential oil, about a grain in quantity from sixteen ounces of little smell, and no great pungency: so that the pungent matter of the *galangal* appears to be of the same nature with that of pepper residing not in the volatile oil but in a more fixed matter. Lewis, *Mat. Med.*

The larger *galangal* grows chiefly in Java and Malabar, and answers pretty much to the above description, only that it is larger in bulk, less unequal and tuberculous, weaker, and more disagreeable than the lesser kind.

The *galangal* are both brought us from the East Indies, and are the roots of the same plant, which is of the number of the *herba halimifolia* of Mr. Ray. Heron calls that which produces the larger, *hancula Indurans*, and that which produces the lesser, *lagundi Indurans*. The people of the East Indies use these roots by way of spice.

GALANGALE, *Englibis*, in *Botany*. See **CYPERUS**.
GALANT. See **GALLANT**.

GALANTHUS, in *Botany*. See **SNOW-DROP**.

GALARCIDES, or **GALARICTIS**, in *Natural History*, a name used by the *Writers of the Middle Ages*, for a stone, to which they attribute great virtues. It is evidently only a corrupt way of spelling the word **GALACTITE**.

GALATEA, in *Metaphysics*, a sea nymph, the daughter of Nereus and Doris, thus called on account of the fairness and beauty of her complexion. See **NEREUS** and **NEPTUNE**.

GALATIANS, *Epistle to the*. See **EPISTLE**.

GALAX, in *Botany, a genus of the *pentstemonia* class: the characters of which are, that the calyx consists of a ten-leaved perianthium, the corolla of a single bowl-shaped petal, and the fruit is a single-celled, double-valved, elastic capsule. There is only one species. Linnaeus.*

GALAXIUS, in *Natural History*, a name by which many of the ancients have called the **MOROECHTICUS**, or French chalk.

GALAXY, in *Astronomy*, that long, white, luminous track, which seems to encompass the heavens like a swath, scarf, or girdle; and which is easily perceivable in a clear night, especially when the moon does not appear. The Greeks call it *Yakadas*, *galaxy*; of *yaka*, *yakastasis*, milk; on account of its colour, and appearance. The Latins, for the same reason, call it *via lactea*; and we, the *milk-way*.

It passes between Sagittary and Gemini, and divides the sphere into two parts. It is unequally broad, and in some parts is single, in others double.

The ancient poets, and even philosophers, speak of the *galaxy* as the road, or way, by which the heroes went to heaven.

Aristotle makes it a kind of meteor, formed of a crowd of vapours, drawn into that part by certain large stars disposed in the region of the heavens answering hetro.

Others, supposing that the *galaxy* was seen all over the globe, that it always corresponded to the same fixed stars, and that it transcended the height of the highest planets, set aside Aristotle's opinion, and placed the *galaxy* in the firmament, or region of the fixed stars; and concluded it to be nothing but an assemblage or an infinite number of minute stars.

Since the invention of the telescope, this opinion has been abundantly confirmed. By directing a good telescope to any part of the milky way, where, before, we only saw a confused whiteness, we now discern an innumerable multitude of little stars. These stars are so remote, that a naked eye confounds them: the like we observe in other spots, called *nebulae fixarum*; which, when examined with the telescope, are distinctly perceived to be clusters of little stars, too faint to affect the eye singly. See **STAR**.

M. le Monnier not being able to discover more stars in this space than in the other parts of the heavens disputes the opinion above recited as to the reason of the whiteness, and supposes that this and the nebulous stars are occasioned by the same kind of matter. *Iust. Art.* p. 60. See **MILKY WAY**.

GALBANETUM, a composition, or preparation, of galbanum formerly prescribed, but now much out of use.

GALBANUM, in *Pharmacy*, a gum issuing from an incision in the root of a feruleous plant, called, in Latin, *ferula galbanifera*, growing in Arabia, Syria, &c. See **BITUMEN**.

The word is derived, according to Martinus, from the Hebrew *chilmah*, fat.

There are two kinds of *galbanum*: the one in grains, or tears; the other in a coarse mass. The first is to be chosen of a golden yellow without spots, but much paler within; of a bitter taste, and strong disagreeable smell: for the second, take that which is fullest of tears, very dry, clear, and not stinking. This last is easily sophisticated with broken beans, resin, and gum ammoniac, which it resembles in its medical virtue as well as sensible qualities, being less efficacious in asthma and disorders, and more so on account of its stronger flavour, in hyssic cases. It forms with water, by titration, a milky liquor, but does not perfectly dissolve in water, vinegar,

vinegar or wine. Rectified spirit takes up more than either of these constituents, but not the whole: the tincture is of a bright golden colour. A mixture of two parts of rectified spirit and one of water dissolves all but the impurities, which are considerable. The best way of purifying it is to include it in a bladder, and keep it in boiling water, till it becomes soft enough to be strained, by pressure, through a hempen cloth: its essential oil will be thus preserved, which is carried off in evaporation both by water and spirit. The essential oil of *galbanum*, distilled with water, rises to the surface, of a yellowish colour, and in quantity about the twentieth part of its weight. The empyreumatic oil is of a blue colour, and changes in the air into purple. Lewis and Neumann.

Galbanum is of an emollient and resolutive nature, good in all hysterical cases, and in asthma, and inveterate coughs: it promotes the menses, and brings on delivery; but it is chiefly used externally, in plasters for the belly, which it also loosens, in what was never applied.

GALBULA, in *Ornithology*, the name of a bird of the thrush kind, common in Italy and Germany, very remarkable for the elegant structure and hanging of its nest; and thence called by some *passer niam suspensorius*, and by others *vinus, chlorus, and idurus*, being supposed to be the scelerus, or junco-bird of Pliny, and the old writers. This bird is somewhat larger than the common thrush: its beak is a finger's breadth long, and red; its wing-feathers are black, but some are tipped, and others edged with white; others are varied with yellow, and the rest are an extremely bright and beautiful yellow. The female is less beautiful, the yellow being more shaded with black and brown. The *galula* feeds on insects, and is in most places very much esteemed at the table, but is no where to be had at all seasons, being a bird of passage.

GALE, in *Botany*. See *Sweet Willow*.

GALE, a *Sea Gale*, for the blowing of the wind.

When the sea is not blown to hard, but that a ship can carry her top-sails a trip, that is, hoisted up to the highest, they say it is a *lean gale*.

When it blows very strong they say it is a *stiff gale*, or, at least a *fresh gale*; but when it blows so hard and violently, that a ship cannot bear any sail, they say it blows a *storm*.

When two ships are near one another at sea, and there being but little wind blowing, one feels more of it than another, they say the ship *gales* a way from the other.

GALEA, or **GALEURA**, among the Romans, was a light casque for the head, generally made of the skin of some wild beast, in order to appear the more terrible. Thus Virgil,

— *scutoque lupi de pelle galera.*

The *galea* was also a head-piece, coming down to the shoulders, commonly of brass, and sometimes of iron; the lower part was called *buccula*, and on the top was the crest.

GALEA, in *Natural History*, the name of a genus of the *conchiformia*, or sea-birds, whole shape is that of a large elevated helmet, composed of several transversely-joined plates, or scales, and covered with very small and rough tubercles, in the shape of little granules. This genus, when fossil, is called in English the helmet-stone, and is marked with ten rows of double lines, either creased, or punctured, and running from the top to the base; the anterior ones being much longer than the rest.

Of this genus there are three known species, viz. 1. The scuted headed one, which has on its summit an oblong pentagonal plate like a shield. 2. The naked headed one without this shield. 3. That with the tunic laured, and shewing that they have been once of the variculated kind. Klein's *Echinod.*

GALEA Piscis, in *Ichthyology*, a name given by Gesner, and some other writers, to the fish called by other writers *mafilea alia*, and by Arted reduced to the genus of the *blenni*. It is the *blennius*, with four hind beards under the throat.

GALEA Fovearum, in *Zoology*, a name given by some authors to the common *MUSTELA*.

GALEANTHROPIA, of *galea, cat, and anthrope*, may, in the writings of the *Antient Physicians*, a term used to express a species of madness, in which the patient fancied himself a cat, and endeavoured to perform all the motions of that animal.

GALEARI, in *Aquiculture*, *helmet-sharps*, a name the Romans gave to the black guards or servants of the soldiers. See *Negatives* iii. 6. and Salmassius on the third chapter of the life of Adrian by Spartian.

GALLEASSE. See **GALLEY**.

GALLEATE flowers. See **FLOWERS**.

GALLEETTO, in *Ichthyology*, the name of a fish of the alauds

kind, called by Rondestius, *alauda nan willula*, and in English the *magpie* and the *bullfinch*. It is a small fish of a greenish yellow, or olive colour without any variegation in some, but in others a number of faint blue transverse lines are disposed on the back, the sides, and the fins; the intermediate spaces between these lines on the back are of a reddish brown, and in some two olive-coloured and brownish lines run longitudinally down the back. The colours, in short, vary extremely in this fish. It is very full of life, and lives, like the cel, many hours without water. It is caught among rocks and stones about the shores in the Mediterranean, and also in our own seas. Willoughby's *Hist. Pile*, p. 103. Arted. reduces this fish to the genus of the *blenni*, and distinguishes it by the name of the *blennius* having the upper jaw longer than the under, and the top of the head acuminate.

GALEGA, in *Botany*. See *GOAT'S RUE*.

GALENA, a name given by *Alexander*, to a species of poor lead-ore. It was also the original name given by Andromachus to the theriaca, from its effect in bringing on a pleasing calm over the blood and spirits on taking it.

GALENA inessis, in *Minerally*, a name given by authors to a glittering substance, very much resembling some of the placed ores of lead, but really containing none of that metal. It is more usually called *mock-lead*, and blende or *blende*.

GALENIA, in *Botany*, a genus of the *stardis dignia* class: its characters are these. The flower hath no petals, but eight hairy stamina, of the length of the empalement. In the centre is situated a roundish germen; and the empalement afterwards becomes a roundish capsule with two cells, containing two oblong angular seeds. We know but one species of this genus, which grows naturally at the Cape of Good Hope. Miller.

GALENIC, or **GALENICAL**, *medicine*, is that manner of considering and treating diseases, founded on the principles of Galen, or introduced by Galen.

Claud. Galen was of Pergamus in Asia, the son of Niccon, a famous geometrician, and architect; and was a pupil of Satyrus and Pelops, two able physicians. He was born under the emperor *Adrian*, in the year of Christ 121, and first distinguished himself at Athens, then at Alexandria, and lastly at Rome; where he wrote a great deal, and where he also died.

He is said to have composed two hundred treatises, whereas there are one hundred and seventy still extant. There have been twenty-three several editions of this author. The first is that of Venice, in folio, in the year 1525, but the best is that of Paris, in thirteen volumes in folio, Greek and Latin, published in 1639.

This author collecting and digesting what the physicians before him had done, and explaining every thing according to the strictest doctrine of the Peripatetics, set physic on a new footing: he introduced the doctrine of the four elements; the cardinal qualities, and their degrees; and the four humours, or temperaments.

GALENIC is more frequently used, as contradicting itself from *chemical*.

In this sense, *Galenical medicine*, and *Galenical pharmacy*, are those which proceed upon the easier preparations of herbs, roots, &c. by infusion, decoction, &c. and attain their ends, and make their remedies effectual, by the combining and multiplying of ingredients: in opposition to the chemical medicine, or pharmacy: which torture the materia medica by fire, and draw their more intimate and remote virtues by elaborate preparations, as calcination, digestion, fermentation, &c.

Medicine was wholly *Galenical* till the time of Paracelsus. Geber, indeed, and after him Raymond Lully, Arnoldus de Villa Nova, and Basil Valentine, made some attempts to apply chemistry to medicine; especially the last of them; but no great advance was made. Paracelsus, and after him Van Helmont, altered the whole body of medicine; exploded *Galenism*, and the Peripatetic doctrine, and rendered medicine almost wholly chemical.

The late improvements in philosophy have reformed and retrieved the *Galenical* medicine, which, however, has now little of Galen's in it. It is become all mechanically and corpuscular; instead of qualities and degrees, every thing is now reduced to mechanical affections; to the figures, bulk, gravities, &c. of the component particles, and to the great principle of attraction.

GALENICUS physician. See **PHYSICIANS** and **GALENISTS**.

GALENION, the name of an anodyne cataplasma, prescribed by *Ætius*.

GALENISTS, a denomination given to such physicians as practice, prescribe, or write, on the *Galenical* principles.

The *Galenists* stand opposed to the *chemists*. The mat-

teris medicis of the Gift is chiefly of the vegetable kind, the virtues of which they procure by the more simple and easy means; and seldom go beyond decoction; the latter take in minerals, salts, stucco, and even metals, and semimetals; these, they hold, afford more efficacious remedies; and their virtues are procured by long, arduous, laboured practices, which, with the help of fire, are obtained more pure, and to a lesser compass.

At present, the *Galenists* and chemists are pretty well accommodated; and assist our physicians with the preparations and remedies of both.

GALENISTS, or **GALENITES**, are also a branch of Menonites, or Anabaptists, who take in several of the opinions of the Socinians, or rather Ariens, touching the divinity of our Saviour.

In 1664 the **WATERLANDIANS** were divided into two parties, of which the one were called *Galenists*, and the other *ANABAPTISTIANS*.

They are thus called from their leader, Abt. Galenus, a learned and eloquent physician of Amsterdam, who considered the Christian religion as a system, that laid more stress on faith than practice; and who was for taking into the communion of the Menonites, all those who acknowledged the divine origin of the books of the Old and New Testament, and led holy and virtuous lives.

GALIEDOLON, in Botany, the name of a genus of plants described by Dillenius in his *Horae Ethnographicae*, and ranked by Linnaeus under the genus of *GALOPHILA*.

GALFOLA, in Natural History, the name of a genus of the *echinodermata*, or sea hedgehogs, of the galated or helmet kind.

They have their name from the Latin *galata*, a diminutive of the word *galea*, and which coincides with the ancient *Romana* a dish-shaped vessel, made in the shape of a small helmet. Of this genus there are three known species. 1. A papillose kind, covered with small eminences. 2. An undulated kind with its lines resembling waves. 3. The smooth kind. Klein.

GALLOPSIS, in Botany. See *Strickland* and *NETTLE*.

GALERICULATE *Anguis*. See *FLOWERS*.

GALUS. See *Blue SHIRT*.

GALUS *canis*, or *SQUALUS Galus* of LINNAEUS. See *CANIS Galus*.

GALUS *latus*, or *SQUALUS Mustelus* of LINNAEUS, the fourth-kind fish, in Ichthyology, the name of a fish of the same genus with the *galeus spinosus*, but differing in size and many other particulars. It is called the smooth hound-fish, not from any peculiar smoothness of the skin, for all the *galei* are rough in that particular, but by way of distinction from the *galeus spinosus*, as it has no spines on the back. Its back and sides are all coloured; its belly whiter; its body long and round, the end of its snout is obtuse, and runs out a great way beyond the mouth and eyes. The tail is forked. It has two fins on the back, and two pair of fins on the belly. It has, properly speaking, no teeth, but the jaws are both rough and sharp like a file.

GALUS rhodius, in Ichthyology, a name given by Arhennius and some other of the old writers, to a very large and delicate fish. Schonevelt is of opinion, that they meant by it the *Surgeon*, and brings many good reasons for his opinion.

GALUS *caninus*, or *SQUALUS spinosus*, in Ichthyology, the name of a fish of the shark kind, called in English the pickled dog-fish and hound-fish. It has a long and round body, and has no scales, but is covered with a rough skin, used by several artists for polishing their works. It takes its name from a strong and sharp spine placed just before each of the back fins.

Its back of a brownish ash colour. Its belly white and less rough, its nose considerably long, somewhat flattened, and rounded at the end. The pupil of the eye is black, of an elliptic form, and situated perfectly. The mouth is placed about the middle of the snout, and in its lower part; and it has two rows of small teeth. It is common in the Mediterranean and the English seas.

GALUS pilatus, the *flat red head-fish*, in Ichthyology, a kind of hound-fish, remarkably speckled, with white spots in form of stars.

GALIXIA, in Ichthyology, a name given by Galen and some of the other ancient writers, to the common *LAUREL-FISH*.

GALGULUS, in Zoology. See *GALUREIA*.

GALL, in the *Materia Medica*, a name given by some to the indigo, or *lignum* of the plant and used in dyeing. See *Garcia* gives us this name, and says, that the plant is like the mangrove; but Clusius translating this word by *ocymum* or basil, has strangely perverted the case; the anise or indigo plant not having any resemblance to that herb.

GALLIANS, *Gallians*, a sect among the ancient Jews,

demonstrated from *John* of *Gallus*, their chief, a way, asserting it unworthy, that the Jews should pay tribute to Trajans, raised up his countrymen against the will of Augustus, which had entered a tribute, or commutation, to be made of all his subjects.

Their pretence was, that God alone should be owned as master, and called by the name of the *Lord*; in other respects they had much the same doctrine as the Pharisees, but as they judged it unlawful to pray for rulers, they separated themselves from the rest of the Jews, and performed their sacrifices apart.

As our Saviour, and his apostles, were of *Gallus*, they were supposed to be of the sect of *Gallians*, and it was on this principle, as St. Jerome observes, that the Pharisees took a share for him, asking, Whether it was lawful to give tribute to Caesar; that in case he denied it, they might have an occasion for executing him. Vide *John* 8. Ant. Jud. lib. xviii.

GALLUM, in Botany. See *LAVANDULA* *Baldraus*.

GALLIO, *colophaea*. See *TRITACON*.

GALLI, a yellow, bitter juice, or *humour*, called also *bile*, secreted from the blood, in the glands of the liver, and deposited in a peculiar reservoir, called the *gall-bladder*.

The bile contained in the *gall-bladder*, properly called *gall*, is somewhat different from the bile deposited in the porous *hilaria*, being of a brighter yellow, a greater consistence, and more bitter and acrimonious. For the rest, the manner of secretion, with the qualities, use, &c. of the two juices, are the same; which see, under *BILE*.

After all that has been said about the bile by ancient and modern writers, there seems yet a doubt as to the true origin, and where it is generated. The commonly established opinion is, that the bile contained in the *gall-bladder* has been filtrated into it by certain glands which are found on its inner cavity. These glands, however, have been rather supposed than demonstrated, and if writers mean by them, those little protuberances found sometimes within the cyst, there is no certainty of their separating the bile, since these glands, as they are called, are wanting in many, nay in the greater part of perfect found bodies, where the viscera are in a good state, and not affected by any obstructions. When the world was beginning to believe that there were in reality no such glands as these, it was said that there were certain vessels and canals which collecting the bile from the substance of the liver, carried it to the inner surface of the *gall-bladder*, whose they opened and emptied their contents into its cavity; but these vessels have in reality been no more demonstrated to exist than the before mentioned glands, and these have sometimes appeared clogged, whose demonstration has in a manner appeared on the contrary side, to prove, that the bile is not separated in the *gall-bladder*, but is brought into it from elsewhere; of this kind there is one very remarkable instance mentioned in the *Memoirs* of the *Academy of Sciences of Paris*.

Mr. Linnæus, on dissecting a mangled body, found the *gall-bladder* to extremely thicken up in size, that he could scarce at first sight believe it was the *gall-bladder*; its neck was wholly filled, and as it were plugged up with a blackish matter, formed into a body of a spherical shape, and composed of several lobes, or layers, in the manner of those bones which are not infrequently found in the *gall-bladders* of different animals; and the other part of this body of it, which was also much the largely, was contained in a bag made by the separation of the two membranes of which the *gall-bladder* is naturally composed; this contained no fluid matter, except a few drops of a very clear water; and its inner surface, which was perfectly white, did not appear ever to have contained any bile; the cystic canals and the biliary pores, were very much dilated, and the canal as full of bile as it could hold, and the whole substance of the liver was very young, and in a state of perfect health. Now if either of the glands in the inner membrane of the *gall-bladder* separated the bile, or if any vessels transported it from the liver, and conveyed it immediately into that reservoir by apertures in its inner surface, in either of these cases all this might have been done in the bladder, though its neck were thus stopped up; but on the contrary there was no bile found there, and it would appear very plainly from this, that the bile must have some other origin, since it seems to be conveyed into the *gall-bladder* no other way than through its neck. *Mem. Acad. Scienc. Par.* 1735.

The human bile taken out of the bodies of those who died of the plague at Marseilles, was also found to be of a blackish, or deep green colour. On the mixing spirit of vitriol with it, it always became of a fine green, which colour never changed in it; and when salt, or oil of tartar were mixed in it, it always became yellow. Spirit of nitre added to it turned it black, but the colour

four-fool failed. This bile poured into a wound made in the leg of a dog, would always render him dumbly dull, and not eating or eat, and all the dogs on which the experiment was tried, died within about four days, with all the circumstances of a genuine plague upon them. Philoz. Trans. N° 170.

If half an ounce of alum in powder be added to a pound of ox-bile, and the whole stirred a little together, there rises immediately an exultation with a considerable effervescence, and the whole becomes thick and turbid like dung, and of a greenish yellow colour; but after a while, the gall will be precipitated, and its thicker parts separating themselves, and falling to the bottom, the remainder will become of a clear blue and a reddish colour. After this has stood five or six days, separate the clear liquor from the feces at bottom, and from what fouls it swims at top, and let it lie in the jar for three or four months in a cool well stopp'd; there will at the end of this time be found another precipitate at the bottom of the jar, and on the surface of the liquor, there will gradually gather together a white and hard fatty matter, and the red colour of the liquor finally will change into its primitive yellow again, and what is very remarkable, the whole will have the smell of burnt crayfish.

The observation that there is contained in this red liquor of the gall, though seemingly perfectly clear, a white fatty matter like fat, and that on the separating of this white matter, the red liquor loses its colour, and regains its primitive yellow together, proves that the substance naturally contained in the gall-bladder, is a kind of liquid fat.

The liquor of the gall appears red after its first precipitation, and loses this colour again by degrees as the fat becomes separated from it; the reason of this is, that almost all solutions of oily or fatty bodies are red, be the menstruum what it will, and this being one of those solutions must be red so long as it continues such, that is, so long as the fat remains suspended in it; but as soon as the fat is separated, the cause of the red colour ceases, and the liquor becomes yellow.

This depurated liquor of gall is one of the greatest of all remedies for freckles in the face: the manner of using it is this; mix together equal parts of it, and of oil of tartar per deliquium: to a dram and a half of each of these, add one ounce of river water, mix them well by shaking, and keep them in a well stopp'd; the end of the finger being wetted with this, is to be touch'd upon the freckled part, and this repeated three or four times a day, letting it dry on, and in length the part will look red, and there will be a sort of itching sensation felt in it; and after that, the skin will become fiery, and both that and the freckles will fall off. If this does not succeed the first time, it is to be repeated, and it will, clear the face for six or eight months, at the end of which time it is to be used again. Mem. Acad. Par. 1709.

The gall of divers animals is recommended for divers uses. That of a hog is said to revive the hair grow; and deteges and heals ulcers of the ears; that of a lamb is recommended for the epilepsy; that of the pike, for intermitting fevers; that of the carp clears and strengthens the sight; that of the eel has been administered, as it is said, with good success, for opening obstructions of the viscera, promoting urine, the menses, and labour-pains. Boerhaave relates that he has cured pale ricketty children by pills made of the gall of the eel and pike; that the medicine operated powerfully by urine, and that the belly, before swelled, subsided wonderfully; that of a kid, mixed with the white of an egg, bread, and oil of rose, and applied in form of poultice on the navel, has been extolled an approved remedy for a quotidian ague; that of a cock and a bullock, are reputed good in diseases of the eyes, and to take away freckles, and other disfigurements of the skin; that of a roe-buck, or hare, deteges and carries off clouds, specks and caracfts of the eyes; that of the goat, externally applied, is resolutive, and good in scrophulous tumours: those of the sheep, and partridge, serve to discharge and clean ulcers of the eyes. Va. River adds, that the Ashame-tum of Palestine is no other remedy, against poisons, but fetches up again drops of the gall of a goat. With a thick fluids are employed only for external purposes, a mixture of ox-bile with camphorated spirit of wine is said to be an useful embrocation for lraims, leucitis, rheumatic pains, &c.

GALL-BLADDER, *vesica*, or *fundula fellea*, is a membranous receptacle, in figure somewhat like a pear, situated at the lower margin of the liver, on the concave side; being about the length of a pullet's egg. See Tab. Angl. (Splanchn.) fig. 1. lile. c. fig. 5. lile. c. (Angl.) fig. 1. n° 33.

The gall bladder adheres to the liver, both by its vessels

which it receives from it; and likewise by its membranes, whereas the external is common with that of the liver. The lower part, which hangs out of the liver, rests on the pylorus of the stomach, which it dyes yellow with the retransfusing through its membrane.

Its fundus is raised by a fulcrum, and depressed by the emptying of the stomach, whence that usually sensation which attends hunger.

Its membrane is reckoned five: an outer, or common one, from the peritonaeum; an inner one from the capsule of the porta, and perae biliaris; and three proper ones: the first *coarctans*, consisting of white fibres, interwoven with vessels; the second, *muscular*, consisting of a double row of better fibres, the one longitudinal, the other annular; the third, or inner coat, *glandular*, consisting of a great number of glands, like the crusta villata of the stomach, which separates a mucus that lines the inside of the gall-bladder, and ascends it from the acromy of the bile.

Bot. Dr. Blake, observing a piece of dried gall-bladder, with a microscope, found little reason for this accurate distinction the several parts of Bile at the different coats appearing to be no other than an insensate pellicle of vessels directly ramified.

This bladder is usually divided into two parts: the *fundus*, or bottom, and the *neck*, or neck; at the orifice of which latter is placed a ring, or circle, of muscular fibres, which serve as a sphincter to constrict the orifice of the gall-bladder, and hinder the too liberal discharge of the bile.

The neck of the gall-bladder, being prolonged, terminates in a duct, called *musculus cysticus*, or *biliaris*, which, at about two inches distance from the gall-bladder is joined to the *maior hepaticus*, and these together form the *ductus communis*. The use of the gall-bladder is to receive the *BILE*, after it has been secreted in the glands of the liver, and to discharge it by the common duct into the duodenum.

There are four animals without gall-bladders, as deer, horses, asses, mules, camels, and apocoe fiber, the seal, and dolphin. The gall of these animals is included in ducts, which terminate in the intestines.

Mr. Petit gives us the marks, by which a distention of the gall-bladder from the bile, making an external tumor with fluctuation, may be known and distinguished from an abscess in the liver. See Mem. de l'Acad. de Chirurg. tom. I. and Med. Ed. Edinb. Abr. vol. ii. p. 491.

GALL-FISHES. See BILARY FISHES AND FISHES.

GALL-FLESH. See BILARY CONCRETIONS AND STONES.

GALL-FLESH, or stone concretions of earthy matter and bile that are found in the gall-bladder, or in the ducts of vessels, are used in the arts when these are rubbed with water, and troed as GALL-STONE, they yield a deep warm yellow, which on account of its brightness and dark shade, as well as durability, is very valuable. A delicious kind of gall-flesh may be prepared in the following manner: take a quart of the fresh bile of oxen; hold it with a quarter of an ounce of clear gum arabic in a pewter vessel in *balneo Mariae*; evaporate the whole to about an eighth, and remove the remainder into a china cup or balon, and evaporate it to dryness, collecting it into a mass as it becomes of a stiff consistence. This being more transparent, will be found of very great advantage in water-painting.

GALL is also used by naturalists to express any protuberance, or distortion of a part of a leaf, or stalk on a tree, or plant, occasioned by an insect living and growing within it. These are all monstrous and unnatural productions of the vegetables that bear them; but they often are so regular in their formation, that they have the appearance of fruits and flowers. On examination however it will always appear, that they are fruits containing no seeds, and flowers the product of which is animals. Among the smaller insects, there are many which enter in the whole life of the worm, or in a part of it, are so tender and delicate a structure, that they cannot bear the contact of air, and others that are continually exposed to the ravage of a number of destroyers; so that by one or other of these means they could never live to arrive at maturity, or to propagate their several species. Provident nature has therefore allotted for the habitation of these the gall of trees and plants; they never however find experiences ready formed, but by their own action make them for themselves. Some of these insects are produced from eggs laid by their parent animal on the stalks of leaves or plants, and as soon as ever they are hatched from these, make their way into the leaf, or stalk, and find a safe lodging in this recess, and necessary food in its juices; others are lodged even in the egg-tube within the substance of the leaves and branches, and have no occasion for eating their own way in.

in. The parents of these are a peculiar race of flies, which have at their tail an instrument prepared for this purpose; with this they pierce the surfaces of vegetables, and lay their eggs in the holes they have made, so that the worms hatched from these have nothing to do, but to gnaw the tender fibres of the vegetable, and feed on the juices extravasated from the apertures they make in them. Reaumur, Hist. Inf. vol. vi. p. 176.

The manner of the production of *galls* is well described by Malpighi, in an exquisite treatise De Gallis. The process, as observed in the cone-galls, or apples on the gums of oaks, is also given us by Dr. Derham.

These cones, says that author, are in outward appearance perfectly like the galls or buds themselves, only vally bigger; and in effect, they are no other than the galls swelled out in bulk, which naturally ought to be pushed out at length. The cause of this obstruction of vegetation is this: into the very heart of the young tender bud, which begins to be turned in June, and shoots out in a month more, an insect, of the ichneumon fly kind, thrusts one, or more eggs; and, in all probability, some venomous ichneumon. This egg soon becomes a maggot, which rats itself a little cell in the very heart or pith of the gum, which should be the rudiment of the branch, leaves, and fruit.

The branch thus destroyed, or, at least its vegetation obstructed, the sap that was to nourish it, is diverted into the remaining parts of the bud, which are only the leafy teguments, and which by this means grow large and flourishing, and become a covering to the insect case, as before they were to the tender branch.

The case lying within this cone, is, at first, but small; but, by degrees, as the included maggot increases, so does the case till it becomes to the size of a large white pea, shaped like an acorn.

It may be added, that even noles, ground-ivy, &c. have a kind of balls or cases produced on their leaves, by the injection of the eggs of a fly of the same kind. These cases always grow in, or adjoining to, some rib of the leaf; and their production Malpighi and Dr. Derham describe thus:

The parent-insect, with its stiff fecerous tail, bores into the rib of the leaf, when tender, and makes way for its eggs into the very pith or heart thereof; emitting along with them a proper juice to pervert the regular vegetation.

From this wound rises a small excrescence, which, when the maggot is hatched, increases and swells on each side the leaf, between the two membranes; extending itself into the parenchymous parts thereof, till it be grown as big as two grains of wheat. In this case lies a small white, rough maggot, which turns to an aurelia, and afterwards to an ichneumon fly.

The *galls* caused by different insects have a very different internal structure, some of them have only one large cavity within, in which a number of the animals live in community, others have several small cavities with communications between each, and others have different numbers of little cells each separate, and having no communication with the others: there are sometimes a hundred of these cells in one *gall*, sometimes only two or three; and finally, there are others in which there is only one cavity inhabited by one insect. The clearness of these two last kinds, live in perfect solitude during the worm state, and can have no knowledge of any other living creature besides themselves, till they have passed through the intermediate state of chrysalis, and become winged animals, like those to which they owed their origin, and are ready to lay eggs themselves.

The general division of *galls* into these classes, admits of a vast number of subdivisions under each, of the different figure and confidence of the several species. Some of them are so hard, that they equal, or exceed the hardness of the wood of the tree they grow upon; and when cut, appear composed of fibres, much more densely and closely arranged: others are soft and spongy, and resemble some of the tender fruits in appearance.

The first kind are usually called *gall-nuts*, and the latter *apple-galls*, or *berry-galls*. The common *galls* used in dyeing, are of the first kind, and what are called *oak-apples*, and *oak-grapes* are of the latter. The oak produces several of this last species of *galls*, some of which are oblong, others round, resembling grapes, gooseberries, and other fruits; these are also usually beautifully coloured, some being of a bright red, others of a bright yellow.

These *galls* of the oak, are of the austere taste of the juices of nature; but those of other plants, are often well-tasted. There is a species of *gall*, well known by the name of *apple-gall*, the leaves of which afford a lodging to the worm of a peculiar species of fly, and this *gall* grows to a very considerable size, so as to have obtained the name of an apple from its resemblance to this

fruit; these are eaten by the people of the eastern nations, and are commonly sold in the markets of Constantinople, and other places. A plant very common with us, the ground-ivy, has the same property; its leaves are often loaded with *galls* on their under side, which are very green and juicy, and of no disagreeable taste. Mr. Reaumur gives us an account of their being one year so plentiful in the neighbourhood of Paris, that the poor people eat them, both raw and boiled, as food. See *Tab. of Insects*, N° 25. seq. Reaumur, Hist. Inf. vol. vi. p. 182.

The round *galls* are by far the most numerous class of all others; but these have great differences in their appearance: some are perfectly smooth on the surface; others are very rough and knobby, some adhere immediately to the leaf or stalk of the vegetable; and others are placed on a longer or shorter pedicel. Some are whole on the surface, which show that the creature by which they are formed is still contained in them, and others are perforated, so that the animal has escaped.

There are two principal kinds of *gall-galls* in our shops, and used in dyeing, making ink, staining, &c. one said to be brought from the Levant, and the other from some of the southern parts of Europe, particularly Sicily and Romania. They are nothing else than the cases of insects, formed of the juices of the oak-tree, issuing out through small wounds made by these insects, in the manner already described. See an account of these insects in Philoz. Trans. N° 245. and *Gall-insect* *testis*. These excrescences are not formed on any particular species of the oak-tree; for Mr. Ray says, that he has seen them on the same kind of oak with that which is common here. The first kind, called *Aleppo galls*, and in the shops of the dyers called blue *galls*, are generally of a bluish colour, or of a greyish or blackish verging to blue-ness, unequal and warty on the surface, hard to break, and of a close compact texture. The second kind, commonly called white *galls*, are of a pale brownish or whitish colour, smooth, round, easily broken, less compact, and of a much larger size. The two sorts differ in strength, but in other respects they appear to be of the same quality. The *Aleppo* or blue *galls* are the strongest; two parts of these are reckoned by the workmen to be equivalent to three of the white, and Dr. Lewis apprehends that the difference in their strength is greater than in this proportion. The strongest and colouring matter of *galls* is dissolved and extracted from the subject both by water and spirit of wine, and does not exhale in the evaporation of the liquors by heat. From sixteen drams of *galls* fourteen drams were extracted by water, and from the same quantity twelve drams and two scruples by spirit.

Galls, with regard to their medicinal use, are found to be very astringent, and good under proper management in diarrhoea, dysenteries, and hæmorrhages of all kinds. They have also a great virtue as a *verrufigent*, and are often found to cure an interment. In fevers half a dram or more of the powder of *Aleppo galls* may be given for a dose. They are also used externally as a strengthener, and astringent; a decoction of them is applied with success by way of fomentation in *prolapsus of the anus*, and has been injected in the *fluor albus* with great success.

Galls may be made a very useful test for iron in the several species of vitriols; for it is certain that an infusion of *galls* will become black with a solution of any vitriol that contains iron, and not at all with such as contain only copper, as the common blue vitriol and the like.

Dr. Lewis observes, that if a decoction or infusion of *galls* is dropped into a solution of this vitriol, largely diluted with water, the first drops produce bluish or purplish red clouds, which mingling with the liquor tinge it uniformly of their own bluish or reddish colour. With distilled water, or the common spring waters, the mixture is always blue; but if the smallest portion of alkaline salt be dissolved in the water, or if the water is in the least degree putrid, the colour produced will be purple or reddish. If more of the astringent infusion be added to the blue or purple liquors, they will deepen to a black, which will be more or less intense according to the degree of dilution; and the colouring matter may be separated from the liquors, unless they are of a full blackness, by dilution with water and deposition. The separation may be repeated or prevented, as is done in the preparation of ink, by adding some mucilaginous matter, as gum Arabic. This coloured matter is evidently a feruginous precipitate; for, although it cannot be attracted by a magnet, this property may be given to it by a light calcination. This precipitate is soluble by acids, as in the case of ink, whose colour is hereby destroyed, but it may be restored by the addition of alkalis. Lewis's Com. Phil. Techn. p. 344, &c.

GALLI, Ite, in *Natural History*, the name given by authors to a very singular kind of *galls*, of a couple figure, with a conic top, of a cone resembling a wooden box, and enclosing a white worm in the manner of the other vegetable lodgements of the same kind: this sort of *gall* is found only on the leaves of the *LAME-YARRE*. Reaumur.

GALLI, branch, a species of *galls*, found on the branches of the common wild bramble. These are often no other than justifications of the stalk, for the space of an inch, or thereabout, which sometimes form only so many thick cylindrical pieces; at other times they are of the shape of an olive, and sometimes they affect only one side of the branch: in all cases, however, the tumid part, or *gall*, is much harder than the other parts of the branch, which are in their natural state. They are inhabited by a great number of worms, of an oblong figure, and yellow colour, which have a sharp point, of a brown colour, and of the hardness of iron, proceeding from the extremity of the head, with which they tear and break the woody fibres, and near its end there is a bit, which is the mouth of the creature, and serves for receiving and conveying into the branch, the fragments of wood which it breaks with the point. Reaumur.

GALLI, beam. See **BROOM**.

GALLI, line. See **LINE**.

GALLI, myriam. See **MYRIAM**.

GALLI, poultry. See **GOOSEBERRY**.

GALLI, grape. See **GRAPE**.

GALLI, cat-in. See **CAT-IN**.

GALLI, red. See **RED**.

GALLI, wine. See **WINE**.

GALLI, wind. See **WIND**.

GALL-INSECT, in *Natural History*, the name of a class of insects, so called, from their resemblance to small *galls*, or vegetable protuberances of a like kind upon trees. They are indeed in like these tubercles, as to have been by many mistaken for them, and thought not of the animal, but of the vegetable kingdom. These insects pass a very great part of their life, even many months together, fastened against the leaves or stalks of plants, without any appearance of life or motion, and this is the time in which they acquire their fixed growth. They are in this state as immovable as the branch they are fixed on, and seem to make a part of it. Their exterior form is remarkably plain and simple, and the more the creature increases in growth, the less appearance of life it shows; and even when it has acquired its maturity, and is in a condition to deposit its eggs, for the propagation of its species, it then appears both of all of an animal form, and more, than in any other state, resembles a *gall*, or such vegetable protuberance. Not only the vulgar and ignorant have been deceived by this appearance, but the accurate count Marzulli, among others, after very attentively examining the *gall-insects* of one species, remained seemingly convinced that they were real vegetable excrescences.

They are usually found on the stalks and branches of trees, shrubs, and perennial plants. They are very various in size, shape, and colour.

These creatures have so little to attract the observation even of the curious, that they might probably have remained much longer unperceived, were it not that they multiply so excessively fast on some fruit trees. The peach-trees, in particular, are sometimes in a manner covered with them, and these of more than one species; some of the globular kind, and others of the boat figure. The branches thus covered look rough and scabby, and the gardeners, sensible that whatever the things were, they must be noxious at the expense of the juices of the tree, have attempted to destroy them. The leaves and fruit of these trees are often blackened by the use that has run off from their insects; and our orange-trees, which are frequently full of them, first attract the attention of the more careful observers of them to clear them away: these are principally of this kind, whose form is that of the inverted boat. Melici, de la Hire and Solides were at the pains of making a set of observations, of a very curious kind, concerning them; these gentlemen call this species the *orange-tree-gall*, a name by which the gardeners also call them, though they have nothing in common with any known species of that animal. See the *Memoirs of the Academy of Paris*, 1694. If many of the species of these little animals, however, do mischief to our fruit-trees, there are some other kinds of them, the value and use of which may very well make us amend; for it is from some species of these little creatures, that the inhabitants of many places make such great gains, gathering a harvest of them without the trouble or expense of sowing or cultivating. The *TERMINA*, so well known by name, though so little truly understood, is of this kind, to

Vol. II. No 146.

which both the physician and the dyer are so greatly obliged. Reaumur's *Hist. Insect.* vol. iv. p. 1.

Dr. Liller was, perhaps, the first discoverer of the *gall-insect* and *gall-insect* classes: he found these animals on the plum, cherry, vine, laurel, and many other trees, and calls them *gall-insects* of these trees. He was well apprised of their animal origin, and in the year 1761 discovered that some of them would strike a crimson-red colour, with lay of *stiles*, which was not only a good but a permanent tinge. The principal knot on which he made the experiment was the hemispherical fort, which he describes as being entirely round, except when they are applied to the trees. They were of the size of half a large pea, of a chestnut colour, and of a shining surface, fastening themselves to the bark of the tree, as the limpets do to the rock, and were generally fought after by ants and other vermin.

GALLI, peach-insect. See **PEACH**.

GALLI, shell-insect. See **SHELL**.

GALLI, vine-insect. See **VINE**.

GALL-INSECT, *fly*, the male of the *gall-insect* species. It is a two-winged fly of a very particular kind. There seems a great resemblance between these flies in all the *gall-insect* class, and that of the *BEACH-POLLARD* may give a proper idea of all the rest. This little creature, examined with the help even of the best glasses, shows, on the under part of its head, nothing analogous to the organs of other flies, destined to convey their nourishment; nothing that at all resembles the trunk of the other two-winged flies, nor any thing that can be compared to teeth. Where the teeth, if any, ought to be placed, nothing is to be seen but two hemispheres, or more than hemispherical bodies, black and shining, and in all respects resembling eyes. If these are eyes, they are very remarkably situated; and just over against them, on the other side of the head, and near the base of the antennae, there are two other similar bodies, which indeed cannot be taken for anything but eyes. It should seem that this fly has therefore no organs to receive aliments, but has two eyes in the place of such.

The want of these organs is nothing singular in the insect world, since the moths and butterflies afford us instances of it. Many of these may be seen, as soon as produced from their chrysalis, in a state to propagate their species, and deposit their eggs; and this great end achieved, they have no farther occasion for life, nor any means for its support; and probably the case is the same with these flies, which as soon as loose from their shell, feed out and fecundate the females, and have after this no further use for life. It is another singularity in this species, that they are produced from their shell by their hinder part first, whereas all other species of the two-winged flies are produced with the forepart of their body first; and if we cannot by what may be the reason for this singularity in the production of this fly, we can however easily perceive that every thing is prepared and destined accordingly for it. In the nymphs of other flies, all the legs are constantly applied close to the body, whereas on the contrary, in the nymphs of the *gall-insect* fly, the legs placed next the head, or the first pair, are constantly ranged upward, and each of them embraces one side of the head; the constant position of these legs in this direction, is a proof that it is the order and course of nature in the production of the animal; not is it without reason that they are thus placed in a species which, contrary to all the others, is to force itself backward out of its shell, since they serve very properly for the creature to push himself backward by, and as the posterior part of the cases of other flies naturally and easily opens, to give passage to the animal, so the posterior part of this does. They seem also to be more than ordinarily slow in their getting out, some of them having been observed to be ten or twelve hours, from the time of the first appearance of a piece of each wing, to their perfect enlargement. Reaumur, *Hist. Insect.* vol. iv. p. 48.

GALLA. See **GALLI**.

GALLANT, or **GALANT**, a French term, signifying civil, polite, well-bred; or a person of wit and address, who does every thing with a good grace: in fine, a civil person, somewhat brighter, gay, and more agreeable than ordinary.

It is difficult to define all the qualities annexed to the idea of a *gallant* man. It sometimes implies one who has what the French call the *bon ton*; but it generally means one who has a great devotion for the fair sex, with the manners adapted to please them. The French authors are very nice on this point; they distinguish *galant homme*, and *bon galant*.

GALLANTE, among the Romans, a surname given to the priests of Cybele; whence the modern terms of *galant*, and *galante*.

low, and gallantry, have been formed. See *Mém. Acad. Inscrip.* vol. v. p. 417.

GALLIED, *gallicus*. See *SARDINIA-gallic*.

GALLIED, in Sea-Langage, is applied to a mast, yard, cable, &c. which is chafed and worn by friction. They are usually covered with skins, mats, canvas, &c. in those parts which are the most exposed by the rocking of the vessel, as a precaution from this injury.

GALLION. See *GALLION*.

GALLERICA *lapia*, a name given by the writers of the middle æge to a species of emerald, which was larger than the *Swiss gems* of that kind, and of a pleasant green, but debased by an admixture of white.

GALLERY, in Architecture, a covered place in a house, much longer than broad, and which is usually placed in the wings of the buildings, and serves to walk in.

Sarcot, in his architecture, derives the word gallery from *Gaul*, as supposing the ancient Gauls to have been the first who used them. Nicod fetches it from the French *aller, to go*; *g. d. aller*; others bring it from *galley*, *galley* because it bears some resemblance thereto in respect of length. In the corrupt Latin we meet with *galatras*, for the gallery of a monastery.

The galleries of the Louvre are magnificent; a gallery of painting; a complete apartment is to consist of a hall, ante-chamber, chamber, cabinet, and gallery.

GALLERY also denotes a little office, or walk, serving as a common passage to several rooms placed in a line, or row.

The gallery of a church is a kind of continued tribune, with a balustrade, built along the sides or lower end of a church, to make it hold the more people; and, in the Greek churches, to separate the women from the men.

GALLERY, in Fortification, a covered wall, or passage, made across the ditch of a town besieged, with timber pilasters on the ground, and planked over. See *Tab. VII. Fortif. fig. 46*.

The sides of the gallery are to be mulquet-proof, and to consist of a double row of planks, lined with plates of iron; and the top is sometimes covered with cards, or turf, to hinder the effect of stones, artificial fires, &c. of the enemy.

Galleries are chiefly used to secure and facilitate the miners approach to the face of the bedrock, over the point, which is already supposed filled up with supports and pillars, and the artillery of the opposite flank dismounted. Sometimes this is called a *reefery*.

GALLERY, in Gardening, is a kind of covered walk, which is to be made in the following manner. A line is first to be drawn to the length of the intended gallery, and this is to be planted with boxwood, which is to be the foundation of the gallery. There require no further care than to be secured a sides, and sometimes digged about, as there may be occasion. But the chief curiosity is in the ordering the face-part of the gallery, and forming the arches. The pillars of the porticoes, or arches, must be placed at four feet distance from one another, and the gallery must be twelve feet high, and ten feet wide, that there may be room for three persons to walk abreast in it.

When the boxwoods are grown to the height of three feet, the distance of the pillars well regulated, and the ground-work of the gallery finished, the next thing is to form the transmissives, to perform which, the boxwood must be hewn between two pillars as the height, and a trellis, made for that purpose, must be run up, which forms the arch. As it grows up, these branches which out-top the others must be levelled with the ficaria, and in time they will grow very strong, and may be kept in regularity by the ficaria. Porico *gallorum* may be covered with lime-trees.

Galleries in general have been always but lightly esteemed in England; they were once very much in repute in the gardens of Italy, and other hot countries, but now they are got out of credit every where. Miller.

GALLERY of a mine denotes the *branc*, or that narrow passage underground, leading to a mine carrying on under any work designed to be blown up.

The beggers and beggied do each of them carry galleries, or branches under ground, in search of each other's mines; and these sometimes meet and destroy each other.

GALLERY in a ship, is a kind of balcony, made upon the stern, without board, into which there is a passage out of the great cabin. See *Tab. Ship. fig. 1. in m. fig. 2. s. 68. and 101*.

These galleries are for show, and the captain's pleasure, rather than any other benefit; for, in times of war, all open galleries of this kind are to be avoided; on account of the facility of an enemy's entrance, and boarding of the ship that way.

GALLERY-gallery, in Ship. See *LADDER*.

GALLERY, gallery, in Whistling place.

GALLEY, in Chemistry, is the name given to reverbera-

tory furnaces, in which several vessels may be placed at the sides at each other. They are called, because they are oblong, and have lateral openings, in which they are supposed to resemble galleys.

GALLIES, in Naval Language, a low-built vessel, going both with oars and sails; chiefly used by the Romans, but also by the Mediterranean.

The galley is called by the Greek authors under the eastern empire *galeas*, and *galeas*; and by the Latin authors of the same time, *galia*; whence the modern denomination. Some say, it was called *galia*, on account of the figure of a cork or helmet, which it bore on its head or prow, as Ovid asserts, *De Tristibus*. The French call it *galie*; because they say, that the top of the mast is usually cut in manner of a hat, which the Italians call *galie*. Others derive both *galie* and *galia* from a fish, by the Greeks called *galaxius*, or *galax*, and by us the *finch*, while others think *galie* *galaxius*. Lastly, others derive *galie*, *galia*, *galie*, *galie*, &c. from the Syriac and Chaldean *gal* and *galia*, a man exposed on the water, or in a vessel of wood.

The largest sort of these vessels, called *galies*, is employed only by the Venetians. They are commonly one hundred and fifty-two feet long above, and one hundred and thirty-three feet by the keel; thirty-two feet wide, with twenty three feet length of stern-post. They are furnished with three masts, and thirty-two banks of oars, every bank containing two oars, and every oar being managed by six or seven slaves, who are usually chained to it. In the fore-part they have three little batteries of cannon, of which the lowest is of two thirty-six pounders, the second of two twenty-four pounders, and the uppermost of two two-pounders; three English powder magazines placed on each quarter. The complement of men for one of these galleys is generally a thousand, or twelve hundred. They are very convenient for bombarding, or making a descent on an enemy's coast, because they draw little water; and on account of their oars, they have often the advantage of ships of war in light winds or calms, by extending the latter over the surface of the water, by securing their whole length with their oars, and at the same time keeping on their quarter or bow, to sail to leeward of the direction of their current. The galley next in size to these, called *galea*, are from one hundred and twenty to one hundred and thirty feet long, eighteen feet broad, and nine or ten feet deep. They have two masts, which may be struck at pleasure, and are furnished with two large lateen sails, and five pieces of cannon; they have commonly twenty-five banks of oars, as already described. Those of a size still less than these are called *quarto-galleys*, carrying from twelve to sixteen banks of oars.

All the galies, both ancient and modern, are of a finer and swifter make than ships. Formerly they made divers kinds; at present the galies are all alike: all the difference between them is in size, and making as to figure. They usually keep towards the wind; though sometimes they cross the sea.

The king of France keeps up forty galies for the use of the *Allegoragion*, the annual festival being at *Antiochia*. The general of the galies bears double anchors, placed in pale behind the elevation of his man, as a mark of his office.

Galleys in Latin are called *galeas*, *galeas*, and *galeas*; not on account of their having two, three, or four ranges of oars before one another, as many learned men have imagined, and particularly Scalliger and Suetonius, though this last has written excellently on the subject of navigation; for this was impracticable, not yet on account of their having but two, or three, or four oars, for then they would want strength; but because these were two, three, or four masts, sufficient to sail on, as in the galley used among us; it is very well known by the *Joint Decades*, in his Art of Building. The error was occasioned by some ancient galley, represented on medals, or bas-reliefs, wherein are several ranges of oars placed over each other; but all the moderns, pilots, and ship-builders, look on this as a mere vision; inasmuch as Pliny makes mention of galies of fifteen, twenty, thirty, forty, fifty rows of oars; so that, if they were ranged over each other, though we were only to allow four feet for each oar, there would be a distance of one hundred and fifty feet between the lowest rowers and the highest; and yet we are told, that the highest rower could not see the lowest rowers.

Scalliger affirms, that the first *TRIMAST*, or galley of three masts, was built at Corinth; and is a testimony, that the first galley was *fig. 1*, were what we call *quarto-galleys*; the first wharfed was that of the Argonauts. Vegetius mentions a galley of five decks; and Mennius, another with eight; and only one man to each oar. See *EXPLAN.*

GALLEY,

GALLERY, captain, is the principal *galley* of a state, commanded by the captain-general of the *galley*: in France the *royal galley* is the first.

GALLERY, patron, denotes the second *galley*, both of France, Tuscany, and Malta.

The second general of the *galley* is always on board the *royal galley*; and the lieutenant on board the *patron*. The terms peculiar to *galley* are very numerous, and make a new system of terminology, different from that used in ships.

Mout-de-l'etat, an ancient officer on board the king of France's *galley*, engaged himself in writing a new dictionary of the dialect of the *galley*.

GALLEY, condemnatoire à vie, is a penalty imposed on criminals and delinquents, particularly in France; whereby they are allotted to serve the king, or state, as slaves on board the *galley*, either for ever, or for a limited time.

Condemnation to the *galley* for ever imports confiscation of lands, goods, &c. (as in France, that which confiscates the person, confiscates the goods).

A man condemned to the *galley* for perpetuity, is dead in a civil sense. He cannot dispose of any of his effects; cannot inherit; and, if he be married, his marriage is null; nor can his widow have any of her dower out of his goods.

The ecclesiastical courts cannot sentence to the *galley*; it is out of their jurisdiction.

By an ordinance of Charles IX. in 1564, the judges are enjoined not to condemn a criminal to the *galley* for less than ten years; and Hen. III. by another of 1579, enjoins the capitans not to detain their *galley-slaves* after their time is expired. But neither of these laws are now observed.

GALLEY, in Printing, a wooden frame, or instrument, formed of an oblong square board, with a ledge on three sides, and a groove to admit a false bottom called a *galley-flute*, into which the compositor empties the letter out of his composing-stick, as often as it is filled.

The *galley*, when filled, contains the matter of one page; and when they have composed as many pages as are required for a whole sheet, half sheet, or the like, they impose them, i. e. they take the several pages out of the *galley*; put them into a chase; lock them up with the furniture; and so make forms ready for the press.

GALLEY-halfpence, a kind of coin, which with *solins* and *deniers*, were forbidden by the statute 3 Hen. V. cap. 1. It is said they were brought into this kingdom by the Genoese merchants, who trading hither in *galleys*, lived continually in a lane near Tower-street, and were called *Galley-men*, lending their goods at *Galley-money*, and trading with their own small silver coin, termed *galley-halfpence*.

GALLI, or GALLA, in *antiquity*, a name given in Thracia to the country-priests of the goddess Cybele.

The principal of them was called *archi-Gallus*. The *Galli* were also called *Dactyle*, *Idæi*, *Coribæti*, &c. Authors are not agreed as to the reason of this denomination. Some derive the name from the river Gallus; because these priests drank of its waters, which inspired them with a kind of religious fury and enthusiasm, and deprived them of their senses to such a degree, that they mutilated themselves.

Others hold, that the first priest of Cybele having been named Gallus, the name became appropriated to all his successors. Yossius, who proposes these two opinions, seems to incline most to the latter; though Ovid, in the fourth of his *Fasti*, and Herodian, lib. i. favour the former.

When youth were initiated into this order, the custom in Syria, according to Lucian, was to throw off their cloaths, to make loud cries, and with drawn swords to castrate themselves: after which they ran about the streets, carrying in their hands the marks of their mutilation, which were thrown into a house, and in that house they put on women's dress.

These priests threw themselves into a kind of phrensy, when they performed the ceremonies of the goddess; apparently, in imitation of the young Atys, her favourite, whom they likewise imitated, by mutilating themselves. For authors relate, that Cybele being desperately in love with that young man, she gave him the superintendence of her sacrifices, on condition he would keep his virginity; but that soon after, to get rid of his promise, he had an affair with the nymph Semele, that Cybele, provoked hereat, struck him mad; that in a vehement passion of his passion he was going to kill himself; and that the goddess, perceiving, returned him to his understanding; that out of his own remorse, he castrated himself; and that after his example all the priests of Cybele from that time did the like.

Their phrensy, at the same time of the sacrifices, consisted in throwing round the head with great rapidity, and

making violent contortions of the whole body: they had also drums and flutes, wherein they played, and danced to them; as already observed under the articles *CORYBANTES*, and *CORYMBES*.

GALLI, capital. See *CAPUT*.

GALLI, civitas. See *CRISTA*.

GALLIAMBIC, in the *Ancient Poetry*. *Gallambic* pen is a composition in *Gallambic* verse.

GALLAMBIC verse, a sort of iambic, consisting of six feet; 1. an anapaest, or a spondee; 2. an iambic, or an anapaest, or a trochee; 3. an iambic; 4. a dactyl; 5. a dactyl; and 6. anapaest.

Though poets might measure the *Gallambic* verse in another manner, and make a different arrangement and combination of syllables, which would give different feet. It is certain the ancient regarded little more in the *Gallambic* verse, beside the number of measures, or feet, without troubling themselves about the number of syllables, or the kinds of foot whereof it was composed.

GALLIAMBUS, in *Poetry*, a pleasant kind of verse, used to be sung by the Galli, priests of Cybele, in honour of that goddess.

The word is a compound of *Gallus*, a peck of Cybele, and *iambus*, a foot in the Greek and Latin verse. *Gallambus* also denotes a piece or composition in *Gallambic* verse.

GALLIANA, in *Natural History, a name given by some authors to the *TURQUETIA* rose. It is only a corruption of the word *calluna* *gemma*, a name of this flower common among the Roman authors.*

GALLIARD, or GALLIARDA, in *Music and Dancing*, a sort of dance, anciently in great request; consisting of very different motions and actions, sometimes proceeding *terra à terra*, or smoothly along; sometimes capering sometimes along the room, and sometimes acrobatic. The word is French, *gallier*, or rather Italian; and literally signifies gay, merry, sprightly. This dance was also called *Ramagay*, because brought from Rome.

Thoinot Arbeau, in his *Orcheography*, describes it as consisting of five steps, and five postures of the feet, which the dancers performed before each other, and whereof he gives us the figure, or tabature, which is of six minutes, and two triple times.

GALLIARDA, in the *Italian Music*, the name of a tune that belongs to a dance called a galliard. The air of it is lively in triple time.

GALLICAN church denotes the church of France; or the assembly or convocation of the prelates of France.

M. de Fin has an extensive treatise of the liberties of the *GALLICAN church*.

GALLICAN library denotes the library used by the church of Agrigento, in Sicily; which the modern writers call *Bretharium Gallicanum*.

The reason, no doubt, is its having been introduced by St. Celsus, who was made bishop of Agrigento, after earl Roger had been driven out of Sicily by the Saracens; and by the other French bishops, which the Norman princes brought thither. See *BARBARY*.

GALLICAN liturgy is the manner of performing divine service, anciently observed in the Gauls.

Fr. Mabillon shows wherein it differed from the Roman liturgy. 1. Liturg. Gall. cap. 5, &c.

GALLICAN night. See *MASS*.

GALLICISM, a phrase, or construction, peculiar to the French language; or which has something contrary to the ordinary rules of grammar or other languages.

Thus, *Cet homme est son leecher*, is a *Gallicism*, having no regular construction; and the same may be said of *Faire de la terre le fust*; which no grammar could ever find out.

With us it is used to denote such phrases or modes of speech in English, as are formed after the French idiom.

GALLIGASKINS, in our *Old Writers*, denote wide hose or breeches, having their name from their being used by the Galcoigns.

GALLIMATHIAS, a dark, perplexed discourse, where words and things are huddled together, so as to make an incommunicable jargon.

The word is French, formed as some will have it, from *gammathia*, which signifies diversity of sciences; because such as have their memory burdened with several kinds of sciences, are usually confused, and express themselves ill. M. Hoet rather takes the word *gallimathias* to have had the same origin with *allotrius*; as to have first arisen at the time when all the pleadings in the bar were in Latin. There was a word, it seems, upon the carpet, about a cock, belonging to the plaintiff Mathias; this couleir, in the text of his harangue, by often repeating the words *gallus* and *Mathias*, happened to Vaudier; and, instead of saying *gallus Mathias*, said *gall Mathias*; which at length became a general name for all confused, embroiled language, and discourse.

CALLIMAWFRY, a ragoo, hutch, or hotch-pot, made of the remains of several kinds of meats.

The word is French, *callimawfré*, which signifies the same.

Hence the word is also used in a figurative sense for a piece, or composition, of several different parts, ill digested and embroiled.

GALLINÆ, in the Linnaean system of *Ornithology*, the name of a large order of birds, the general character of which is, that their beak is conic and bent; the upper mandible is arched, and extends beyond the lower; the nostrils are half covered with a cartilaginous convex membrane; the feathers of the tails are more than twelve, and the feet are cloven; but the outmost and inner toes are connected by the first joint of the middle toe by a small membrane. The *ODOBO*, *PRACOCK*, the *milvæ* of TURKEY, the *CRAX*, the *PHALANX*, the *milvæ* *Nuvidæ*, or *GUINAE*-*hen*, and *TETRAO*, are of this order.

GALLINA Guineæ. See *GUINAE*-*hen*.

GALLINA Mexicana, in *Ornithology*, a name under which Nierenberg has described a sort of hen, which he says has not only black feathers, but black flesh, and black bones: a history Mr. Ray sufficiently explores.

GALLINA sibilis, in *Ichthyology*, the name of a fish of the caracoi kind, more usually known by the name of the *seras pilote*.

GALLINACEOUS, in *Ornithology*, the name of a species of birds of the pheasant kind, including the common cock and hen, the characters of which are these. The beak is short, strong, and a little hooked, proper for the picking up of corn, which is the food of the whole species; the body is large, thick, and fleshy; the wings are short and hollowed, and not calculated for much flying; they all breed a numerous progeny; they build on the ground; the young are not fed by the parent, but immediately flit for themselves; and some having spurs behind their legs. See *COCK* and *POUL*.

GALLINAGINIS *specie*. See *CAPTIV*.

GALLINAGO, a general name for Heath fowls, as the *WOOD-CK*, *WINTER*, &c.

GALLINAGO minor. See *SHRIMP*.

GALLINE, in *Ichthyology*, a name given by the Maldivians to the flying-fish, called by authors *milvus* and *teranus*. It is a species of *TRIGLA*, and is distinguished by Aristotle by the name of the *trigla* with the foot somewhat bluish at the end, and the lateral lines forked towards the tail.

GALLING, in *Medicine, *Intestines*. Children are subject to inflammations and excoriations in several parts of their bodies, particularly behind the ears, in the neck, and thighs. Those in the lower parts usually proceed from the acrimony of the urine, which sometimes frets off the epidermis, and leaves the cuts bare. The cure may be accomplished by washing the parts gently with warm water, twice or thrice a day, which dissolves and drinks off the acrimonious salts of the urine lodged therein. Nurtice usually dissolve a little fuller's earth in the water, and apply it to the part after being well washed. Cerate, chalk, or calined flax, finely powdered, will also serve for the same purpose. But where the inflammation and excoriation are considerable, it is proper to use, by way of fomentation, a solution of *rubus* *albi* *Rhubi*, in chaurin water, twice or thrice a day. In the mean time the parts should by all means be kept dry, or prevented from rubbing against each other, by the interposition of fine linen rags, or the use of a little red deffecative ointment, or diaphanophyllos, spread thin upon it.*

Galling, produced by the wringing of uneasy shoes, are mollified and kept from swelling by the application of the lungs of a swine or lamb, warm, to the grieved part. Effectual for the same purpose, is the powder of a burnt old shoe sprinkled on the place, or raw wool, or the flowers of the garden pomgranate, each of them burnt, and the ashes sprinkled thereon; or scarra rubbed on the galled part with vinegar. To those who have tender flesh apply the *emplantum ex herba*.

For *galling*, burnt, and eruptions of *popule*, a moist excellent plaster is prepared of three ounces of litharge, four ounces of wax, one ounce of rectified wine's oil, and a pound of oil of myrtle; to induce a cicatrix, omit the fat in the prescription. *Antia*, *Tetrab*. 4. *Serm.* cap. 67.

Belaslines are much commended by Orribian for speedily cicatrizing *gallies* and old ulcers; the bark of the pine-tree, also, is said by the same author to be excellent for *galling*, being applied to the place. *James's Med. Dic.*

GALLING. See *BARE-GALLING*, *SADDLE*, &c.

GALLINULA, in *Ornithology*, the name of a genus of birds which swim on the water, and yet have not webbed feet, nor any membranes joined to their toes, to augment their breadth. The bill is thick at the base, sloping

to the point, the upper mandible reaching far up the fore-head, and callosa; the wings are short and concave, the body compressed, and the toes long, directed to their origin. The common moor-hen, and a great number of other birds, both English and exotic, are of this genus, as the water-rail, the grebe, the ochropus, and several Brazilian birds.

GALLINULA erythraea, in *Ornithology*, a name given by many authors to the bird commonly called in English the *RED-NECK*.

GALLINULA hypoleuca, in *Ornithology*, a name given by some authors to the beardless, or, as we call it in English, the *SANDPIPER*. See *TRINGA*.

GALLINULA melanota, in *Ornithology*, a name given by Gessner and some others, to the bird more usually known by its German name, *ROTHKOPF*.

GALLINULA chalybeata, *flavicauda*, and *erythrogastra*, names by which Gessner, and some others, have called the common *TRINGA*; a bird in which the legs are, at different ages, and in the different sexes, greenish, yellowish, or reddish.

GALLINULA felix, in *Ornithology*, a name given indifferently by many authors to the *GRIVETTA*, and the water-rail; both birds of the moor-hen kind, but smaller than the common moor-hen.

GALLION, or **GALLIEN**, formerly denoted a large vessel, or ship of war, of three or four decks.

GALLIEN is now only used in speaking of the Spanish fleets; the *galien* being a part of the ships employed in the commerce of the West Indies.

The Spaniards send every year two fleets, the one for Mexico, which they call the *FLOTA*; and the other for Peru, which they call the *POINTE*.

GALLIEN, *Manila*, is a ship employed in the trade from Manila to the island of Luconia, the chief of the Philippine islands; to Acapulco on the coast of Mexico. This ship first set from Manila about July, and arrives at Acapulco in December, January, or February following. There is seldom more than one ship employed in this trade at a time; but there are three or four small ships provided to carry on this commerce, one of which is always ready for the sea when the other arrives. The largest of these ships is little less than one of our first rate men of war, and carries twelve hundred men; the others are of the burthen of twelve hundred ton and upwards, and carry from three hundred and fifty to six hundred men, with between fifty and fifty guns. These ships are commissioned and paid by the king of Spain, who pays the officers and crew; and one of the captives is called the general, and carries the royal standard of Spain at the top-gallant-mast-head. The trade from Manila to Acapulco consists of such commodities, collected in China and different parts of India, as are intended to supply the kingdoms of Mexico and Peru. There are, besides, all sorts of Chinese silk and manufactures, particularly silk stockings, of which the annual ship usually carries more than fifty thousand pairs, vast quantities of Indian stuffs, as calicoes, and chams, together with other various articles, as goldsmith work, &c. which is performed at Manila by the Chinese, of whom there are not less than twenty thousand who constantly reside there. However this trade is not open to all the inhabitants of Manila; but is restricted by regulations similar to those of the regular ships from Cadix to the West Indies. The value of this trade is limited by the royal edicts, as it has been fixed by some, to six hundred thousand dollars; but it is reasonable to conclude that the return of it cannot be much more than three millions of dollars. The voyage of the ships employed in this trade is divided into a certain number of bales of the same size, which are distributed among the convents at Manila; but principally to the fathers for the support of their missions; and these convents have a right to embark such a quantity of goods on board the Manila ship, as the language of their bibles amounts to, or to fill the passage to others. This ship, having disposed of its effects at Acapulco, returns for Manila some time in March, where it generally arrives in June; so that the whole voyage takes up near a year. The principal return from Acapulco to Manila is always made in silver, the rest of the cargo being lumberable and consisting of cochineal and sweetmeats, the produce of the American settlements. *Europe's* ordinary wars for the women at Manila, and some Spanish wars, at first and thereby, which are intended for the use of their provision the administration of the sacrament. The *galien* in its return is much less incumbered with her cargo than in her passage thither; and therefore her crew is considerably augmented and her lower tier of guns is mounted, which before was carried in her hold; at least till she came near Cape St. Lucas and California, where she apprehended an enemy. *Antony's Voyage*, chap. 2, p. 225-226.

There are all ships of war, and go on the king's account; but

but they are so loaded and embarrassed with merchandises, that, in case of an attack, they find it difficult to defend themselves.

Inside the king's palace, there are usually twelve or sixteen merchant-ships, called REGISTER-ships, belonging to private persons, who obtain leave for the time, or rather buy it, there being no West India company in Spain.

The *galleons* are loaded at Cadix, from whence they may put out at any time. They were formerly appointed to be out in January, that they might coast along the firm land, and coast about the middle of April to Porto Bello, where, the fair being over, they might take aboard the plate, and be at the Havannah with it about the middle of June, where the New Spain fleet would join them, and they might coast together more safely to Spain. For this purpose, the viceroys of Peru was to take care that the plate should be at Panama by the middle of March; the plate is fifteen days in running from Porto to Azua; eight days generally from thence, by sea, to Calles, and twenty from Calles to Panama, taking in by the way the plate at Pinar and Truxillo. But it has been found by experience, that the month of September is the best time to be in Cadix; they are always ready to sail in the whole voyage. However, when a likelihood of *galleons* go out, they will face *persecute* so till the last are returned. When the *galleons* and five passengers together, they separate about the Antilles islands; the *galleons* for Carthagena and Porto Bello; and the fleet for Vera Cruz. At their return, they rejoin at the Havannah in the life of Cuba.

The loading of the *galleons* is always the richest: an estimate of the yearly returns of cargoes, both of the *flota* and *galleons*, was formerly as follows:

Of gold, the *galam* bring yearly about two or three millions of crowns, and the *flota* about one. Of silver, the *galam* bring eighteen or twenty thousand crowns, and the *flota* ten or twelve. Of precious stones, the *galam* bring as follows: two hundred thousand crowns worth of pearls, two or three hundred thousand crowns of emeralds, and twenty or thirty thousand crowns worth of bezels, amethysts, and rubi stones of less value: the *flota* brings none at all. Of furs, the *galam* bring forty or fifty thousand crowns: the *flota*, none. Of quinquina, the *galam* bring the value of twenty thousand crowns: the *flota*, none. Of skins and leather, the *galam* bring seventy thousand crowns worth: the *flota* much. Of Campechy wood, the *galam* bring forty thousand crowns worth: the *flota*, none. Of skins and leather from Barroo Ayres, the realle-things may bring to two hundred thousand crowns or more each, about a million of crowns, and of indigo, about six hundred thousand crowns.

By a general ordinance in Spain, it has been established that there should be twelve men of war and five tender fitted out annually for the armada of *galions*; eight ships of six hundred tons burthen each; and three tenders, one of a hundred tons, for the island Margatita; and two of eighty each to follow the armada. For the New Spain fleet two ships of six hundred tons each, and two tenders of eighty each; and for the Honduras fleet, two ships of five hundred tons each, and in case no fleet happened to fill any year, three *galions* and a tender should be sent to New Spain for the place.

But the number of *gallois* has been different at different times; it has increased in time of war and diminished in time of peace.

GALLIOT, a small galley or a sort of brigantine, built very lightly, and designed only for chase.

She hath but one mast, and can both sail and row. She usually carries two or three pedreros, and hath sixteen or twenty oars.

GALLITRICHUM, in *Botany*, a name by which several authors call the *hermion satureum*, or garden-chervil.

GALLOGLASSES, a kind of militia or soldiery, in Ireland.

C Camden, in his *Annals of Ireland*, p. 797, relates, that the Irish militia consists of cavalry, or horsemen, called *galloglaigh*, or *galloglaighi*, who use a very sharp sort of hatchet; and infantry, called *deron*.

GALLON, an English measure, for things both liquid and dry, containing two pottles, or four quarts.

The *gallon* always contains eight pints, or four quarts; but these pints and quarts, and consequently the *gallon* itself, are different, according to the quality of the things measured: the wine *gallon*, for instance, contains 231 cubic inches, and holds eight pounds, avoirdupois, of pure water; the beer, and ale *gallon*, contain 282 solid inches, and hold ten pounds, three ounces and a quarter; and the *gallon* for grains, meals, &c. 272 1/2 inches.

and holds nine pounds thirteen ounces of pure water.
See MEASURE.

GALLOON, in *Cosmetics*, a thick, narrow kind of ferrit ribbon, or lace, used to edge or border cloaths. The term is ordinarily understood of that made of wool; sometimes that of thread, or even gold or silver.

GALLOP, in the *Manege*, is the swiftest natural pace of a horse, performed by reaches or leaps; the two fore-feet

being raised almost at the same time; and when these are in the air, and just ready to touch the ground again, the two blood-red are lifted almost at once.

The word is borrowed from the barbarous Latin *inferrus*, or *inferus*, is run some derive it from *subterraneus*, others from the Greek *καταρτις*, or *καταρτις*, is *καταρτις*.

In *galloping*, the horse may lead with which leg he pleases; the most usual way is that with the right, in which case the *gallop* is said to be *left*; but whichsoever it be, the hind-leg of the same side must follow it next, which forms an *arc* of *equal girth*, otherwise the legs are said to be *disordered*, and the *gallop* to be *false*—to remedy which disorder, the rider must flay the horse a little on the hand, and help him on the spur on the contrary side to that on which he is disordered.

However, this rule has not been always strictly observed. For hunting horns have been trained to lead intelligently with both feet, because it has been found that a horse which has never been taught to go on with his right fore leg, has been very apt on one fine day, when he has been fresh and found on the other. In order to make a flop in a going straight forward, the rider should carefully put his horse on the right, without steering or changing the spade, and throw his body back a little to accompany the action, and to relieve the horse's thought. In doing this, he should seize the time of making the flop, keeping the hand and body quite still, exactly when he feels the horse put his feet to the ground, in order that by raising them immediately by the next motion which he makes, he may be upon his hunches. When horses do not put out their strength sufficiently, they should be *patented* with the hand, and then slowly again by turns, and they will thus be compelled to obey the hand.

heel. In the flow gales, as well as in the tugs, it is sometimes necessary to cleave the heels to the work's side, which is called *pinch*; but this should be done in such a manner as not to make the horse abandon himself upon the hand, and care must be taken that he be upon his haunches, and not upon his shoulders; and, therefore, when he is pinched, he should be kept in the hand.

put a horse well together, and make him bring his hinder legs under him, the rider must close his legs upon him, panting them very much back; this will oblige him to slide his legs under him: at the same instant let the hand

be raised a little to support him before, and yielded again immediately. Let him be thus supported, and have to rest again from time to time, till he begins to play around his bayonet, and *gambols* leaping and tumbling down as it were upon them; let the rider then press him well the calves of the legs, and he will thus become con-

and sensible to the touch. If a horse has too fine a mouth, going him upon sloping ground, this will oblige him to lean a little upon the hand, in order the better to put himself upon the haunches; and through fear of hurting his bars, he will be prevented from reaching at

States of the country, furnished the kingdom with their poultry. They were much esteemed, and of a middling size, strong, active, nervous, and hardy.

GALLOWES, an instrument of punishment, whereon persons convicted especially of felony, &c. are executed by hanging.

Among our ancestors it was called *forca*, a *fork*: a name by which it is still denominated abroad, particularly in France and Italy. In this latter country, the reason of the name still subsists, the *gallows* being a real fork driven into the ground, across the legs whereof is laid a beam, to which the rope is tied.

GALLOWES of a *plough*, a name given by our farmers to a part of the common plough, from its resembling a *gallows* made for the execution of malefactors in its form, being composed of three pieces of timber, one placed transversely over the heads of the other two. The *gallows* are a part of the plough-head; they are fixed into the box of the plough, or that part through which the axis of the wheels passes. They make an angle with the box inclining upwards. The upper, or transverse piece, is notched in several places, and serves to sustain the *WILDS*, a pair of irons to which a ring and hooks are fastened, and to these the chains of the barnes, by which the whole plough is drawn along.

In some other parts of England, they call this whole part of the plough, the three pieces being from instead of timber, by the name of the *wilds*; and the *gallows* of the *plough* is then the transverse piece at the top of the *CAWNTAYERS*.

GALLS, or **GALLINUTS**. See **GALL**.

GALLUS. See **COCK**.

GALLUS *gallinarius*, in *Ichthyology*, the name of an East Indian fish, approaching to the nature of the *parus* *Adanson*, and called by the Dutch *snouk*. Its body is thick, and rounded; its fin is free from scales, but is very uneven, full of tubercles, spotted, and variegated with those streaks of a blackish hue; its head is large and thick, and very full of tubercles; its nose large, its eyes red, and its tail obtuse; its belly-fins are red. It is a very well-tasted fish, and much valued there. When first taken out of the water, it makes a very remarkable grunting noise.

GALLUS *marinus*, in *Ichthyology*, a name given by many writers to the fish called in English the *DOBBIE*, and more commonly known in Latin by the name *FORXER*.

GALLUS *marinus* is also a name by which some have called the fish more frequently known by the name of the *ONAGER* *fish*.

GALLY, on *Ship-board*, a place in the cook-room, where the grates are put up, fires lighted, and the victuals boiled and roasted.

GALLY-worm, in *Zoology*, an insect known by most writers under the name *JAUL*. It is a land-insect with a long body, composed of a great number of rings, and furnished with a great number of feet. It is found very frequently in gardens, and when touched, has the power of rolling itself up into a ball.

It is esteemed a valuable medicine in the jaundice, and in supuration of urine.

This animal is very common with us among rubbish, and is by some referred to the scolopendra, but improperly; for though they agree in the great number of legs, ours is a harmless animal, and the scolopendra are mischievous creatures, armed with dangerous forceps. It is supported by Linnæus, that this creature, common with us, would, on distillation, yield the same sort of animal salt that is procured from the ant. The reason of the conjecture is, that the ant and this creature both agree in emitting a sharp and pungent smell on being bruised; but there are not easily procured in plenty enough to make the experiment, as they are not a gregarious insect like the ant. Possibly some more of the insects may be found, on trial, to have the same acid. Phil. Trans. N° 69.

GAMBETTA, in *Ornithology*, the name of a bird somewhat resembling the common redstart. Its head, neck, and breast, are grey, full of brown spots; these are larger on the back, and smaller on the breast and belly, and smallest of all on the throat. Its whole back is of a grey, a little inclining to a reddish brown on the lower part of the back; and on the wings; its belly is white, and its back black. It is common in Italy, and some other places. Aristoteli, de Avib. lib. xi. and xvi.

Mr. Pennant describes one of this species, the *tringa gambetta* of Linnaeus, which was shot on the coast of Lincolnshire, about the size of the green-shank; the head, back, and breast, being of an ash-brown, spotted with dull yellow; the coverts of the wings, scapulars, cinereous, edged with yellow; the primaries dusky; the shaft of the first feather white; belly white; tail dusky bordered with yellow; and legs yellow. *Zoology*, vol. ii. p. 495.

GAMBETON, **GAMBETSON**, **GAMBESIO**, in the *Asian Military Language*, was a kind of coat or doublet, worn under the curial, to make it fit easy, and prevent its hurting the body.

It was made of wool or cotton, quilted between two fluffs; and was likewise called *counter-point*.

Others define the *gambeson* a kind of soft quilted waistcoat, worn under the coat of mail, and hanging down over the thighs.

Pellera ut arith, ut gambesonibus armat.

GAMBOGE is a concrete gummy resinous juice of certain trees growing in Cambodia or Cambolia, and some other parts of the East Indies: it is brought over to us in large cakes or rolls, externally of a brownish yellow, and internally of a deep reddish yellow, or orange colour, changing to a pale bright yellow on being sun-dried. The gummy parts of this juice are so intimately blended with the resinous, that the greatest part of it is soluble either by water or spirit of wine: it is also inflammable, and easily melts with a very gentle heat. If mixed with an equal quantity of salt of tartar, it readily dissolves in common water, in a few hours digestion; this solution, if kept over the fire, soon becomes a sort of smooth glue or jelly; and this, by adding a large quantity of water, is easily reduced into a red clear liquor, in a warm digestion: this liquor, evaporated over a gentle fire, yields a greenish salt, which easily imbibes moisture from the air, if not kept in a glass well stopp'd; and this extract purges in a smaller dose than the gum itself, and yet with less irritation; its taste, however, is extremely acrimonious and fiery, and it must therefore be well digested before it is given. There is, however, another method of giving it, yet more to be recommended than this for general uses: this preparation is as follows: tie up the gum in a piece of linen cloth, and put it into a loaf just drawn from the oven; the loaf must be cut open for this purpose, and afterwards tied close together, and set in some place where it will remain warm four and twenty hours; after this the gum is to be taken out and reduced to powder, and this powder tied up again, and put into another loaf, and so on to the fourth or fifth time, after which it is to be powdered and kept for use. By this easy preparation, this medicine loses its violent operation, both as a purgative and emetic, and may be given with great safety; and the crumb of the first loaf, if eaten, proves purgative. *Mem. Acad. Par. 1701.*

In such hydropic cases as require the stricter cathartics, and in other disorders accompanied with a redundancy of ferrous humours, it is an useful and safe hydragogue; in hot, dry, bilious constitutions, it is never to be administered. In all cases it is safe, on first using it, to vomit as well as purge. The dose is from three or four grains to twelve, or at most fifteen. The emetic power of this medicine is restrained by joining it to mercurius dulcis. The pills of *gamboge* are prepared by mixing equal parts of *gamboge*, mercurius dulcis, aloes, and extract of black hellebore, with a sixteenth of their weight of essential oil of juniper-berries, and making the whole into a mass with syrup of black-thorn. Solutions of *gamboge* in alkalized water, and in delinized alkaline spirits, act only by stool and urine, and much more mildly than the juice in substance. The watery tincture is still milder; but the spirituous tincture operates with extreme irritation both upwards and downwards. *Lewis's Mat. Med.*

Gamboge, dissolved in water, forms a beautiful yellow pigment, and is much used as such by painters. Dr. Lewis says, that it gives a beautiful and durable crimson yellow stain to marble, whether rubbed in substance on the hot stone, or applied, as *Dragon's blood* sometimes is, in form of a spirituous tincture. When it is applied on cold marble, the stone is afterwards heated, to make the colour penetrate. *Neumann's Chem. by Lewis, p. 400, note B.*

GAME, *Indus*, a regular direction, or a spot prescribed and limited by rules. *Games* may be distinguished into those of exercise and address, and those of chance, or hazard. To the first belong *cricket, billiards, chess, bowls, and darts, wrestling, quarts, shooting with bows, &c.* To these also belong the ancient *jeu de torsement*. Under the second come *cards and dice, &c.*

Under *cards*, again, come several subordinate *games*; the principal whereof are *OMBER, PICQUE, EMBLEE, WHIST, &c.*

GAMES, *Indi*, in the plural, were shows, or public representations, used among the ancients on religious, literary, and other solemn occasions.

Such, among the Greeks, were the *OLYMPIC, PYTHIAN, IATHMAN, and NEMEAN games*.

Among the Romans, there were three sorts of *games*; *faeces, ludiarii*, and *inducere*; and *Aulus Gellius* observes a difference,

The next qualification relates to deer and conies only: this forbids a person, not having the licence of a year, or goods of 200*l.* value, from using any gun or bow to kill deer or conies, or from keeping nets or snares, except he hath enclosed grounds, in which the increase of the conies amounts to 200*l.* a year, or be a keeper or warrenor, under the penalty of having his gun, nets, &c. liable to be taken away by any person having lands or hereditaments of 100*l.* a year in fee or for life. 3 Jac. I. cap. 25.

The third of a manor, or one having inheritance of 20*l.* per annum, lives estate of 80*l.* or goods worth 200*l.* or their servants licensed by them, may take pheasants or partridges within their own lands or premises, in the day-time, between Michaelmas and Christmas. 7 Jac. I. cap. 17.

Hawking of pheasants and partridges between the first of July and the last of August is prohibited, under the penalty of 2*l.* for every such hawking, and 20*l.* for every pheasant or partridge destroyed. 7 Jac. cap. 17.

Any man who takes away any of the following deer, without consent of the owner, shall forfeit 20*l.* to be taken by the owner, and shall to the owner, and the other to the informer; or, for want of such distress, shall suffer a year's imprisonment. 13 Car. II.

Words of manor, or other records, that under the degree of a knight, any commission one or more gamekeepers, who may have all hares, dogs, bows, &c. or persons not having estates, in their own or wife's right of 100*l.* per annum freehold, or for term of life or 150*l.* per annum freehold, the twenty-five years or upwards, or not being five and sixths of a quarter, or of higher degree, or owners or keepers of a forest, park, chase, or warren, and destroy, or convert such deer, &c. to the use of the third, 22 and 23 Car. II. cap. 25. For this purpose it has been judged necessary to have a warrant from a justice of peace, after information and oath of the offence first made. This is the last general qualification for killing deer, and that which is now most to be regarded.

If any enter a convey-warren, though not enclosed, and chase or kill conies, he shall forfeit treble damages, and be imprisoned three months; and they that kill conies in the night time upon the borders of warrens, or grounds used for keeping conies, shall be answered at the discretion of the justice of peace, in any sum not exceeding 10*l.* at flat.

He who unlawfully hunts, takes in toils, kills, or takes away any deer, in any forest, chase, park, pasture, or other inclosed ground, or shall be using and assisting therein shall forfeit 20*l.* for unlawfully counting or hunting, though none shall be wounded or taken; and in case any be wounded, or killed, or taken, 20*l.* for every such deer, one third to the poor, one third to the informer, and one third to the owner of the deer, to be levied by distress. 3 Will. and Mary. 5 Geo. I. cap. 15. 9 Geo. cap. 22. and 10 Geo. II. cap. 31. And if a keeper of a forest, &c. be an offender herein, or be aiding therein, he shall forfeit 20*l.* 5 Geo. I. to be levied as above.

In case any hares, partridges, pheasants, hares, hares, or other game shall be found in any offender's house, he shall forfeit 20*l.* nor less than 5*l.* nor more than 20*l.* to be levied by distress, half to the informer, and half to the poor, or, in case thereof, he shall be committed to the house of correction for a space of time not greater than a month, nor less than ten days. And if any person, not qualified by law, shall keep or sell any hares, greyhounds, ferrets, dogs, ferrets, hares, &c. he shall be subject to the same penalties. 2 and 5 Will. cap. 25.

If any hares, chamois, caribou, reindeer, or whatever shall have been kept any hare, pheasant, partridge, hares, dogs, or greyhound, not put in his hands by a person qualified by law, he shall forfeit 20*l.* for every such hare, 20*l.* half to the informer, and half to the poor, to be levied by distress, or, for want thereof, he shall be sent to the house of correction for three months for the first offence, and for every other offence four months. 5 Anne, cap. 14.

If any person, whether he be qualified or not, shall sell, or expose to sale any hare, pheasant, partridge, moor, hares, dogs, or greyhound, he shall be liable to the same penalty. 28 Geo. II. cap. 22.

Persons not qualified, keeping greyhounds, lurchers, ferrets, dogs, or engines to destroy game, and gamekeepers, who, under colour of office, kill and sell game without their master's knowledge, are liable to the like penalty. 5 Anne, cap. 14.

No lord of a manor is to appoint more than one gamekeeper, and his name to be entered with the clerk of the peace, who is to give a certificate thereof; otherwise he is liable to the penalties against biggers. And if any

other gamekeeper, whose name is not so entered, who shall not be otherwise qualified by the laws of this kingdom to kill hares, shall kill, sell, or expose to sale any hare, pheasant, partridge, moor, hares, dogs, or greyhound, on conviction before any justice, and on the oath of one witness, be liable to the same penalty as the first offence, and for every other offence be sent to the house of correction for four months. 5 and 9 Anne, cap. 25.

If any hare, pheasant, &c. be found in the possession of a person not qualified, unless he be entitled to it by some person that is qualified, the same shall be adjudged an offence to be sold. Persons delivering a hare in the night, shall incur the forfeiture of 20*l.* 9 Anne, cap. 25. 28 Geo. II. cap. 22.

Any justice or magistrate, and lord within his manor, may take away such hares, &c. found in the custody of a person not qualified, and any person that shall deliver such hare, &c. in his hands, &c. and shall in three months discover any hare, &c. or deliver to any justice, &c. that hath bought or sold, or offered to buy or sell, or had in his possession any hare, &c. shall be discharged of the penalty annexed to his offence, and receive the same benefit as any other informer. 5 Anne, cap. 14.

No lord of a manor shall appoint a gamekeeper, with power to kill or destroy game, unless he be qualified by the laws of the realm, be truly a freeman of such lord, or be immediately employed to kill game for the sole use of such lord; nor shall any lord appoint a person not qualified to keep any gun, greyhound, &c. and each person so shall be bound to remain in the service of his lord, and recovery of his wages. 3 Geo. I. cap. 15. If any person noted a park, pasture, or other inclosed ground, where deer are usually kept, and unlawfully wound or kill any red or fallow deer, he shall be transferred to the penitentiary for seven years. 3 Geo. I. See also Act 12.

If any person shall by hares, hares, or other nets, drive and take any wild ducks, teal, quail, or any other waterfowl, in any place of resort to which, or in the morning hours, between June 1 and Oct. 1, yearly, he shall, on conviction, forfeit for every such first 20*l.* half to the informer, and half to the poor, or distress, or be committed to the house of correction for a space not exceeding one month, nor less than fourteen days; and the next shall be seized and delivered to the penitentiary. 17 Geo. II. cap. 25. 10 Geo. II. cap. 31. And persons destroying the eggs of any wildfowl, teal, or other waterfowl, from March 1 to June 1, shall be liable to a year's imprisonment, or forfeiture of one penny for every egg. 24 Hen. VIII. cap. 11.

No person shall, in any pasture whatsoever, take, kill, carry, sell, buy, or have in his possession or use, any partridge, between Feb. 12 and Sept. 1, or any pheasant, between Feb. 1 and Oct. 1, yearly, on pain of forfeiture, on conviction by one witness in any of the courts at record at Westminster, 5*l.* for every first hawk, with full oath. 2 Geo. II. cap. 19.

And if any person shall shoot at, kill, or take any dovecot, or pigeon, and be convicted by oath, or, in case of one witness, before one justice, where the offence was committed, or the party apprehended, he shall forfeit 20*l.* to the prosecutor, or be committed to gaol in the house of correction for a time not exceeding three calendar months, nor less than one. 11 Geo. I.

If any person shall knowingly or wilfully kill, take, or destroy, or be in any gun, dog, ferret, net, or other engine, with intent to kill, take, or destroy any hare, pheasant, partridge, moor, hare, or hares, in the night between the hours of sunset at night and six in the morning, from the 21st day of October to the 21st day of February, and between the hours of nine at night and five in the morning, from the 21st day of February to the 21st day of October, or, in the day-time, upon a Sunday or Christmas-day, he shall, on conviction by oath of one witness, before one justice, forfeit for the first offence a sum not exceeding 20*l.* more than 20*l.* for the second offence not more than 20*l.* nor less than 20*l.* and for the third and every subsequent offence 20*l.* each penalty to be levied by distress, and to be paid half to the informer, and half to the poor. In case of refusal of payment of the fine of 20*l.* the offender shall be committed to the house of correction for no less than six, nor more than twelve calendar months, unless such penalty shall be sooner paid; and the offender may be once publicly whipped, if the justice think proper. 1 Geo. III. cap. 25.

No person shall take, destroy, carry, kill, buy, or have in his possession any hares, teal, called black game, between Dec. 10 and Aug. 20, nor any grouse, commonly called red game, between Dec. 10 and Aug. 15, nor any bantard, between March 1 and Sept. 1, in any year, on pain

paid of forfeiting for the first offence any sum not exceeding 20*l.* nor less than 10*l.* and for the second, and every subsequent offence, not exceeding 50*l.* nor less than 20*l.* half to the informer, and half to the poor. 13 Geo. II. cap. 55. See FINEING, HAWKING, HAWKING, &c.

firing 10*l.* or 20*l.* within twenty-four hours, he shall forfeit five times the sum voted, deducting the charges that go to the poor. By several statutes of the reign of king George III. viz. 17 Geo. II. cap. 28. 17 Geo. II. cap. 19. and 18 Geo. II. cap. 54. all private lotteries by tickets, cards, or dice, and particularly the game of *loto*, *hanc*, *acc*, *hearts*, *hazards*, *passage*, *only*, *only*, and all other games with dice, except back-gammon, are prohibited under a penalty of 20*l.* for him that shall erect such lottery, &c. and 5*l.* a time for the players. Public lotteries, unless by a authority of parliament, and all manner of ingenious devices, under the denomination of sales or otherwise, which in the end are equivalent to lotteries, were before prohibited by a great variety of statutes, under heavy pecuniary penalties. 10 and 11 Will. III. cap. 17. 9 Anne, cap. 6. 56. 10 Anne, cap. 26. 4799. 1 Geo. I. cap. 2. 536. 37. 9 Geo. I. cap. 19. 4. 4. 5. 6 Geo. II. cap. 35. 129. 30.

Gaming houses are prohibited under severe penalties by several statutes. No person shall, for his gain or living, keep any common house or place of bowling, corying, cloyds, cays, ball-bow, tennis, dissembling, carding, or any unlawful game, on pain of 40*l.* a day; and every person frequenting such houses and play, and there playing, shall forfeit 6*l.* &c. And justices of the peace, and the head officers of corporations, have power to enter places suspected of unlawful gaming, and to arrest and imprison the keepers and players, till they give security to keep and resort to such houses no longer; and such officers are bound to make search for suspected houses, weekly or monthly, under a forfeiture of 40*l.* a month. Farrier, officers, labourers, servants, &c. are prohibited to play at tables, dice, tennis, cards, bowls, &c. out of Christmas, on pain of 20*l.* and in Christmas only in the houses or presence of their masters. 33 Hen. VIII. cap. 9. Moreover, gaming in public-houses is prohibited under a penalty to the keeper of the house, who knowingly suffers it, of 40*l.* for the first offence, and for every other offence 10*l.* by distress, three fourths of which shall be to the poor, and one fourth to the informer. And any journeyman, labourer, apprentice, or servant, who shall game in such a house, shall forfeit on conviction by confession, on the oath of one witness not more than 20*l.* nor less than 5*l.* at the pleasure of the justice, or be committed to hard labour for a term not exceeding a month. 30 Geo. II. cap. 24. And by 25 Geo. II. cap. 36. any house, or place kept for public dancing, music, or other entertainment in London, or within twenty miles, (except places authorized by letters patent, or licence of the crown, or lord chamberlain,) without licence, granted at the preceding Michaelmas sessions, and signed and sealed by four justices in open court, and of which notice is given over the door or entrance of such licensed place in the following words, viz. Licensed pursuant to act of parliament of the reign of king George the Second, shall be deemed a disorderly house or place, and the keeper thereof shall forfeit 100*l.* with full costs. A constable, on notice given him in writing by any two inhabitants of the parish paying foot and 10*l.* of any person keeping such disorderly house, and on their making oath to such notice, and entering into a recognizance of 120*l.* each to produce evidence of the offence, shall enter into a recognizance of 50*l.* before a justice of the peace, to prosecute such person; and the justice shall issue his warrant for bringing the accused person before him, and bind him over to appear at the next sessions or assizes; if the constable neglect or refuse to comply with such notice, &c. he shall forfeit 10*l.* to each of the said inhabitants; and the constable shall be allowed the reasonable expenses of the prosecution, to be paid by the overseers of the poor, and on conviction of the offender, the overseers shall pay 10*l.* to each of such inhabitants.

The business of chance or hazard, on which the laws of gaming depend, is of mathematical consideration; inasmuch as it admits of more, and less. It is, or is supposed to be, an equality of chance, upon which the gamblers set out: this equality is to be broken in upon in the course of the game by the greater good fortune or address of one of the parties, upon which he comes to have a better chance; so that his share in the deposit, or stake, is now proportionally more or better than at first: this more and less is continually varying, and runs through all the ratios between equality and infinite difference; or from an infinitely small difference till it arrives at an infinitely great one, upon which the game is ended.

The whole game, therefore, with respect to the event or issue thereof, is only a change of the quantity of each person's share, or chance, or of the proportion that two shares bear to each other; which mathematics alone can measure.

Hence several authors have computed the variety of chance in several cases and circumstances that occur in

gaming.

equal or exceed the number of times that the ace is to be thrown, will denote the number of chances whereby two aces may be thrown; so that $a = 1$, and $b = 3$, $a^2 + 2ab + b^2 = 16$, will be $= 14 + 20 + 30 = 74$, and the whole number of chances, viz. $a^3 + 3a^2b + 3ab^2 + b^3 = 1296$, consequently the probability required will be expressed by $\frac{74}{1296}$.

See Case 6. The probability of the contrary will be $\frac{1222}{1296}$ for in the two terms of the fourth power of $a + b$, a^4 and b^4 , a is found only once in the first, and not at all in the second; therefore, these will express the number of chances against throwing two aces, which is $= 500 + 62 = 562$. And the probability of succeeding will be $1 - \frac{562}{1296} = \frac{734}{1296}$ as before. And answer.

fully, the last term of any power $a + b$ being b^n , and the last but one $a b^{n-1}$, is in either of which a enters, it follows that the two last terms of that power express the number of chances that are contrary to the throwing of two aces, in any number of throws denominated by n ; and that the probability of throwing two aces will be $\frac{a^2 b^{n-2} + a b^{n-1}}{a^n + b^n}$. And likewise,

In the three last terms of the power $a + b$, every one of the indices of a will be less than three, and consequently those last terms will show the number of chances that are contrary to the throwing of an ace three times in any number of trials n , and the same rule will hold perpetually. If the chances for failing and happening in any particular trial be respectively represented by a and b , the preceding rules may be applied to the happening or failing of any other kind of events in any number of times.

12. If A lays a wager that a certain event will happen l times in n trials, and B lays to the contrary, and the number of chances of happening and failing in one trial be respectively a and b , the number of chances whereby B may win his wager will be determined by as many of the last terms of the power $a + b$ expanded, as are represented by l . And the number of chances whereby A may be a winner, will be expressed by as many of the first terms of the same power as are equal to $n - l$ being assumed equal to $n - l + 1$, because B , by laying against A 's winning l times, does in effect lay that he will not win above $l - 1$ times; but the whole number of winnings and losses being n , $n - l + 1$, or $n - l + 1$, will be the number of times which B himself undertakes to win.

13. If A and B , being at play, respectively want l and p games of being up, and their respective chances for winning any one game be a and b , raise the binomial $a + b$ to a power whose index is $l + p - 1$, and the number of chances whereby they may respectively win the bet, will be in the same proportion as the sum of so many of the first terms of the power as are expressed by l , to the sum of so many of the last terms as are expressed by p , for when A and B respectively undertake to win l games, and p games, and a represented the whole number of games, in the preceding case, p was $= n - l + 1$; and, therefore, $l + p = n + 1$, and $n + 1 - 1 = n$, which will, consequently, represent the power to which $a + b$ will be raised. E. g. let $l = 3$, $p = 7$, $a = 1$, and $b = 3$, then raise $a + b$ to the power represented by $l + p - 1$, i. e. to the ninth power, and the sum of the first seven terms will be to the sum of the three last, in the proportion of the respective chances whereby A and B may win the bet. The chances of B , or the three last terms, are $1 + 9a^2b + 36ab^2 = 37812500$, which, divided by $a + b = 4$, is 9453125 , gives the fraction $\frac{37812500}{9453125} = \frac{0453125}{154217748}$, expressing the probability of B 's winning; and this fraction, fabricated from unity, or $1 - \frac{0453125}{154217748} = \frac{33554432}{154217748}$, will express the probability of A 's winning; and the odds in favour of A are to the proportion of 33554432 to 0453125 , or nearly as 25 to 1. See Case 10.

Examples often occur, as in this case, in which it is required to find up several terms of a high power of the binomial $a + b$, and to divide their sum by that power; the most convenient method of doing this is to write a and b for a and b , having taken $a = 1$, $b = 3$, and to use a table of LOGARITHMS. Thus, in the preceding example, $a = 1$, $b = 3$, therefore $a + b = 4$, and the quantity $(1 + 9a^2b + 36ab^2)$ becomes $1 + 9 + 36 = 45$, and $\frac{45}{4^8}$ becomes $\frac{45}{65536}$, but the factor $9^7 + 9^6 + 36$ is $=$

$$\frac{25}{9} + \frac{45}{3} + 36 = \frac{484}{9}, \text{ and its logarithm is the logarithm of } 484 - \log. 9 = 1.7306079$$

To which add the log. of a^7 ,

$$\text{or } 7 \times \log. 5 - \log. 3 = 3.5529420$$

$$\text{And from the sum} = 3.2835439$$

$$\text{Subtract the log. of } (1 + 9)$$

$$\text{or } 0 \times \log. 8 - \log. 3 = 3.8337183$$

$$\text{And the remainder} = 1.4498255$$

will be the logarithm of B 's chances, viz. 0.2817251 ,

and the complement of this to unity, or 0.7182749 , will be the chance of A . See another method of reducing ratios in large numbers to their least exact terms, under RATIO.

The following TABLE shows the odds of winning, when the number of games wanting does not exceed six, and the skill of the contenders is equal.

Games wanting.	Odds of winning.	Games wanting.	Odds of winning.	Games wanting.	Odds of winning.
1, 2	3, 1165	1, 1165	355	0, 448	
1, 3	7, 1164	2, 265	159	2, 37	
1, 4	15, 1165	5, 57	45	15, 93	
1, 5	31, 1165	13, 9	46	38, 10	
1, 6	63, 1164	42, 23	5, 6	0, 8	

14. To find the probability of throwing one ace, and no more, with four dice at one throw. From the number of chances whereby one ace or more may be thrown, subtract the number of chances whereby two aces or more may be thrown, and the remainder will be the number of chances for throwing one ace, and no more. Having raised the binomial $a + b$ to its fourth power, which is $a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4$, it is evident, that the four last terms express the number of chances for throwing one ace or more, and the three first terms express the number of chances for throwing two aces or more; and, therefore, the single term a^4 expresses the number of chances for throwing one ace and no more; and the probability required will be $\frac{a^4}{a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4} = \frac{1}{1296} = \frac{1}{324}$.

See Case 7. When it is required to assign the chances for throwing any number of aces, and no more than that number, one single term of the power $a + b$ will always answer the question; and this term may be expeditiously found, supposing a to be the number of dice, and l the precise number of aces to be thrown, when l is less than a , and by writing as many terms of the series $\frac{n}{1}, \frac{n-1}{2}, \frac{n-2}{3}, \dots$, as there are units in l ; and when l is greater

than $\frac{1}{2}n$, by writing as many of them as there are units in $\frac{1}{2}n - l$, then multiplying all those terms together, and multiplying the product by a^{n-l} , and this last product will exhibit the term expressing the number of chances required. E. g. Let $l = 3$, and $n = 10$; since l is less than $\frac{1}{2}n$, take three terms of the series, which will be $\frac{10}{1}, \frac{9}{2}, \frac{8}{3}$, their product will be 120 ;

if $l = 4$, a being $= 1$, $b = 3$, &c. will be 6042609 ; and $6042609 \times 120 = 725113080$, which expresses the number of chances required. Divide this by $a^4 R^6 = 1000000000$, and the quotient 0.725113080 , will express the probability of throwing precisely three aces with ten dice. Subtract this quotient from unity, and the remainder 0.274886920 will express the probability of the contrary; and the odds against throwing precisely three aces with ten dice, are 0.274886920 to 0.725113080 , or nearly 5 to 3.

Having thus given as compendious a view as possible of the principles and rules of GAMING, from Mr. De Moivre's Introduction, we shall select a few problems, for the farther illustration and exercise of these principles and rules.

Prob. I. If A and B play with single balls, and A can give B two games out of three, when in the progress of their skill, a is to the odds, that B may get any one game off a . Let the proportion of odds be as n to 1; now since A can give B two games out of three, A may, upon an equality of play, undertake to win three games together; but the probability of his winning the first time is $\frac{n}{n+1}$, and the probability of his winning three

times together is $\frac{n}{n+1} \times \frac{n}{n+1} \times \frac{n}{n+1} = \frac{n^3}{(n+1)^3}$. See EXERCITATION. But, as A and B are supposed to play on equal

lacy must have been very far stretched to make the resemblance.

GAMMADIUM, a triangular vestment used in the primitive church.

GAMMER, *see* the article **GIMMER**.

GAMMONING, on *ship-board*, are several turns of rope taken round the bowsprit, and secured through holes in the knees of the mast, for the greater security of the bowsprit.

GAMMUT, **GAMUT**, or **GAM-ut**, in *Music*, a scale, wherein we may learn to sound the musical notes, as *ut, re, mi, fa, sol, la*, in their several orders, and dispositions.

The invention of this scale is owing to Guido Aretin, monk of Arezzo, in Tuscany, about the year 1009; though it is not so properly an invention, as an improvement on the **DIAGRAM**, or scale, of the ancients.

The *gamut* is also called the **HARMONICAL HAND**, because Guido first made use of the figure of the hand to arrange his notes on.

Finding the Greek diagram of too small extent, Guido added five more chords, or notes, to it; one below the prothomachoron, or gravest note, of the ancients; and four above the note hypochoron, or acutest.

The fifth he called *hyperprothomachoron*, and denoted it by the letter *G*, or rather the Greek *Gamma*, which note being at the head of the scale, occasioned the whole scale to be called by the barbarous name *gamut*, or *gammut*.

Some say, Guido's intention, in calling his first note *G*, *gamma*, was to show that the Greeks were the inventors of music; others, that he meant hereby to record himself, this being the first letter of his own name.

Guido's scale is divided into three series, or columns; the first called *maior*, or flat; the second *cantus*; and the third *durum*, or sharp; as represented in the scheme *Tab. Music. fig. 4*.

But, since his time, some alterations have been made therein. The use of this scale is, to make the passages, and transpositions, from *B* *mollis*, or *B* *durum*, by means of the tones and semitones. The series of *B* natural, standing between the other two, communicates with both; so that, to transpose the chords of the scale by these syllables, if we would have the semitones in their natural place, viz. *a, c, e, g*, then we apply *re* to *a*; and after *re* we go into the series of *B* natural, at *fa*; and after *a* if we return to the former at *re*, and so on; or we may begin at *re* in *a*, and pass into the first series at *re*, and then back to the other at *fa*; by which means the one transition is a semitone; viz. *la, fa*; and the other a tone *la, mi*. To follow the order of *B* *mollis*, we may begin with *mi* in *a*, or *fa*, and make transitions after the same manner.

Hence came the barbarous names of *gamut, ara, lmi, &c.* But it is a perplexed work, with so many different syllables applied to every chord, to mark the places of the semitones; which the simple letters *a, b, c, &c.* do as well, and with more ease.

Several alterations have since been made in the *gamut*. M. le Maire, particularly, has added a seventh note; viz. *fi*, and the English usually throw out both *re* and *fa*, and make the other five serve for all; as will be shewn under the article **DOCTRINA**.

GAMMUT, or **GAMUT**, is also the first or gravest note in the modern scale of music; the reason of which is shewn under the preceding article.

GANACHES, in the *Monoxy*, are the two bones, one on each side of the hinder part of the head, opposite to the rock, or axis of the head, which form the lower jaw, and give it motion. It is in this place that the glands or kernels of the tongue, and the glands, are placed.

GANCHE, *Fr.* derived from the Italian *ganca*, *best*, a kind of *GALLOWS* or gibbet used for the punishment of criminals in Turkey. The executioner takes the condemned by means of a pulley, and suddenly slackening the rope, lets them fall on hooks of iron, which entangle and rend their bodies; in this condition they are left to die, and some have been known to languish for two or three days.

GANG, in the *Sea Language*, signifies a crew.

To man a boat is called, to put a *gang* of men (which is a company) into her; they are commonly called the *scholar's gang*, who have the charge of her.

GANG-FISH, a name given by some authors to a small fish caught in the German lakes, and sent in pickle into many parts of the world. The more usual name of this fish among writers is **LABARETUS**.

The *gang-fish* is a species of the **CONGRIUS**, distinguished by Arted by the name of the *evergreen*, with the upper jaw longest and flat, and with fourteen rays in the back fin.

GANG, *see* **See** **Oz**.

GANG-WAY is applied to all the several entrances, ways, or passages, from one part of the ship to the other. Whatever is put in any of these passages is said to be laid or put in the *gang way*. See *Tab. Ship. fig. 2. n. 22, 23, 24*.

GANG-WAY also denotes that part of a ship's side, both within and without, by which the passengers enter and depart; it is for this purpose provided with a sufficient number of steps, or *boards*, nailed upon the ship's side, nearly as low as the surface of the water; and sometimes furnished with a ladder, whose lower end projects from the ship's side, being fixed in this position by iron bolts.

GANG-WATER. See **WATER-CURR**.

GANGLES, or **GANGLES**, a name given by some to the *ligati arterie*, or eagle-veins.

GANGLIO, **GANGLION**, in Surgery, a small, hard, knotty tumor, generally moveable, and usually formed in the tendons or ligaments, in the external or internal part of the carpus, without any discolouring of the skin, or any kind of pain.

The word is Greek, *ganglion*, which signifies the fund. The tumor, when on the nerves, tendons, articulations, or any of the membranous parts, remains in almost every other situation called *ganglion*.

The cause of the *ganglion* is a too great distension of the parts of the parts, or too great compression, or a laceration thereof; any of these occasions the nutritious juice to be there stopped, and retained; and even to canker, coagulate, and harden into a tumor. The same effect is sometimes also produced by a lesser hard labour, or the like. Most authors hold the cause of the *ganglion* to be a very heavy accidental injury.

Authors in general who have treated of the *ganglion*, have referred it to the class of encysted tumors, supposing it to be enclosed in a membranous sack, in the manner of the aneurismous and fluctuant encysted tumors. Mr. Eller, in the memoirs of the Berlin Academy, gives a very different account of this tumor; he observes, that very bad symptoms often succeeded the extracting the *ganglion*, in the way of the common encysted tumors, by the knife, and thence concluded, that they must be of a different nature and origin from the common tumors. The matter contained in the *ganglion* is usually found to be of a gelatinous texture, like the jelly of hamlets; and of no bad smell, or sharp taste, and the membrane which contains it always contracts itself to the base into a kind of neck, and is there minutely joined to, and united with the tendon on which it is placed. The appearance of the *ganglion*, however, in the place where the *ganglion* adheres, never appears variated, nor any way different from other parts of it. Memoirs of Berlin, ann. 1718, p. 129.

In order to understand rightly the origin of the *ganglion* we are to consider, that every fibre of the muscle to which the tendon is annexed, and of whose fibres it indeed is only an elongation in a more straightened form, is, while in the muscle, covered with a delicate fine membrane, which leaves it as soon as it leaves the muscle to enter the composition of the tendon; and that all these membranes together form the general covering of the tendon, which is itself in the joining of that part to the bone. This membrane could be rather an inconvenience than an useful covering to the tendon, if it did not separate a limpid and viscous juice, which covers the whole surface of the tendon, and facilitates its common motion. Anatomists in general have neglected to enquire into the nature and use of this membrane which covers the tendon, and therefore have mistaken the origin of the *ganglion*, which is not to be understood without this previous knowledge of the part to which it is wholly owing.

When this membrane suffers with the tendon any external violence from blows, or violent exertions, it external bursts in some parts; and internally follows, that the liquor it before contained must escape through the aperture, and it after this naturally lodges itself in the tunica adipsa of the fily; and as the liquor by degrees increases in quantity, this tunica, or membrane, forms a part of a sack for the reception of it. As the viscous liquor continues to be voided through the aperture, the more sensible parts of it by degrees escape, and the remainder forms the viscous and tough matter, which is found in opening the *ganglion*. In some cases, where the rupture of the membrane has been incomplete, the surface of it stays and forms the covering of the swelling; and in this case represents the aneurism in an artery.

The *ganglion* is sometimes removed, and relieved by more dry friction, long continued; and sometimes by friction with Oil of some kind to apply a plant of lead, anointed with mercury; others use *gum ammoniac*, or the emulsion of yolk, with mercury. If these do not succeed, recourse is had to section.

Mr. Sharp has frequently succeeded by making an incision through the whole length of the ganglion, and at the same time dividing the ligament of the wrist, and afterwards dressing as in common wounds. Mr. Warren gives two instances of his effectually extirpating them: he recommends cutting away part of the cyst, and then digesting the rest away.

GANGLION, in *Anatomy*, denotes a tumor or knot frequently found in the course of the nerves: for wherever any nerve sends out a branch, or receives one from another, or where two nerves join together there is generally a ganglion, or knot, as may be seen at the beginning of all the nerves of the medulla spinalis, and in many other parts of the body. The ganglia of the intercostal nerves, first discovered by Vesalius, are oblong and very hard bodies; and their uses have not yet been satisfactorily ascertained. M. Lancisi, who has paid particular attention to this subject, supposes that they are useful for power, and capable of distention and contraction; and intended to impel and accelerate the nervous fluid with such additional force, as it conceives to be necessary for producing motion in muscles subject to the will. In order to furnish an idea of the structure of other ganglia, he has particularly described and delineated that of the first cervical ganglion. However, Haller, and other eminent anatomists, have not been able to discover this muscular apparatus in the first cervical ganglion. Besides, ganglia, instead of being intrinsically subservient to the will, are almost peculiar to nerves distributed to parts, whose motions are altogether involuntary. The office of ganglia has been conjectured, both by Lancisi and Willoughby, to be analogous to that of the brain, and, therefore, they have considered them as a kind of subsidiary brain, formed for impelling motion in the animal spirits. Ganglia are formed generally on nervous cords resulting from the union of several distinct nerves; they abound with blood-vessels, and commonly exceed in bulk that of all the nerves and vessels which seem to compose them; and hence Morgagni and others have concluded, that in ganglia the different nervous filaments are very intimately mixed, and form a nervous organization, or modification of the medullary substance, so as to form new animal spirits, or alter the direction of those already brought thither. Dr. J. Halliwell, of Kiddleminster, has not long since published observations and conjectures on the structure and uses of the ganglia of the nerves. With regard to their structure, he considers them as little brains, or germs, of the nerves, detached from them, consisting of a mixture of cortical and nervous medullary substance, nourished by several small blood-vessels, in which various nervous filaments are collected, and here losing their rectilinear parallel direction, so that a new nervous organization probably takes place in them. As to their use, he supposes that they are instruments, by which the motion of the heart and intestines are, from the earliest to the latest periods of animal life, rendered uniformly involuntary; or, that they are the immediate origins of the nerves transmitted to organs moved involuntarily, and that they serve to check or restrain our volitions from extending to them. They are analogous to the brain in their office, and, being subordinate springs, or reservoirs of nervous power, seem capable of dispensing it, long after all communication with the brain is cut off. From these ganglia, as subordinate brains, the vital organs derive their nervous power, and continue to move during sleep; and to the same cause, as well as to its greater irritability, the motion of the heart, continued longer than that of the voluntary muscles in perfect apoplexy, is ascribed; and to the same cause, he apprehends, it is also owing, that the heart continues to move even after the spinal marrow and the medullae in their descent along the neck are cut through, so that animals have sometimes survived this experiment for thirty hours. See Phil. Trans. vol. liv. p. 177. Art. 33. and vol. lvi. or Essay on the Use of the Ganglia of the Nerves, 1771.

GANGRENE, GANGRENA, in *Surgery*, is a dangerous degree of inflammation, wherein the parts affected begin to corrupt and putrefy; or a mortification, in its incipient state, while yet the part retains some sense of pain, and a share of the natural heat. By which this disease is distinguished from a *phlegmon*, or thorough mortification, where there is no sense or warmth left.

The word is Greek, *τῆ γὰν*, derived, by some authors, from the Paphlagonian *ganga*, a goat; it being the character of a goat to break the graft all round, without diffusing its place. It is *γὰν*, perhaps, to derive it from the Greek verb *γίγναι*, *gignai*, *minuere*, *diminui*, *I cut, diminish*.

The *gangrene* is a disease chiefly affecting the skin and fat, which it corrupts, consumes, and turns black; and

by degrees spreads and fuses the adjoining parts; and issues in a sphacelus, which is never cured without amputation.

It arises from a stoppage, or interception, of the circulatory motion of the blood; which, by this means, fails to furnish the part with the nutritious and spirituous juices necessary to preserve its warmth and life.

This interception of circulation, which is the proximate cause of the *gangrene*, is itself occasioned divers ways; as by large tumors, erysipelas, great inflammations, violent cold, tight bandages or compresses, sudden fluxions of some malignant humors, bites of venomous beasts, fractures, wounds, and ulcers ill managed, &c. It is distinguished by the colour of the flesh, which first turns pale, then dusky, or *livid*; and by its growing loose, and flabby, after being vehemently tense, which it was before. In the progress of the disease the part diffuses a fetid, discoloured water, and emits a cadaverous smell.

Upon the first seizure the skin turns pale; afterwards it becomes livid; vesications arise, and the colour, at length, changed to black; the flesh becomes cold, faint, and numb; then swells, and soon becomes infarcted; the heat and pulsation of the part being likewise diminished. Thus.

If, in a large wound, the tumor of the lips does not suppurate, nor any flux of matter, or inflammation, arise; if the lips do not swell, or, after swelling, grow lax and flaccid again on a sudden, it is reckoned a sure sign of an approaching *gangrene*.

When a *gangrene* proceeds from extreme cold, the part affected is first numbness, or seized with a pricking pain; this is followed by a redness, which gradually changes to black.

When a tight bandage is the cause, a discolority of the part is joined to the insensibility thereof: when the furver, it often begins in the great toe, and appears in form of a blackish spot; which turns to a dry crust, succeeded by a fluxor of the part, &c. When the bite of a venomous creature is the cause, a continual fever attends, &c. and pain is felt in the part; which usually brings on a lyncope, or delirium; and pustules arise about the bite.

By the microscope a *gangrene* has been discovered to contain an infinite number of little worms, impugnered in the morbid flesh; and which continually producing new broods, swarm, and over-run the adjacent parts.

To stop the progress of the *gangrene*, physicians prescribe, internally, sudorifics and alexipharmics; externally, decoctions of quicklime, either simple, or with the addition of sulphur, mercurius dulcis, and spirit of wine camphorated.

When a *gangrene* seizes a part, the great care to be taken is to prevent, if possible, its terminating in a sphacelus. In strong habits it is always proper in this case, first to bleed largely, and repeat as occasion shall require; and it is a most necessary step in their cases, to be very careful in the beginning, to remove all violent external causes of inflammation; as too tight a bandage in wounds and fractures, all foreign bodies, which are accidentally lodged in the parts, as thorns, splinters, needles, and the like; and all improper external applications, such as oiled plasters, with cooling and astringent things; and especially in old or weak people, to keep up the falling strength by such diet as afford good and suitable juices for nourishment. If the patient is weak, and in years, and naturally of a cold habit; especially if he has lost much blood, and abounds in crassities, the most suitable diet for him will be soup and broth, made of chicken, or meat, with mace and other spices boiled in them; also draughts of cordial liquors, with yolks of eggs, cinnamon and sugar; eggs themselves poached and eaten soft; strong jellies of calves feet, hartshorn, and other things; and old and rich wines; or where the patient's circumstances will not afford these, and nothing particular forbids the use of malt liquors, fine ale not too stale may serve very properly.

With respect to medicines, the proper ones are the cordial thinctures, waters, and electuaries, as the confection of alexemes with spices and other cordial ingredients mixed in it; and teas, made of sage, fennel, and the like herbs, with the spices, or a few shavings of saffron, or yellow saunders; for by these means, the stagnating blood will be greatly relieved and attenuated, and its food and healthy parts will be retained in a due circulation, and its noxious ones discharged and dissipated: it is also of some service in these cases frequently to apply a sponge wet in Hungary water to the nose, or to bind to the wrists, or temporal arteries: the crumb of rye-bread, mixed with powdered cloves, and steeped in strong vinegar, and afterwards made up into a ball, and held frequently to the nose, are also of no little service.

For patients who are of a more warm, sanguine, and bilious habit, fops and decoctions mixed with the acid juices of lemon, or other vegetable acid, are very proper strengtheners, as is barley gruel, mixed with syrup of lemon, or milder rice, or with jelly of currants, to be taken daily for the common drink. But in these cases, when the heat is small, and the patient weak, or before accustomed to wine, it may be allowable to mix a little wine with the gruel. Rhubarb is of all wines the most proper on this occasion, and a glass of that, or if necessary of a richer wine, may be given at proper intervals.

The temperate or cooling medicines, commonly given in fevers, may still be administered very properly in these cases, but above all others, the bark is generally esteemed the great internal remedy in this disorder. To these must be added, the surgeon's utmost attention in the discharging the stagnating and corrupted blood from the parts, as soon as possible, and to prevent the neighbouring parts from being affected thereby, the principal method of doing this is, while the proper internal medicines are given, to make scarifications a circumscribed band direct upon the parts affected, with the folios; these incisions are to be made all lengthwise, and very numerous on the part; and are to be covered to a sufficient depth, that not only the stagnating blood may be by that means discharged; but free way may be made by these openings, for the ingress of the medicinal applications. And lastly, disincision, balsam, and stimulating fomentations and cataplasms are to be with great care applied to the affected parts, and frequently renewed. A very excellent fomentation on these occasions is made by mixing with a pint of lime water, three ounces of camphorated spirit of wine, with half an ounce of spirit of sal ammoniac, or of spirit of wine, with myrrh, aloes, and taffia infused in it, or spirit of wine camphorated, with a small quantity of Venice treacle, and castor permeat. A decoction of rue, wormwood, southernwood, and camomile flowers also, with an admixture of four ounces of Venice treacle, and two ounces of Castile soap, and half an ounce of tallow to the quart makes a very valuable fomentation; this should be applied for several times in a day, by means of doubled linen or woollen cloths dipped in it, and a lasting warmth may often be forcibly kept, by means of a brick made hot by boiling water, and applied afterwards, wrapped up in a linen cloth.

The poor may find a cheap domestic remedy in the pickle of cabbage, or in horle or cow dung, boiled in vinegar, or wine if that can be had; these should be applied warm, on linen or woollen cloths, and it is much better to keep them hot, by means of a hot brick or tile, than to be frequently opening and exposing the part to the air to renew them. A very efficacious fomentation for a gangrene may be made of scordium, wormwood, and southernwood, either separate or mixed and boiled in sea-water, or salt water, or vinegar, which should be applied hot several times a day.

The more desperate a gangrene is, and the nearer it approaches to a phlegmon, the longer and deeper the scarifications must be made; they may now also be on the legs, arms, &c. be made transversely, as well as longitudinally, down to the quick; and afterwards the injured parts are to be well rubbed and wetted with warm and stimulating medicines; and afterwards a penetrating and sufficient cataplasm is to be applied, that the blood in the vital parts may be restored as much as possible to its free and proper motion. A proper cataplasm for this purpose may be made of a few handfuls of scordium, wormwood, feverfew, mallows, mint, and southernwood, boiled in oxycrate to the consistence of a cataplasm, and poultice, with half an ounce of sal ammoniac, and two ounces of linseed meal, with half an ounce of the infused oils of rue or camomile added afterwards to it, before this cataplasm is applied to the part, it is always proper to mix with it a little Venice treacle, or else spirit of wine camphorated, to increase its virtue.

These applications are best renewed about three times a day if they are often, they expose the parts too much to injuries from the external air by so frequent uncovering them; it more seldom, it is possible changes may happen between, with which the surgeon ought to have been timely acquainted. Care however must be taken, either by hot bricks, or some like means, to keep the applications warm all the time they are on, for when suffered to cool upon the part, they are not only useless but very harmful. *Hist. Surgery*, p. 415.

Dr. Le Cat in his letter concerning the cure of dry gangrene, observes, that the cause of these is the want of a flow of the arterial blood and spirits into the part affected, and therefore that the operation of scarification is not only useless, but pernicious; because you thus increase the irritation of the solids, the constriction of the vessels, the

want of fluids and the exsiccation, and hasten death. The general indication which this disorder shews is to loosen and relax the vessels, and to draw thicker the humors by topics, whilst all internal remedies should be given that are capable of loosening the blood and the spirits from the centre to the circumference; and if this method fails, amputation can be of no use, but death is inevitable. As this disorder, he says, arises from internal causes, its cure should be chiefly attempted by internal remedies, and he accordingly administers venereal, diaphoretic, and such medicines as are capable of reviving the drooping spirits and quickening the circulation even to the extremities; to which should also be added medicines adapted to the particular habit of each patient, which may have contributed to have brought on this particular species of gangrene. At the same time emollient, attractive, external remedies, moderately warmed with spices, applied to the part, concur to the same intention, by facilitating the flow of blood and spirits; but spirituous and aqueous topics, impregnated with volatile, and charged with salina, active, and vivaciously stimulating particles, and others in use in ordinary gangrenes, are to be avoided like deadly poisons. On the contrary, in humi gangrenes, it is chiefly the return of the blood which is hindered, and thereby the fluids are accumulated, that swell and extend the diseased part; and this distention, which characterizes the humi gangrene, shews the necessity of scarifications and excoarations after which stimulating topics should be applied. See the several cases in which this method has proved successful in the Phil. Trans. vol. xvi. art. 16.

Hellioe prescribes the following, as the most efficacious remedy known for gangrenes; viz. quinquina, dissolved in double the quantity of spirit of wine, or aqua fortis, a linen cloth being dipped therein, and applied to the gangrenous part. This alone, he asserts, was sufficient. If the gangrene be occasioned by an intrinsic frost, snow-water, or a linen cloth dipped in cold water, and applied to the part affected, Boerhaave directs as the best cure. If the gangrene proceed to an inter-sphaculation, and be seated in any of the limbs or extreme parts, recourse must be had to the operation of amputation.

GANGRINOS, in the *Medica Mores* of the ancients, a word used for follicle itch; Myrcellus plainly refers it to this sense, and Fuchsius explains it by follicle itch, called by the barbarous authors *lat. genus*.

GANGUE, *Germ.* denotes the *MATRIX* of *ores*.

GANGYA, in the *Matris Medus*, a name by which some authors call the testum, or oily purging grain.

GANIMEDES, in *Chemistry*, a name given by some to white sulphur, raised by frequent sublimation; these affected writers gave it this name from its being elevated by fire in the process, as Ganymede is said by the poets among the ancients to have been taken up from the earth, and raised to heaven.

GANNANAPERIDE, in *Botany*, a name by which some authors have called the tree which produces the famous Jesuit bark. See *CONTOX Peruviana*.

GANNET, in *Ornithology*, the name used in Cornwall, and some other parts of England, for the *Pelecanus Rajanus* of Linnaeus, or the *Seland Gannet*. Mr. Ray supposed the Cornish gannet to be a species of large gull; and he was led into this mistake by never having an opportunity of seeing the bird, except flying; and in the air it has the appearance of a gull. On this supposition he gave it the title of *istactura*, a name borrowed from Aristotle, and which admirably expresses the rapid descent of this bird on its prey. Pennant.

GANTLET, or GAUNTLET, a large, strong glove, made to cover the arm, or hand, of a cavalier, armed at all points.

The word is derived of the French *gantlet*; and that from *gant* or *gant*, *gloves*.

The *gantlet* was of iron, and the fingers plated. The cast and *gantlets* were always borne in the ancient marches in ceremony. *Gauntlets* were not introduced till about the thirteenth century.

The *gantlet* was frequently thrown, like the glove, by way of challenge.

GANTLET, in *Surgery*, is a kind of *bandage* for the hand, being a swathe, four or five yards long, wherewith they wrap up the hand, and all the fingers, one after another.

GANTLOPE, a military punishment. See *Military EXECUTION*.

GANTLOPE, or GAUNTLOPE, vulgarly pronounced *gantle*, is a punishment for felony, or some other heinous offence, in a ship of war. For this purpose, the whole ship's crew is disposed in two rows, standing face to face on both sides of the deck, so as to form a lane, whereby to go forward on one side, and return aft on the other; each person being furnished with a small twisted cord, called

called a knittle, having two or three knots upon it. The delinquent is then dropped, naked above the waist, and ordered to pass forward between the two rows of men, and, as on the other side a certain number of men, rarely exceeding three, during which every person gives him a stripe as he runs along. This punishment, which is called *running the gauntlet*, is seldom inflicted except for such crimes as will naturally excite a general animosity among the townsmen.

GANYMEDE, *Ganymede*, a term lately come in use to express a catamite, or harlot. See **SODOMY**. The expression takes its rise from a young beautiful Trojan shepherd, thus called, whom Jupiter ravished, or carried off, by his eagle, or rather by himself, under the figure of an eagle, as he was hunting upon mount Ida; and made him his cup-bearer, in the place of Hebe; who, having made a false step, and spilt her liquor, was turned out of that office.

Some say, that the Jupiter who ravished *Ganymede* was Tantalus, king of Phrygia; the eagle expressed the swift and wherewith he was carried off.

The statue of *Ganymede* was transported from Greece to Rome, and set up in the temple of Peace; and to this festival refers, when he says,

Nonne indepropterea sumus, hic Ganymedem hic facis.

GAOL, a prison, or place of legal confinement. The word is formed of the French *galer*; and that of the barbarous Latin *galo, galo, galo*, a *galo*, whence the Picards still call a bird-cage *galo*. The goaler, goaler, was called *galerius*, and *galerius*. Sculget derives the word *galer* from *januarius*. And some Latin authors call him *communiarius*, because he keeps a register, or list, of all those under his custody.

Every county hath two *gaols* one for debtors, which may be any house where the sheriff pleases; the other for the peace and matters of the crown, which is the county *gaol*.

If a *gaol* be out of repair, insufficient, &c. the justices of the peace in the quarter sessions may agree with workmen for rebuilding, or repairing it; and by warrant under their hands and seals, order the sum agreed upon to be levied upon the several hundred and divisions in the county, by a proportionate rate. 12 Geo. II. cap. 19. See **PARISH-STEERING**.

GAOL delivery. See **JUSTICE**.

GAOLER, is the master of a prison; one that hath the custody of the place where prisoners are kept. Sheriffs must make such *gaolers* for whom they will answer: but if there is a default in the *gaoler*, action lies against him for an escape, &c. 2 Inst. 591. In common cases the sheriff or *gaoler* are chargeable at the discretion of the party; though the sheriff is most usually charged. Wood's Inst. 26.

By 8 and 9 W. III. cap. 27. marshal and warden taking any reward to connive at prisoners escape, forfeit coat and his said office, and is for ever after incapable of holding such office. The office of marshal of the king's bench, and warden of the Fleet shall be executed by those who have the inheritance of the said prison, or their deputies, &c. By 3 Geo. I. cap. 15. no one shall purchase the office of *gaoler*, or any other office pertaining to the high sheriff, under pain of *scout*.

Where a *gaol* is broken by thieves, the *gaoler* is answerable not; if it be broken by enemies. 3 Inst. 52. It is enacted by 22 & 23 Car. II. cap. 20. that the rites of fees and government of prisons be signed by the lord chief justices, &c. and hung up in every *gaol*, fairly written; and also, that felons and prisoners for debt shall not be lodged together. No fees shall be taken by *gaolers* of prisoners, but such as are allowed by law; and the judges, &c. are to settle the same; also the judges may determine petitions against the exactions of *gaolers*, bailiffs, &c. 2 Geo. II. cap. 22. 18 Geo. II. cap. 13.

The shafts of *gaolers* and sheriff's officers towards the unfortunate persons in their custody, are well restrained and guarded against by statute 22 Geo. II. cap. 28.

Gaolers are not justified by law in fettering a prisoner, unless he is unruly, or has attempted an escape. 2 Inst. 381. 3 Inst. 34. The humane language of our ancient laws is in *Caesides sumus*. *Ab* *conspiratione* *non* *agunt*, *ne* *en* *in* *carcerem* *sed* *in* *cella* *tenentur*, *patitur* *et* *adhibere* *publice* *debet* *exequantur*. Hist. lib. 1. cap. 26.

GAOL FEES. See **HOSPITAL FEES**.

GAONS, a certain order of Jewish doctors, who appeared in the East, after the closing of the Talmud. The word *gaon* signifies excellent, sublime, as in the divinity schools we formerly had irreproachable, sublime, resolute, angelic, and subtle doctors. The Gaon succeeded the rabbis, or Opinions, about the beginning of the sixth century. Chanon Meuchia was the best, and first of the excellent; he instituted the academy of Pumbedita, which had been shut up for the space of thirty years.

GARAB, and **AGGARAB**, names given by Arizena to the *scabiosa*, or wild rose.

GARAGAY, in Ornithology, the name of a rapacious bird of Mexico, of the size of our kite; its head and the tips of its wings are white; it makes but short flights; it is very fond of the eggs of tortoises and crocodiles, and hunts the places where they have buried them in the sand.

GARATRONIUM, in Natural History, the name of a foetid body, commonly supposed the same with the bolonites, but very improperly; the only full account of it is that of Ferrante Imperato, who tells us, that it is a purple stone with variegations of a gold yellow, disposed in the manner of the veins of many sorts of marble; and that the Persians, and many of the eastern people, cut it into the handles of their livers. It appears by this description to be a kind of Jasper; and is very improperly confounded with the bolonites, a small stone fit only to be worn in rings.

GARB, a name given by the Moors to an African species of willow.

GARBE, in Heraldry, a representation of a sheaf of corn, or other grain; sometimes borne in coat-armour, to signify summer, or the month of August; as the bunch of grapes denotes autumn.

GARBLER of spics, an officer of great antiquity in the city of London, who is empowered to enter any shop, warehouse, &c. to view and search drags, &c. and to forbid and cleanse them.

GARBLES, the dail, foil, or filth, severed from good spice, drugs, &c.

GARBLING of spices, drugs, &c. is the cleansing it from the dross and duff, mixed therewith, and severing the good from the bad.

The word comes from the Italian, *garbilleri*, to pick.

GARKING of laws, &c. is the sorting or calling out the good from the bad.

GARBOARD-plate, in a Ship, is the first beam next to the keel.

GARBOARD-plank, in a Ship, the first plank fastened on the keel.

GARCINIA, in Botany. See **MANGOSTEAN**.

GARCON, or **GARBOON**, a French term, literally signifying a boy, or male child, any time before his marriage.

It is also applied to diverse inferior officers, among us called *graves*, *garçons*. Thus all the servants in the French king's chambers, wardrobe, &c. who do the lesser offices thereof under the proper officers, are called *garçons de la chambre*, or *de la garde-robe*, &c.

GARD. See **GUARD**.

GARD, restaurant de. See **RAVIVEMENT**.

GARD, Corps de. See **CORPS**.

GARDANT, in Heraldry. See **GUARDANT**.

GARBECAUT, or **GARBED COED**, is a watch, that which stops the sales, when wound up, and for that end is driven up by the firing. Some call it *guardant*; others, *guard du jour*.

GARDEN, an inclosure or plot of ground, curiously cultivated, and furnished with variety of plants, flowers, fruits, &c.

Gardens are distinguished into *flower-gardens*, *fruit-gardens*, and *litten-powens*; the first are for pleasure, and ornament, and therefore, are placed in the most conspicuous parts; the two latter are for service, and therefore, made in more obscure and retired places. These were formerly distinct, but they are now generally united, because they both require a good soil and exposure, and are equally placed out of the view of the House. The principal things to be considered with respect to a *pleasure garden*, are the situation and exposure, the soil, water, prospect, and the method of designing or laying it out.

As to situation, it should be neither too high, nor too low; for the winds in one of these extremes, and the damps and vermin in the other, are equally to be avoided. The sides of a hill are always the most eligible; and if the declivity be easy, and there are springs of water for supplying fountains, canals, and cascades, and for fertilizing the adjacent valleys, the situation is peculiarly excellent. *Gardens* on level ground have their advantages, and are less expensive; but they want prospect, and several other agreeable circumstances that attend those on the sides of hills, not too steep. See **EXPOSURE**.

The second article, or the soil, is greatly to be regarded, as it is not possible to make a good *garden* when this is bad. Great expences may be incurred in meliorating the ground; and when that is done, the advantages of it will be lost in a little time; nay, where three feet of good earth have been laid on the surface of a whole *garden*, when the trees have been rooted enough to strike into the natural bottom, the whole plantation has been known to dwindle away. Places naturally producing health and shelter are to be rejected; and where the trees are seen

to be stubbed, and fluted, it is an ill omen. When the grass grows well, and there is not less than three feet earth, *gardens* are sure to succeed. The ground must not be too thin, nor of all things a hard thin clay, which is most to be avoided of all soils for gardening. A deep, rich, black mould, is best for plants; sandy land is warm and forward, and good for flowers; a stony land is cold and backward; but both may be corrected and improved by composts of different kinds, suited to their respective qualities. A third requisite is water, without which a *garden* must suffer extremely in drought; besides the usefulness of it in forming ornamental canals, cascades, &c. To this may be added a very advantageous and pleasing, though not absolutely necessary thing, the prospect of a pleasant country. A *garden* planted in a low place, without any kind of prospect, will not only be disagreeable, but unwholesome. With regard to the method of designing and laying out a pleasure *garden*, it may be observed, that the area of a handsome *garden* may take up thirty or forty acres, not more, and the following rules should be observed in the disposition of it. There should always be a descent from the house to the *garden* of not fewer than three steps; this will render the house more dry and wholesome, and the prospect on entering the *garden* more extensive.

The first thing presenting itself to view in a pleasure *garden* should be, an open lawn of grass, whose extent should be proportioned to that of the *garden*; in a large *garden* it should not be less than six or eight acres; but in smaller *gardens* the width of it should be considerably more than the front of the house, and its depth about one half more than the width. The figure of this lawn need not be regular; and if on the face there are trees planted irregularly by way of open grove, some of which may be planted furthest upon the lawn than others, whereby the regularity of the lawn will be broken, the *garden* will more resemble nature; for it should be always considered, that a *garden* is only a natural spot of ground destined and ornamented.

The great art in laying out *gardens* is to adapt the several parts to the natural position of the ground, so as to have as little earth to remove as possible. Instead of levelling hills in order to form large terraces, stiff slopes and green parterres, or sinking of hollows, and raising of hills, it is much better only to smooth and well turf the surface of the ground, which would have a more pleasing effect, and be attended with a less expense of time and money. The *gardens* should be encompassed with a dry gravel walk, for the convenience of walking in damp weather. This walk may lead through the different plantations, winding about gently in an easy natural way, which is much preferable to long straight walks. However, the turns should be few and concealed, and so contrived as to lead into shade as soon as possible, and into some plantations of shrubs for shelter; for without shade and shelter no *garden* can be pleasing. When the boundaries of the *gardens* are fenced with walls or pales, they should be hid by plantations of flowering shrubs, intermixed with laurels, and other evergreens. In situations where there is a good supply of water, it may be conducted through the *garden* in streams or rivulets, and these, if they are formed with judgment, will have a better effect, and be much more salutary and refreshing than large ponds or canals of stagnant water, which render the air damp and unhealthy. If wildernesses are designed, they should not be cut into bars, and other ridiculous figures, nor formed into mazes or labyrinths, but the walks should be noble and shaded by tall trees; and the spaces of the quarters planted with flowering shrubs and evergreens; and on the sides of the walks may be scattered hardy sorts of flowers, which will thrive with little care. These wildernesses should not be situated too near the house; but a communication and undershade may be made between them and the house by open groves. Buildings properly and tastefully introduced, statues and cascades, &c. where a constant supply of water can be obtained, will greatly contribute to the ornament of a pleasure *garden*. When the ground is naturally uneven, with gentle ascents and declivities, there may be so managed as to be rendered great beauties; for this purpose the inequalities of the ground should not be cut into regular stiff slopes and amphitheatres, but be properly planted with clumps of trees or shrubs, and the sloping sides smoothed and left in their natural position. In forming a new *garden*, or altering the disposition of an old one, great care should be taken to preserve all the good trees, wherever they can be rendered either useful or ornamental; the trees and shrubs that are introduced should also be adapted to the situation and soil of the *garden*, and be allowed sufficient room. Before a *garden* is planned out, it should be considered what it will be in

twenty or thirty years time, when the trees and shrubs are grown up and spread; and the general distribution of the parts of a *garden* should be regulated by this prospect, as well as by the situation of the ground. The great art of designing is to adapt the plan to the situation, to make the most of the inequalities of the ground, to proportion the number and sorts of trees and shrubs to each part of the *garden*, and to flout out, from the view of it, no objects that either are or may be made ornamental. Miller.

The chief furniture of pleasure *gardens*, *see*, parterres, vases, glades, groves, compartments, quincunxes, verdant hills, arbours, walks, mazes, labyrinth, fountains, cabinets, cascades, canals, terraces, &c. See each under its proper article.

GARDEN, LAYING. There are certain general rules always to be observed in making a *garden*, which will render it much cheaper and more convenient than it otherwise is, as a venture, without the consideration of them. It should always be placed behind a house, that it may be both sheltered and kept out of sight, and always should be as near as may be to the house, that the things may be ready, and cost no great labour nor expense in carrying. A square or oblong is the best figure for the *garden*, but this is not necessary, since all irregularities may be hid by the quarters. The soil must neither be very wet, nor very dry, nor too stiff; and if there are any rising, in any part of the ground, they are by no means to be levelled, as they will be of great use for different crops of several kinds. This *garden* must be fully exposed to the sun, and by no means overlaid by trees. See EXPOSITION. The quantity of ground is to be proportioned to the size of the family which it is to supply; for a small one, an acre of ground will be enough, and three seldom requires more than three or four acres. It should be walled all round with walls twelve feet high for the reception of fruit-trees, and the ground, when the soil is strong and stiff, should be ploughed or dug up three or four times before any thing is planted in it, and if it be thrown up in ridges to receive the frost in winter, this will be of great service to ripen and loosen its roots.

In this case it should be manured with sea-coal ashes, the cleanings of the streets of large towns, or sea sand, as also with rotten wood, and decayed and purified vegetables. On the contrary, if it be light and warm, it must be manured with rotten horse dung; and if horse-dung be used, it must be always very well rotted first. The soil must be at least two feet deep, and there must be a supply of water, which, if it can be contained in basins, or reservoirs, will be very convenient and advantageous.

In the planting a fruit or kitchen *garden*, if the soil be a hungry gravel, or sand, Mr. Switzer directs the holes where the trees are to be planted, to be dug two feet deep, and three or four wide, and filled with rotten horse or cow dung, mixed with rich mould. As soon as the walls are built, the first thing to be done is the laying out of the borders under them, which should be at least eight or ten feet broad; and in those which are exposed to the south, the early crops are to be planted, and the latter on those to the north.

The trees being taken out of the nursery, the biggest roots are to be shortened to about six inches; all the small fibres to be taken off, and the head to be pruned, so as not to leave above two branches; and those not above six inches long.

The wall trees are to be placed as far from the wall as may be, that there may be the more room for the roots to spread; then, filling up the whole with mould, there remains nothing but to secure the roots from the winter's frost, by covering the spot with straw, fern, dung, &c. and in summer from the sun by sand and pebble stones.

For trees planted in borders the common practice is to make a trench by the wall-side, two feet broad, and as many deep; this trench they fill with old dung, mixed with earth, lightly laid, near as high as the borders are intended to be, and then trodden down to half the height. In the places where the trees are intended to be, it is prudent to plant the trees shallow, and to raise the earth about them; especially in a wet, clayey soil. See PLANTING AND PRUNING.

It is an observation of some importance, that wall trees and fruit thrive best when the walls that run parallel to them are gravel covered at the top, of the top being thereby rendered in them, than if they were grass. And that no sort of tall trees are to be suffered to grow in any of the opposite borders, or intermediate spaces, so that their shade might reach to the south-east, or south-west walls. The places near the walls are most advantageously filled with dwarf trees.

No large or deep-rooting plants should ever be set near the

the roots of the wall-fruit trees, but the beans and peas, required to be early, should be planted in the other parts of the garden, and sheltered by moveable reed hedges, which will screen and forward them as well as the walls. The next thing to be done, is the laying out the ground into quarters. These should never be too small, but in a little garden, it is better to have only a few of them. They must be surrounded with espaliers of fruit-trees, and have walks suited between them, which, in a small garden, ought to be six feet wide; in a large one, ten; and on each side the walk, there should be allowed a border of three or four feet broad, between its edge and the espaliers. On these borders, small fallowing, or any thing that does not remain long, nor root deep, is proper to be sown. If the walks are covered with lime-rubbish or sand, instead of being turfed, it will be an advantage to the fruit in the espaliers, though it takes off from the beauty of the garden. The best figure for the quarters is either a square, or an oblong; but when the nature of the ground does not admit this, they may be triangular, or of any other form. The ground in these quarters should never be tawn, or occupied by the same crop, for two years together; and when any part of the ground is not used, it should be trenched up in ridges, to receive the better the benefit of the dews and froit.

In one of the quarters, which is nearest the stables, and is most defended from bad weather, should be the beds for cucumbers, melons, and other productions of the hot-bed; and it is a very good method to surround that part with a reed hedge, which both shelters and hides the beds from sight. The square should always be large enough for the beds of two years.

The most important points of culture and management are the well digging and manuring the soil, and the giving a proper distance to each plant. The quarters and dunghills are both also to be kept clear of weeds; for if they are suffered to scatter their seeds on the dunghills, it is vain to root them out of the garden, as they will be continually renewed from thence. Miller's *Gardener's Dict.*

Robbing gardens and orchards of fruit growing in them, stealing underwoods and hedges, and stealing or destroying any turneps, or the roots of madder, when growing, are punishable criminally, by whipping, small fines, imprisonment, and satisfaction to the party wronged, according to the nature of the offence, by the statutes 43 Eliz. cap. 7. 15 Car. II. cap. 2. 21 Geo. II. cap. 26. and 31 Geo. II. cap. 35. And by stat. 6 Geo. III. cap. 36. and cap. 48. the stealing by night of any trees, or of any roots, shrubs, or plants to the value of 5s. is made felony in the principal aiders and abettors, and in the purchasers, knowing the same to be stolen; and the stealing of any timber trees, as oak, beech, chestnut, walnut, ash, elm, cedar, fir, spruce, lime, sycamore, and birch, and of any root, shrub, or plant, by day or night, is liable to pecuniary penalties for the two first offences, and for the third is a felony, liable to transportation for seven years.

GARDENS, *pendant, or hanging.* See *PENSILES horti.*

GARDENIA, *Cape jasminum*, in Botany, a genus of the *pentandria monogyna* class: the style is elevated, and composed of two lobes; the calyx is divided into vertical segments, and the fruit is a polyspermous berry. There is only one species.

GARDENING, *Horticulture*, the art of cultivating a garden.

Gardening has, in all ages, been esteemed an employment worthy the greatest heroes and philosophers: the emperor Dioclesian, at Solons; and Epicurus and Metrodorus, at Athens, have ennobled the art beyond all encomium.

Goetzius, superintendent of Lubek, printed a dissertation in 1756, intitled *Kunst des Gärtners*, &c. de Erasmi Hortorum cultibus, of the learned men who have loved and cultivated gardens: among which number he ranks Adam Gregory, Nazzareno, St. Augustine, Pliny, and Cicero; nor should he have forgot the elder Cato, Democritus, Plato, and his academy.

The fleur le Notre first carried gardening to any thing of perfection; M. la Quintinie has gone yet farther; nor have our own countrymen been wanting to its improvement; as London, Wise, Bradley, Laurence, Fairchild, Miller, Brown, &c.

M. Fatio has lately applied mathematical reasoning to gardening, and shewn how to make the best use of the sun's rays in gardens.

The principal operations in gardening are planting, transplanting, engraving, inoculating, pruning, lopping, &c. all which see under their proper articles.

Other particulars relating to the art of gardening, see under *PINCHING, VARIATION, NURSERY, SEED, GREEN-HOUSE, HOT-BED, FRUIT-TREE, DWARF, SALLEY, &c.*

VOL. II. N° 147.

GARDENING, in *Faltery*. To garden a hawk, is to put her on a turf of grass, to cheat her.

Some also use the same phrase for the giving her an airing, or letting her fly at large.

GARDROBE. See *WARD-ROBE.*

GARDEYN. See *GUARDIAN.*

GARDIAN. See *GUARDIAN.*

GARDON, in *Ichthyology*, the name of a fish of the roach kind, supposed by many not to differ in any thing essential from the common roach of the English rivers; some authors call it the *gardon saxosus*, and cephalus; others *leuciscus*.

GARDUS, in *Ichthyology*, a name given by some writers on fishes to that kind of cyprinus, called by Gelfner and others the fargus. See *GARDON* and *CEPHALUS*.

GARE, in our *Old Writers*, a coarse wool, full of stirring hairs, such as grow about the flanks of sheep. 31 Edw. III. cap. 8.

GAR-FISH. See *ESOX* and *ACUS*.

GARGANEY, in *Ornithology*, *anas garganula* of Linnaeus, the name of a fresh-water fowl of the duck kind; it is somewhat larger than the teal, but very like it in shape. Its beak, legs, and feet, are of a deep lead colour; the upper part of the head is dusky, but it has on each side a white streak drawn from the eyes to the back part of the head; the throat and lower part of the neck are variegated with a white and reddish brown; just under the beak it has a black spot; the breast is beautifully variegated with transverse undulated lines of black, and a dusky brown; the belly is white or yellowish. The female is smaller than the male, and has not the bright colours about the head, which are so beautiful in that. It has an obscure white mark over the eye, and the rest of the plumage is of a brownish ash colour. These birds are in many places called the *famine teal*.

GARGARISM, GARGLE, in *Medicine*, a liquid form of remedy, for disorders in the mouth, gums, throat, &c.

The word is Greek, γαργαρίσμις, formed of γαργαρίζω, *salutem*, to wash, or the Hebrew *gargara*, the throat. *Gargarismi* are composed of honey, salt, syrup, spirits, vinegar, waters, and decoctions; and produce their effects, by cleansing, lubricating, &c. the parts.

Gargles are peculiarly useful in fevers and sore throats; and they have this advantage above many other medicines, that they are easily procured and prepared: an useful *gargle* for softening and cleaning the mouth may be made with a little barley water and honey, acidulated with vinegar. *Gargles* bear different applications according to the uses to which they are applied. An *anesthetizing gargle*, made by mixing six ounces of water, with one ounce of honey and a dram and a half of nitre, or by adding an ounce of honey and half an ounce of spirit of sal ammoniac to the emollient *gargle*, may be used in the inflammatory quinsy or in fever, for cleaning the tongue and fauces. A good *gargle* for this purpose may be made with strong fage tea, sweetened with honey and steepened with vinegar. The *emollient gargle*, made by mixing six ounces of rose-water with half an ounce of syrup of clove July-flowers acidulated with spirit of vitriol, cleanses the tongue and fauces, and serves also for a gentle repellent.

The *divergent gargle*, prepared by mixing a pint of the emollient *gargle* with an ounce of tincture of myrrh and two ounces of honey, serves to cleanse excretions and to promote the excretion of tough viscid saliva.

The *emollient gargle*, made by boiling an ounce of marsh-mallows roots, and two or three figs in a quart of water till near one half of it be consumed, and straining out the liquor, is beneficial in fevers, when the tongue and fauces are rough and parched, to soften these parts and promote the discharge of the saliva. Sir John Pringle recommends a decoction of figs in milk and water, with the addition of sal ammoniac, as an useful *gargle* in the inflammatory quinsy, or inflammation of the fauces.

GARGET, a disease of cattle, consisting in a swelling of the throat, and the neighbouring parts, to prevent which, bleeding in the spring is recommended.

GARGIL, a distemper in geese, which by stopping the head frequently proves mortal. Three or four cloves of garlic, beaten in a mortar, with sweet butter, and made into little balls, and given the creature fasting, are the ordinary cure.

GARHANA, in *Ichthyology*, a name by which some have called a large Brazilian fish, of the shape of our carp, more usually known among authors, by its Brazilian name *ACARAAYA*.

GARICON, in the *Materia Medica*, a name given by the Arabian writers to the drug called *agaric* by the ancients.

The Arabians have said nothing of this drug, but what they have transcribed from the Greek of Dioscorides and others; it is certain, however, from the concurrent testi-

mony of all the ancients, as to the form, nature, and virtues of AGARIC, that there was not the same substance which we call by this name.

The ancients knew two kinds of what they called agaric; they distinguished these by the common terms of male and female; the male was a root resembling the filipium of a cubit long, and of an inch or two in diameter; the female was the corrupted wood of certain trees, particularly of the cedar, and other odoriferous woods.

Pliny makes it indeed the decayed wood of the oak, which shines like fire in the dark, and calls it the fungus, but this was not the agaric of the Greeks.

The female agaric, or the decayed wood of the cedar, was what they gave as an antidote and cordial; the male, or as others called it, the black agaric, was poisonous. Dioscorides places it among the poisonous roots, and Aretæus condemns it, as hard and unfit for internal use; the other, or female agaric, being soft, friable, and tender. When it was thus in a great degree, however, it was condemned by the more accurate writers; and Dioscorides, in particular, condemns the agaric of Cilicia and Galatia as too friable, and of no value: so that they seemed to fix upon a proper stage in the decay, as the necessary qualification of good agaric.

GARIDELLA, is named by Tournefort in honour of Dr. Garidel, professor of physic at Aix in Provence, in *Batany*, a genus of the *Scandria trigyna* class. Its characters are these: the flower hath no petals, but five oblong equal nectaries occupy their place, which are bilabiate. It hath eight or ten awl-shaped stamens, which are shorter than the empanment. In the centre are situated three compressed perianths, which become three oblong compressed capsules with two valves inclosing several small seeds. We know but one species of this genus.

GARLAND, an ornament for the head, made in manner of a crown or diadem.

The word is formed of the French *guirlande*, and that of the barbarous Latin *garlanda*, or Italian *garlanda*. Menage traces its origin from *grati*, through *gyralis*, to *gyralis*, *gyralis*, *gladialis*, and at length *garlanda*, and *guirlanda*; so that *guirlanda*, and *garland*, are descended, in the sixth or seventh degree, from *grati*. Hicks rejects this derivation, and brings the word from *garid banda*; which, in the northern languages, signify, a *reign* or *artfully wrought with the hand*.

Garlands are a sort of chaplets, made of flowers, feathers, or even of precious stones, but especially of flowers; to which the word, in our language, is more immediately appropriated. Janus places in antiquity for the inventor of *garlands*. Athen. Dign. lib. xv.

Garlands also denote ornaments of flowers, fruits and leaves intermixed; anciently much used at the gates of temples, where feasts, or solemn rejoicings, were held; or at any other places where marks of public joy and gaily were desired; as at triumphal arches, tournaments, &c. *Garlands*, or trifles, were also put on the heads of victims, in the ancient heathen sacrifices. St. Paulinus, in his poem on St. Felix, does not forget the *garlands*, and crowns of flowers placed at the door of the church, and on the tomb of that saint.

The Italians have a sort of artifice called *festarello*, whose office is, to make *garlands*, or tellows, and other decorations for feasts.

GARLAND, in a *Ship*, denotes a collar of ropes, wound about the head of the main-mast, to keep the shrouds from gallies.

GARLAND is also a sort of net, whose opening is extended by a wooden hoop of sufficient size to admit a bowl or platter within it. It is used by the sailors as a locker or cupboard to contain their provisions, being hung up to the deck, within the binnacle, where they commonly mess between decks.

GARLAND, *Shot*, is a piece of timber nailed horizontally along the ship's side from one gun-port to another, and used to contain the round shot ready for charging the great guns in battle. For this purpose it is furnished with several semi-globular cavities, corresponding to the size of the cannon balls contained in it.

GARLICK, *Allium*, in *Batany*, a genus of the *hexandria monogyna* class. Its characters are these: the flowers are included in one common spathe, and are composed of six oblong erect petals, and six awl-shaped stamens, the length of the petals, and crowded with oblong samaras; the germens, which supports a single style, crowned by an acute stigma, becomes a three-cornered capsule, opening into three parts, having three cells, filled with roundish seeds. Miller enumerates nineteen and Linnaeus thirty-eight species.

The common *garlick* and romaine are easily propagated by planting the clove, or small bulbs, in the spring, in beds, about four or five inches distant from each other, keeping them clear from weeds. About the beginning

of June, the leaves of the first root should be tied in knots to prevent their spinning, or running to seed which will greatly enlarge the bulb. In the middle of July, the leaves will begin to wither and decay, at which time they should be taken out of the ground, and hung up in a dry room, to prevent their rotting, and may be thus preserved for winter use. The roots of the second sort may be left in the ground till the leaves are decayed, and their bulbs may then be taken up and dried.

Garlick is an extremely active and penetrating medicine. It is of the number of those roots which ought always to be used fresh and full of juice, not dried; some esteem it the greatest of all alexipharmics. To warm and stimulate the solids, attenuate thick humours, and resist putrefaction are its primary virtues: on this account it is improper in hot bilious constitutions; but in cold, sluggish, phlegmatic habits, it proves a salutary and powerful corroborant, expectorant, diuretic, and sudorific. The German physicians frequently carry a clove of *garlick* in their mouths, when they visit patients in malignant fevers: with us it is more in use among country people, than in the shops. They give a decoction of *garlick* in milk, as a remedy for worms, and also in the colic, and in suppressions of urine. Its most constant use, however, is in asthma, and catarrhus of the breast, in which it promotes expectoration. It has likewise been found serviceable, in the beginning of dropsies, and for preventing a new accumulation of water, after evacuation. Sydenham relates, that he has known the dropsy cured by the use of *garlick* alone.

Whatever may be the virtues of *garlick* it ought to be used in small doses, and that not too frequently, because, if long continued, it is apt to heat and inflame the viscera.

Garlick is sometimes employed externally, in unguents and lotions, as an antiseptic and discutient; and is frequently an ingredient in the stimulating epithems, applied to the soles of the feet, in the low stage of acute dysentery, for raising the pulse, and relieving the head; and it is much commended by Sydenham for this purpose. The roots lose considerably of their weight by drying; so that six grains dry may be looked upon as equivalent to fifteen grains of the fresh root. The fresh root yields, on expression, about a fourth of its quantity of a very viscid glutinous juice; and both the fresh and dry root communicate their virtue to water by warm infusion. A quart of water poured boiling hot on a pound of the fresh root sliced, with a proper quantity of sugar, makes the syrup of *garlick* of the shops. The oxymel of *garlick* is prepared by infusing an ounce and a half of the fresh root in half a pint of vinegar, and dissolving in the strained liquor, by the heat of a water-bath, ten ounces of clarified honey. The ill smell of the *garlick* may be in some degree prevented by boiling two drams of cartilage, and the same quantity of sweet fennel seeds bruised in the vinegar, before the *garlick* is put in. The *garlick* should never be boiled, either with vinegar or watery liquors, because the virtues of this root, residing in an essential oil, are exhaled with the steam. Rectified spirit of wine, digested on dry *garlick* roots, extracts its virtues more readily and perfectly than either water or vinegar. Lewis's Mat. Med.

GARLIC, wild, a name given to a species of *ONION*.

GARLICK, *pear*. See *CRATEVA*.

GARNET, in *Natural History*. See *GRANATE*.

GARNET, in a *Ship*, is a tackle having a pendant coming from the head of the main-mast, with a block loosely seized to the main-stay, just over the hatch-way; in which block is received the runner, which hath a hook at one end, in which are hitched the flings; and at the other end is a double block, in which the fall of the runner is reeved; so that by its means any goods, or casks, that are not over heavy, may be hoisted and hoisted into, or out of the ship: when this *garnet* is not used, it is fastened along by the flay at the bottom of it.

GARNET, *claw*. See *CLEW-garnet*.

GARNISH, in some ancient writings and statutes. To garnish the heir, signifies to warn the heir. 27 Eliz. cap. 2.

GARNISHING, in *Law*, the party in whose hands money is attached within the liberties of the cities of London; so called in the Statute book, because he has had *garnishment*, or warning, not to pay the money, but to appear and answer to the plaintiff-creditor's suit.

GARNISHING is popularly used for the furniture, apparel, or fortment, necessary for the using or adorning any thing.

The word is French, formed of the verb *garnir*, to furnish, or fit out.

The *garnishing* of a dish consists of certain things which accompany it, either as a part and ingredient thereof; in which sense pickles, mushrooms, oysters, &c. are *gar-*

garish.

garnishing: or as a circumstance, or ornament; as when leaves, flowers, roots, &c. are laid about a service to amuse the eye.

The same word is used for the finer herbs, fruits, &c. laid about a fallot: *garnishings* are of lemon, pistachos, pomegranate, yolks of hard eggs, artichoke-bottoms, capers, truffles, sweetbread, &c.

GARNISHMENT, in *Law*, denotes a warning given any one to appear, for the better furnishing of the cause, and court. Thus, if one be sued for the detinue of certain charters, and says, they were delivered to him, not only by the plaintiff, but by J. S. also; and therefore prays, that J. S. may be warned to plead with the plaintiff, whether the conditions are performed, or no. In this petition he is said to pray *garnishment*; which may be interpreted, a warning to J. S. to provide himself for a defence, or else a furnishing the court with all parties to the action, whereby it may thoroughly determine the cause.

GAROSMUS, in *Botany*, a name used by some authors for the *arripex olida*, or *flinking orchid*, a very stinking low plant common on dunghills.

GARRISON, in the *Art of War*, a body of forces disposed in a fortress, to defend it against the enemy, or to keep the inhabitants in subjection, or even to be subsisted during the winter season.

Du-Cange derives the word from the corrupt Latin *garnis*: which the latter writers used to signify all manner of munition, arms, victuals, &c. necessary for the defence of a place, and the sustaining of a siege.

Garrison, and *winter quarters*, are sometimes used indifferently for the same thing; and sometimes they denote different things.

In the latter case, a *garrison* is a place wherein forces are maintained to secure it, and where they keep regular guards; as, a frontier town, a citadel, castle, tower, &c. The *garrison* should always be stronger than the townsmen.

Winter quarters signify a place where a number of forces are laid up in the winter season, without keeping the regular guard. The soldiers, therefore, like better to be in winter quarters than in *garrison*.

GARRISON carriages are those on which all sorts of *garrison* pieces are mounted. See **CARRIAGE**.

GARRISON gun consist of 42, 36, 24, 18, 12, 9, and 6 pounders; and they are made either of brass or iron. The following table exhibits their dimensions.

Brass Garrison Pieces.					Iron Garrison Pieces.				
Calibres	Length	Weight			Calibres	Length	Weight		
	f. l.	q.	qr.	lb.		f. l.	c.	qr.	lb.

6	5	3	9	1	4	5	4	8	0

See **GUN**.

GARRULUS *Bohemius*, the *Bohemian magpie*, a name given by some to the bird more usually called *AMPELLUS*, from its love of grapes.

GARRULUS *Arvensis*, in *Ornithology*, the name given by authors to the species of magpie commonly called the *ROLLER*, a very beautiful variegated bird, brought to market in Italy, and some other places.

GARTER, *versipede*, a figure to keep up the stockings: it is also particularly used for the badge or cognizance of a noble order of knights, hence denominated the

Order of the GARTER, a military order, next in dignity after the nobility, instituted by king Edward III. in 1344 under the title of the *sovereign and knights-companions of the most noble order of the Garter*.

This order consists of twenty-five knights, or companions, generally peers or princes; whereof the king of England is the sovereign, or chief.

They wear a *garter*, set with pearls and precious stones on the left leg, between the knee and calf, with this motto: *honi soit qui mal y pense*, q. d. *flume to him that thinks evil thereof*: and they bear this motto surrounding their arms. The meaning of which motto is said to be, that king Edward having laid claim to the kingdom of France, retorted shame and defiance upon him that should dare to think amiss of the just enterprise he had undertaken for recovering his lawful right to that crown; and that the bravery of those knights whom he had elected into this order was such: would enable him to maintain the quarrel against those who thought ill of it.

They are a college or corporation, having a great and

little seal; their officers are a prelate, chancellor, register, king at arms, and usher.

Besides which, they have a dean and twelve canons, with petty canons, vergers, and twenty-six pensioners, or poor knights.

The prelate is the head; and the office is vested in the bishop of Winchester: next to him is the chancellor, which office is vested in the bishop of Salisbury, who keeps the seals. All these officers, except the prelate, have fees and pensions.

The order is under the patronage and protection of St. George of Cappadocia, the tutelar St. of this kingdom. Their college is held at the castle of Windsor, within the chapel of St. George, and the chapter-house, erected by the founder for that purpose. Their robes, &c. are the *garter*, decked with gold and gems, and a buckle of gold, to be worn daily; and at feasts and solemnities, a fur-coat, mantle, high velvet cap, collar of SS's, composed of robes enamelled, &c.

The mantle is the chief of these vestments made use of on solemn occasions. Its colour is by the statutes appointed to be blue. The length of the train of the mantle only distinguishes the sovereign from the knights-companions; to the collar of the mantle is fixed a pair of long strings, anciently wove with blue silk only, but now twisted round, and made of Venice gold and silk, of the colour of the robe, with knobs or buttons, and tassels at the end. The left shoulder of the mantle has from the institution been adorned with a large *garis*, with the device 11081 3017, &c. within this is the cross of the order, which was ordained to be worn at all times by king Charles I. At length the star was introduced, which is a sort of cross, irradiated with beams of silver. The collar is appointed to be composed of pieces of gold in fashion of *garters*, with the ground enamelled blue, and the motto gold.

When they wear not their robes, they are to have a silver star on the left side; and they commonly bear the picture of St. George, enamelled on gold, and beset with diamonds at the end of a blue ribbon, crossing the body from the left shoulder. They are not to appear abroad without the *garis*, on penalty of 6s. 8d. paid to the register.

The manner of electing a knight-companion into this most noble order, and the ceremonies of investiture, are as follow. When the sovereign designs to elect a companion of the *garter*, the chancellor of the order draws up the letters, which, passing both under the sovereign's sign manual, and figure of the order, are sent to the person by *Garter* principal king at arms, and are to this effect:

"We, with the companions of our most noble order of the *garter*, assembled in chapter, holden this present day at our castle at Windsor, considering the virtuous fidelity you have shewn, and the honourable exploits you have done in our service, by vindicating and maintaining our rights, &c. have elected and chosen you one of the companions of our order. Therefore, we require you to make your speedy repair unto us, to receive the enigma thereof, and be ready for your installation upon the day of this present month." &c. The *garter*, which is of blue velvet, bordered with fine gold wire, having commonly the letters of the motto of the same, is, at the time of election, buckled on the left leg by two of the senior companions, who receive it from the sovereign, to whom it was presented on a velvet cushion by *Garter* king at arms, with the usual reverence, whilst the chancellor reads the following admonition enjoined by the statutes: "To the honour of God omnipotent, and in memorial of the blessed martyr St. George, tie about thy leg, for thy renown, this noble *garter*; wear it as the symbol of the most illustrious order, never to be forgotten or laid aside; that thereby thou mayest be admonished to be courageous, and having undertaken a just war in which thou shalt be engaged, thou mayest stand firm, valiantly fight, and successfully conquer." The princely *garter* being thus buckled on, and the words of its signification pronounced, the knight elect is brought before the sovereign, who puts about his neck, kneeling, a sky-coloured ribbon, to which is appendant, wrought in gold within the *garter*, the image of St. George on horseback, with his sword drawn, encountering with the dragon. In the mean time the chancellor reads the following admonition: "Wear this ribbon about thy neck, adorned with the image of the blessed martyr and soldier of Christ St. George, by whose intercession provoked, thou mayest so overpass both prosperous and adverse adventures, that having stoutly vanquished thine enemies both of body and soul, thou mayest not only receive the praise of this transient combat, but be crowned with the palm of eternal glory." Then the knight elect kisses his sovereign's hand, thanks his majesty for the

great

great honour done him, rises up and salutes all the companions severally, who return their congratulations.

The order of the *Garter* appears the most ancient and noble lay-order in the world. It is prior to the French order of St. Michael, by 50 years; to that of the golden Fleece, by 80 years; to that of St. Andrew, by 190 years; and to that of the Elephant, by 209 years.

Since its institution, there have been eight emperors and twenty-seven or twenty-eight foreign kings, beside numerous foreign princes, enrolled as companions thereof.

Its origin is somewhat differently related: the common account is, that it was erected in honour of a *garter* of the countess of Salisbury, which she dropped in dancing and which King Edward picked up; but our best antiquaries for this abide as fabulous.

Camden, Fern, &c. take it to have been instituted on occasion of the victory obtained over the French at the battle of Cressy; that prince, say some historians, ordered his *garter* to be displayed, as a signal of battle; in commemoration whereof, he made a *garter* the principal ornament of the order erected in memory of this signal victory, and a symbol of the indissoluble union of the knights.

Fa. Papbroche, in his *annals* on St. George, in the third tome of the *Acta Sanctorum*, published by the Hollanders, has a dissertation on the *Order of the Garter*. This order, he observes, is so less known under the name of St. George than under that of *garter*, and that, tho' it was only instituted by King Edward III. yet it had been projected before him by King Richard I. in his expedition to the Holy Land, if we may credit an author who wrote under Henry VIII. Papbroche adds, however, that he does not see what that author grounds his opinion on; and that, though the generality of writers fix the epocha of this institution to the year 1350, he rather chafes, with Froissart, to refer it to the year 1344, which agrees better with the history of that prince, where we read, that he called an extraordinary assembly of knights that year.

It appears from Balle's Chronicle, lib. vi. quoted by Granger in the Supplement to his Biographical History, that this order was devised by Richard I. at the siege of the city of Acre, when he caused twenty-six knights, who firmly stood by him, to wear thongs of blue leather about their legs, and that it was perfected in the nineteenth year of Edward III.

In 1551, Edward VI. made some alterations in the ritual of this order: that prince composed it in Latin, the original whereof is still extant in his own hand-writing. He there ordained, that the order should no longer be called the order of St. George, but that of the *Garter*; and, instead of the George, hung at the collar, he substituted a cavalier, bearing a book on the point of his sword, with the word *pretulsi* graven on the sword, and *verbum Dei* on the book; with a buckle in the left-hand and the word *fili* thereon. Lurey.

For a farther account of the order of the *Garter*, see Camden, Atholme, Dawson, Leland, Polydore Virgil, Heylin, Logan, Glover, and Evelyn.

Erhard, Cellius, and the prince of Orange, add Papbroche, have given descriptions of the ceremonies used at the institution of knights. A Cistercian monk, named Mendocius Belvaetus, has a treatise, intitled *La Garretiere*, or *Speculum Anglicanum*, since printed under the title of the *Catechism of the Order of the Garter*; wherein he explains all the allegories, real or pretended, of those ceremonies, with the moral significations thereof.

GARTER principal king at arms. This office was instituted by Henry V.

Garter, and *principal king at arms*, are two distinct offices united in one person: *Garter's* employment is to attend the service of the order of the *garter*; for which he is allowed a mantle and badge, a house in Windsor-castle, and pensions both from the sovereign and knights, 25*l.* lastly, fees. He also carries the rod and sceptre at every feast of St. George, when the sovereign is present, and notifies the election of such as are new chosen; attends the solemnity of their installations, and takes care of placing their arms over their seats; and carries the *garter* to foreign kings and princes, for which service it has been usual to join him in commission with some peer, or other person of distinction.

Garter's oath relates only to services being performed within the order, and is taken in chapter before the sovereign and knights. His oath, as king at arms, is taken before the court martial.

GARTER is also a term in heraldry, signifying the moiety, or half of a bend.

GARTH. See FISHGARTH.

GARTH is used in some parts of England for a little back-side or clove. It is an ancient British word. *Gwath*, in

that language, signifies *garden*, and is pronounced and written *garth*.

The word is also used for a dam or wear, &c.

GARTH-men is used in our statutes for those who catch fish by means of fish-garths or weirs.

By statute it is ordained, that no fisher, nor *garth-men*, shall use any nets or engines to destroy the fry of fish, &c. 17 Ric. II. cap. 9. The word is supposed by some to be derived from the Scotch word *gar*, which signifies *forced*, or *impelled*; because fish are forced by the wear to pass in a loop, where they are taken.

GARUM, a word in very common use among the old writers on medicine, who expressed by it a pickle, in which fish had been preferred. The principal kind of fish they preferred in this manner was the mackerel.

The *garum* principally consisted of the juices of the fish and salt; but we find the old writers speaking of several kinds of it: one they called *Spanish garum*, from the place whence they had it; another kind from its colour was termed the black *garum*: this last kind seems to have been that called *sagnum* by the Latin poets, as if the faces and remains of the fish were left among it, and by others *garum sanguinum*, from its being sometimes tinged with their blood to a reddish colour. The Romans sometimes called the *Spanish* kind, which was esteemed the best, *garum sagnum*; and Galen says, that the black *garum* was called *asporum*, but he only means by this, that it was used in the preparations called *aspora*. It served to dilute them, and thence took the name of them to itself, by way of distinction from the *Spanish*, and other kinds, not used to this purpose. Pliny tells us, that *garum* was composed of all the offals of fish, of every kind; macerated in salt; it had its name, he says, from its being originally made of a fish, called by the Greeks *garos*, but in his time the best seems to have been made with the mackerel; but that there were several other kinds used both in food and medicine, some of which must have been made from scarce fish, for they were of great price. They were used in glysters, and externally applied in several kinds of cutaneous eruptions: the ancients had a great opinion of them in glysters, for removing the pain in the fistula, and other like cases; and the coarser sorts were their common medicine for curing cattle of the scab, by making incisions in the skin, and laying over the raw cuts wetted with it. See Strabo, lib. iii. 109. Plin. lib. xxi. cap. 8.

The true way in which the ancients prepared their *garum*, which they so much valued as a delicacy at their tables, is unknown to us; but it appears that some kinds of *garum* had no fishy matter in them, from Aetius, who gives the following prescription of a liquor, which he calls by this name: take of common water thirty-one pints, of sea salt two pints, and of dried fish fifty; let these all macerate together, and afterwards be strained clear for use. All the *garums* were esteemed hot and drying by the ancients, and were sometimes given as laxatives before food. The modern writers understand the word *garum* in a much more limited sense, meaning no more by it than the brine or pickle in which herrings or anchovies are preserved.

GARTOPHYLLUS. See CLOVER-Tree.

GAS, in Chemistry, derived, according to Junker, from the German *gasch*, a *fresh* shalloon, and by Lavoisier, from the Dutch *gasch*, or German *gasch*, *spirit*, is a name given to the volatile invisible parts which escape from certain bodies, and which cannot be retained and collected, at least without great difficulty and mixture of other substances. The word is applied by Van Helmont to signify those elastic fluids which are invisible, and not condensable by cold; several of which he has described: such are the *gas vestivum*, or atmospheric air; *gas phlogiston*, or the fluid expelled during fermentations and effluvescences, called by later authors, *gas*, *factitious*, and *fixable* air; *gas pingue*, or the fluid extricated from inflammable substances during their analysis by heat; *gas flammum*, or the fluid produced in the delavation of nitre. He considers also, as so many kinds of *gas*, the noxious fluids which hover over the Gronte delle Cani in the kingdom of Naples, and at the bottom of mines and cellars, and that which arises in the burning of charcoal; the *gas* produced by the putrefaction of animal bodies; the matter which produces the plague; the *gas stras*, or arterial spirit of life; and his celebrated *acrius*. See AIR, fixable, &c. and DAMP. See an excellent treatise on the various kinds of *gas*, by the translation of Macquer's Dict. of Chemistry, published as an appendix to the last edition of that valuable work, 1777: in which treatise the ingenious author maintains, that most of the known *gas* consist principally of acid and phlogiston.

GASCOIGN, or **GASKOIGN**, the hinder thigh of a horse, commencing from the fluke, and reaching to the ply, or bending of the ham.

GASCOIGN,

GALICUM, or leucardie powder, in *Mellini*, is formed of the compound powder of crab's claws one pound, of original bezour prepared one ounce: this powder is made up into balls, called *Galican balls*, from the name of their inventor.

GASCONADE, a boast or vaunt of something very improbable.

The term has its rise from the Gascons, or people of Gascony, in France, who, it seems, have been distinguished for bragging and rhodomontado.

GASKETS, or gaskets, the small cord used to fasten the sails to the yards when futed up.

GAST house. See *Gaza House*.

GASTALDUS, or CASTALDUS, an officer anciently entertained in the courts of diverse princes.

The word is also written *gastaldus, gastaldus, gastaldus, gastaldus, &c.* *Mucet* derives it from the Arabic *chastaldus*, purveyor of a *hagis*, others from the German *gast*, and *haldus*, is *venue traveller*.

The *gastaldus* was what in Italy and Spain is now called *major domus*, viz. the master and steward of a household. The *gastaldus* was a comar, or count, which shews his office to have been very considerable.

In the laws of Italy, we sometimes also meet with *gastaldus* in the sense of a count, and sometimes as an ecclesiastical officer; so that it is somewhere expressed to be *simony* to buy the function of *gastaldus*.

GASTEROSTEUS, or Gasterostei, the name of a genus of the acanthopterygious fishes, the characters of which according to *Artedius*, are these: the branchiostegic membranes on each side contain three small and slender bones; the belly is almost all over covered with bony scales; the belly-fins have only two rays, the one of which is much larger than the other, and is prickly. The species of this fish are three. This is a genus of the *thoracici* of *Linnaeus*, who enumerates eleven species, distinguished by the number of back-fins.

The name is of Greek origin, and is derived from the words *γαστήρ*, the belly, and *ὀστέον*, a bone; the greater part of the belly of this fish being fortified by bony plates. See *STYCKEL's book*.

GASTREPILOICA, in Anatomy, a vein which opens into the trunk of the vena porta, formed of several branches, derived from the stomach and epiploon. Whence its name, from *γαστήρ*, stomach, and *epiploon*, epiploon.

GASTRIC, GASTRICUS, in Anatomy, is applied to divers veins, on account of their proceeding from the stomach or ventricle, which the Greeks call *γαστήρ*.

The *gastrica major*, or greater *gastrica* vein, is infused into the splenic vein; and the minor, or lesser *gastrica*, into the trunk of the vena porta.

GASTRIC is also applied to two arteries; one of which, called the *gastrica dextra*, or major, proceeds from the hepatic artery, and passing behind the pylorus, runs along the right side of the great curvature of the stomach, at last ends in the *gastrica sinistra*, or minor, which is a branch of the *splenic*, and runs from the left to the right, along the left portion of the great curvature of the stomach.

GASTRIC JUICE, a name given by some authors to the proper juice of the stomach. This is a thin, pellucid, spumous, and salubrious liquor, which continually diffuses from the glandular kernels of the stomach, for the dissolution, mixture, and dilution of our food, and is of great service in digestion.

GASTRILLOQUUS, or GASTRILLOQUOUS, a person who speaks inwardly, or within his stomach, and whose voice seems to come from afar off; more usually called *VENTRILLOQUUS*.

The term is formed of the Greek, *γαστήρ*, belly, stomach, and the Latin, *loqui*, is *spoke*.

GASTROCNEMIUS, from γαστήρ, and ἄστυς, the leg, in Anatomy, a name common to two muscles, constituting the *fura*, or calf of the leg; the one called *externus*, and the other *internus*. See *Tab. Anat. (Muscl.) fig. 6, 11, 21*.

GASTROCNEMIUS INTERNUS, called also *peroneus externus*, and *gastrocnemius*, has two distinct fleshy origins from the superior and hindermost part of each tubercle of the lower appendage of the thigh-bone, which in their descent, are each dilated into two small fleshy bellies, the innermost of which is thicker and larger, having each a different series of fleshy fibres, which at length uniting, make a broad, strong tendon; which, narrowing itself, joins the great tendon of the soleus, four fingers breadth above its insertion into the os calcis. See *Tab. Anat. (Muscl.) fig. 1. n. 66. fig. 2. n. 48*.

When this muscle acts, the foot is said to be extended, or pulled backwards; which motion is very necessary in walking, running, leaping, or standing on tip-toe, &c. Whence it is, that those who walk much, or carry heavy burdens, and who wear low-heeled shoes, have their muscles larger than others.

Vol. II. N° 148.

GASTROCNEMIUS, or peroneus internus, called also *soleus*, from its figure resembling a sole-shoe, is placed under the external. Its outer fleshy part is covered with a transparent tendinous expansion, which makes it appear of a livid colour. See *Tab. Anat. (Muscl.) fig. 1. n. 63. fig. 2. n. 47*.

It begins partly tendinous, chiefly from the hindermost part of the upper appendix of the fibula, and back part of the tibia, that is, below the insertion of the tuberosity; and increases to a large fleshy belly, composed of various orders of fleshy fibres, some of them underneath aply expelling the figure of the top of a feather, whose lamina, being base tendinous, join with the great tendon, which is about a finger's breadth long, and inserted into the superior and hindermost part of the os calcis.

The foot, together with the toes, being, as it were, a lever to the whole body, ought therefore to be attended with muscles of great strength to extend it, which is the reason that these muscles so much exceed their antagonists.

GASTROLATER, of γαστήρ, and λατρεύω, a glutton, or hippocrit, cuius domi venter est.

GASTROMANCY, or GASTROMASTIA, a kind of divination, practised among the ancients, by means of words coming, or seeming to come, out of the belly.

The word is Greek *γαστήρ*, belly, and *μαντεία*, divination.

There is another kind of divination, called by the same name *gastro-mancy*, which is performed by means of glasses, or other round, transparent vessels, within which certain figures appear by magic art. It is thus called, because the figures appear as in the belly of the vessel.

GASTROGRAPHY, in Surgery, expresses the operation of the future, or sewing up wounds in the abdomen.

The word is derived from *γαστήρ*, the belly, or abdomen, and *γράφω*, a *scribe*.

This operation is generally much decuded by the patient, and is unnecessary in several cases: 1. where the wound is only in the muscular part; and 2. where it is not very large, especially if it be made lengthways; for if the wound should penetrate into the cavity of the abdomen, and even let out a part of the omentum, or intestines; yet in cases where it is very small, as wounds generally are, which are made by puncture, or have happened lengthways; in these cases, upon retreating the parts which are pushed out, stopping the wound with a soft tent, and securing all with a proper bandage, it may be healed without the help of the needle. Besides, in fat persons, this operation is very difficult; and it would be an act of great cruelty in a surgeon, to perform this operation upon a man, when he might be cured after an easier method.

But there are two cases in which this operation is absolutely necessary: the first is, where the wound is so large, that there is no possibility of retaining the intestines by any other method; for as the intestines are continually pushed forward in the act of inspiration, by the action of the diaphragm and the abdomen, the falling down of the intestines, in this case, is unavoidable, and therefore the operation is necessary; the other is in large transverse wounds of the abdomen, where the muscles are divided, but the peritoneum is not concerned.

In wounds of the ABDOMEN, the chief enquiry is, whether the omentum or intestines are let out; if none of them have burst through the wound, the lips of the wound must be kept as close together as possible with the hands, and the patient kept with his head lying downwards, till the wound is sufficiently secured from letting out the contents of the abdomen: but when the intestines are already fallen out, they must be returned with the greatest expedition, lest they should receive any injury from the external air. It is said to be examined, however, whether they have received any wound or not, and whether they perceive their natural warmth and colour; for where they are cold, livid, or dry, or wounded, they are not to be returned suddenly, but softened with warm milk and water, or wrapped up for some time in the coat of some animal newly killed, till they have in some degree recovered their native warmth and condition.

You will easily perceive, that there is some hurt in the intestines, though the wound does not immediately appear; if there is more than ordinary fascicity in them; and when this is the case, the rest of the intestines must be pulled gently forward till you find the wound. If nothing of this sort is the case, but the intestines are in their natural state and condition, they must be returned in the following manner: the patient must be placed in a supine posture, and laid on that side that is opposite to the wound, and the intestine must be returned by the aperture of the wound with the two fore-fingers, taking

care never to take off one finger till the other is on the gut; the patient is to be assisted all the while to hold his breath, and the lips of the wound must be then brought together.

If the intestines have been forced through a small wound, and are afterwards to be defended with wind, that they cannot easily be returned, it is necessary to pull the intestine gently forward, that more of it may come out, and the wind take up by that means left-room in any one part; an assistant must then gently draw the wound as far as may be, either with his hand, or with two hooks fixed in the internal membrane; while the surgeon restores the intestines, when this is done, the wound must be fastened first with the hand, and then with the proper dressings; and in this case the surgeon may avoid the use of this painful operation.

When it is found necessary to perform this operation, it must be done in the following manner: first put a strong double or quadruple thread, well waxed, through two crooked needles, and with these stitch up both ends of the wound, beginning at one end with the upper lip of the wound, passing the needle through the peritoneum, muscles of the abdomen, and the common integuments, from within outwards, leaving only the breadth of a thumb between the stitches and the mouth of the wound, observing the same method in pulling the other needle through the lower lip; while you are pulling the needle with one hand, it will be proper to support the lips of the wound with the other, to prevent the intestines from being wounded. In a wound of two fingers breadth, one stitch in the middle will be sufficient; but in larger wounds, the stitches must be repeated in proportion to their size, leaving a thumb's breadth between each of the sutures; the extremities of the thread are to be left hanging down on each side; and when the suture is finished, while an assistant holds the lips of the wound together, these ends are to be tied in knots in the following manner: each end of the threads are to be taken up, and to be end first in a single, then in a slip knot, pulling a small holder between the two knots, to prevent the knot from being hurt. When there are more sutures than one, you must begin at the upper part of the wound, tying them down in order, that before the last is tied, a foot tent, of the size of a finger, with a thread fastened to the end of it may be introduced into the lower part of the wound. This tent will keep a passage open for the excretion of gross blood, or matter, which may be collected in the cavity of the abdomen. The wound, when all this is done, must be anointed with some vulnerary balsam, and covered with plaisters of lint, a flannel plaister and bolus, securing all with the respiratory bandage. Large wounds also extending to the peritoneum, but not penetrating it, require this operation to prevent bad symptoms, and dangerous hernia from a distention of the membrane; but in this case the needle must pass only through the muscles and common integuments. Heister's Surgery, book I. chap. 5.

GASTROTOMY, of *gaster*, and *tomy*, I cut, the operation of cutting open the belly; otherwise called the **CÆLIOTOMY**. See also **LITHOTOMY**.

GASULON, in the *Materia Medica*, a word used by Avicenna and Serapion, to express sometimes the plant hyssop, and sometimes lute. There are two very different things to be known under the same name; but the proper interpretation of the word being the *cleansing of cloths*, it was used probably at some time to signify every thing of an abstrusive quality; but among the many things of this kind once called by it, the two above mentioned are all that we had recorded, which may be easily distinguished by the context.

GATE, in *Architecture*, a large door, leading or giving entrance into a city, town, castle, palace, or other considerable building.

Thence, in Egypt, was anciently known by the appellation, *gate of the dead*. *Gate*, in Africa, has thirty-one gates. In ancient Rome there was a triumphal *gate*, *porta triumphalis*. In modern Rome there is the *Golden Gate*, which is only opened in the year of a grand jubilee.

The *gates* of London were many of them converted into gaols or prisons, as *Whitechapel*, &c. but they are now removed. The *gate*, or *by-gate*, are called *portuli*. *Gates* through which cranes, &c. are to pass, should not be less than four feet broad, nor more than twelve; the height to be 14 feet high.

GATE, or **GATT**, in the *Allegory*, called in French *traine*, is used for the going or pace of a horse.

GATE, in a military sense, is made of strong planks, with iron bars, to oppose an enemy. They are generally made in the middle of the earthen ramp, from whence they are fired, and defended by the two flanks of the battery. They should be covered with a good ravelin, that they may

not be seen or entailed by the enemy. These gates belonging to a fortified place, are passages through the rampart, which may be shut or opened by means of doors and a *portcullis*. They are either private or public.

Private gate are those passages by which the troops can go out of the town, unseen by the enemy, when they pass to and from the relief of the duty in the outworks, or on any other occasion which it is to be concealed from the besiegers.

Public gate are those passages through the middle of such cities, to which the great roads or public ways lead. The dimensions of these are usually about thirteen or fourteen feet high, and nine or ten feet wide, continued through the rampart, with proper recesses for foot passengers to stand in out of the way of wheel-carriages. The front of the *gate-way* on the outside is commonly ornamented with architecture either of the Tuscan or Doric order; and over the vault, which covers the passage, close to the town wall, is erected a building of about eighteen or twenty feet square, in which the portcullis is suspended; and on the inside of the rampart there is generally another building, of about a hundred feet in front, and thirty deep, and high enough to contain one or two floors of rooms for one of the town officers, the ground floor serving for guard-rooms for the troops on duty at the *gate*. See **HARROW**, **HERSE**, **GRAND**, and **PORTCULLIS**.

GATE, *gates*. See **SALLY-PORT**.

GATE of the *sea*, or a *passage*, is used when two ships lie abreast one another in a wave or blow, and by that means sometimes become *ribble*.

GATE, *opening of*, in *Allegory*. See **OPENING**.

GATHER, in the *Sea-language*. A ship is said to *gather* on another, when she gets the wind of her.

GATYSCHE, in *History*, a name given by some to an American fish, a species of the *tortosa* or *walleye*, of a yellow colour, and beautifully variegated with red, called by most authors by its Indian name, *fish* *orange*.

GAVALL, in the *Materia Medica*, a name given by some of the old writers to *scorbutum*, particularly to the Arabian kind, which was the purple, and was usually in form of small tears, and of a pale yellowish colour.

GAVEL, or **GABEL**, in *Law*, *quidam arbitri*, toll, estimate, yearly rent, payment, or revenue, of which there were anciently several kinds: *parsonage*, *quidam toll*, *quidam toll*, &c.

GAVEL is sometimes also used for what we more usually call the **GABLE**.

GAVELLET, **GAVELTUM**, in *Law*, a feudal and ancient kind of *exaction* used in Kent, where the custom of gavel-kind continues, whereby the tenant shall forfeit his lands and tenements to the lord, if he withhold from him his due rents and services.

The process of the *gavellet* is thus: the lord is first to seek by the view and of his court, from three weeks to three weeks, to find some default upon the tenant, till the fourth court; and if, at that time, he find none, at this fourth court it is awarded, that he take the tenement in his hand, in name of a default, and keep it a year and a day without manuring; within which time, if the tenant pays his arrears, and make reasonable amends for the withholding, he shall have and enjoy his tenement as before; if he come not before the year and day be past, the lord is to go to the next county court, with witnesses of what hath passed at his own court, and pronounce there his process to have farther witnesses; and then, by the award of his own court, he shall enter and manure the tenement as his own; so that, if the tenant desire afterwards to have and hold it as before, he must agree with the lord, according to this old saying: "has he not since any thing given, or any thing paid, then let him pay five pound for his wite, ere he become a headier again." Other copies have the latter part with some variations: "let him nine times pay, and nine times repay."

GAVELLET, in London, a writ used in the building of London. *Writ de gavellet in London. pro rebus suis, quia incunantur forent inordinabilibus*. And the Statute of *gavellet*, 10 Edw. II. gives this writ to lords of manors in the city of London, as well as in Kent. Here the parties, tenant and demandant, appear by *fores*, and to the cause why the lord should not have his *gavellet* again, on payment of his rent, or the other reason, the lands, on default thereof.

GAVELKIND, a tenure or custom, whereby the lands of the father are equally divided, at his death, among all his sons, or the land of the mother among all the brethren, if he have no issue of his own.

Lambard compounds this term of the three Saxon words *gylt*, *all*, *ten*, *omnibus cognationis proximis datus*. Verstegan calls it *gavelkind*, *quasi quicquid sit, i. e. to each child*

increased cylinder will be equal in content. The diameter of the inferior cylinder is the least diameter of the cask; the thickness of the cylindrical space is equal to the difference between the bung and head diameters. The only difficulty, therefore, lies in determining what portion of this difference must be added to the head diameter of the cask, in order to obtain the diameter of the mean cylinder, or the cylinder of equal content. Now experience shews, that if $\frac{1}{2}$ of the difference between the head and bung diameters of any cask be added to the head diameter, the cylinder whose diameter is equal to this sum, and whose length is equal to that of the cask, will contain as much or more than that cask, though the latter have the greatest degree of curvature that is ever given to them. And as the difference between the bung and head diameters of casks is seldom very great, the contents of a cask whose staves are quite straight from bung to head, or of a cask made up of two equal frustrums of two equal cones, will generally be nearly equal to the contents of a cylinder, whose diameter is equal to the sum of the head diameter of the cask, and a little more than half the difference between the bung and head diameters, and whose length is equal to the length of the cask. Therefore, all the varieties of which casks are capable lie between $\frac{1}{2}$ and $\frac{1}{3}$ of the difference between the bung and head diameters, and the former has only to take this part of this difference always between $\frac{1}{2}$ and $\frac{1}{3}$ at his judgment and experience inform him to be most suitable to the curvature of the cask; and this, added to the head diameter, gives the diameter of the mean cylinder.

It may not be amiss to note here, that the difference between the bung and head diameters may be very great, and yet the cask have no bulging at all, for the bulging is the bend, or curvature of the half staves between the bung and the head.

Mathematicians give us elaborate theorems, for computing the contents of casks, upon the supposed resemblance between the curvature of the cask and that of an ellipse, parabola, or hyperbola; but they may be as much mistaken in judging of the curvature, as an experienced cooper between $\frac{1}{2}$ and $\frac{1}{3}$ for after all, the contents of casks cannot be determined to a mathematical exactness; because the forms of casks do not exactly answer any mathematical figures. The business of measuring is at best but guess work; but it is such a way of guessing, as comes near enough the truth for the common purposes of life.

Here we may add such decimal multipliers, for the difference between bung and head diameters as have been found by experience to be the truest, and best suited to the several varieties or curvatures of casks.

First variety, or staves very much bulging, .70 or .695
Second variety, or staves not so much curved, .65 or .63
Third variety, or staves little less curved, .60 or .59
Fourth variety, or staves almost straight, .55 or .54

The following rule will serve for computing casks by the pen: take the difference of the bung and head diameters of any cask, and multiply that difference by the number which stands against the name of the cask given in the table; add the product to the head diameter; and the sum will be the diameter of a cylinder, which, being of the same length with the given cask, will contain as much; square the diameter thus found, and multiply that square by the length, and divide the product by 359 for beer gallons, and 594 for wine.

The multipliers for a cask, which is taken for varieties.

The middle { 2 of a spheroid } .70 great-ft bulge.
frustum { 1 of a paraboloid } .65 next less.
frustum { 3 of a cone } .55 next less to that.
4 of a cone } .54 next less to this.

Example. Let a cask be taken as the middle frustrum of a spheroid, the bung diameter of which is 32 inches, the head 26, and length 50 inches; what is the content in beer, and wine gallons? $32 - 26 = 6$. To which add $\frac{1}{2}$ of 6 we shall have 3.2 for the mean diameter, and $30.2^2 = 912.04$, which multiplied by the length 50 will give 45602, and $\frac{45602}{359} = 127$ beer gallons; and

$\frac{45602}{594} = 76.76$ wine gallons. The contents of other

casks may be found in the same manner by using the proper multipliers. Poil. Dict. Com. See EVYRANT'S ST. 10-ING 2nd.

For the ready computation of the contents of vessels, or of any solids in the measures in use in Great Britain, we shall here insert the following rules taken from a Treatise of Practical Geometry, published at Edinburgh in 1745. 8th. Vide pag. 137. 1st.

1st. To find the content of a cylindric vessel in English

wine gallons, the diameter of the base and height of the vessel being given in inches and decimals of an inch; square the number of inches in the diameter of the vessel; multiply this square by the number of inches in the height, then multiply this product by the decimal fraction .00034, and you will have the contents in the vessel in gallons, and decimals of a gallon. For example, let the diameter be $D = 31.7$ inches, the height $H = 65.3$ inches, then will the content be $DDH \times .00034 = 31.7 \times 31.7 \times 65.3 \times .00034 = 555.3754$ wine gallons.

2nd. Supposing the length of a gallon to contain 282 cubic inches, the content of a cylindric vessel is computed in each gallon, by multiplying the square of the diameter of the vessel by its height as before, and their product by the decimal fraction .00034, that is, the solid content in the gallons will be $DDH \times .00034$.

3rd. If the Scotch pint contain 10.4 cubic inches, the content of such a vessel in Scotch pints, will be $DDH \times .00056$.

4th. Supposing the Winchester bushel to contain 2178 cubic inches, the content of a cylindric vessel is computed in these bushels, by multiplying the square of the diameter of the vessel by its height, and the product by the decimal fraction .000236. But the legal Winchester bushel containing only 2150.38 cubic inches, the content of a cylindric vessel is computed in such bushels, by multiplying the square of the diameter by its height, and their product by the decimal .000232. Or the content will be $DDH \times .000232$. See HODGKIN.

5th. Supposing the Scotch wheat bushel to contain 21 Scotch pints, or about 2150 cubic inches, the content of a cylindric vessel in such bushels will be $DDH \times .00038$. And if the bushel contain 21 Scotch pints, the contents of such a vessel in bushels will be $DDH \times .000215$. See FIELDER.

6th. It is to be observed, that when the section of the vessel is not a circle, but an ellipse, the product of the greatest diameter by the least is to be substituted in these rules, for the square of the diameter.

7th. To compute the content of a vessel, which may be considered as the frustum of a cone in any of these measures. Let A represent the number of inches in the diameter of the greater base, B the number of inches in the diameter of the lesser base. Compute the square of A, the product of A by B, and the square of B. Take the third part of the sum of all three, and substitute it in the preceding rules for the square of the diameter, and proceed in all respects as before. Thus for example, the content in wine gallons will be $A^2 + A \cdot B + B^2 \times H \times .00012$. Or thus, to the square of half the sum of A and B add one third of the square of half their difference; and substitute this sum in the preceding rules for the square of the diameter of the base of the vessel. For the square of $\frac{1}{2}(A+B) = \frac{1}{4}(A+B)^2$; of the square of $\frac{1}{4}(A-B)$ gives $\frac{1}{4}A^2 + \frac{1}{4}AB + \frac{1}{4}AB + \frac{1}{4}B^2 = \frac{1}{4}A^2 + \frac{1}{2}AB + \frac{1}{4}B^2$.

8th. When the vessel is a frustrum of a parabolic conoid, measure the diameter of the section at the middle of the height of the frustrum; and the content will be the same as of a cylinder of this diameter, of the same height with the vessel.

9th. When a vessel is a frustrum of a sphere, if you measure the diameter of the section at the middle of the height of the frustrum, then compute the content of a cylinder of this diameter, and of the same height with the vessel, and from this subtract $\frac{1}{8}$ of the content of a cylinder of the same height, on a base, the diameter of which is equal to that height, the remainder will give the content of the vessel. That is, if D represent the diameter of the middle section, and H the height of the frustrum, you are to substitute $DD - \frac{1}{8}HH$ for the square of the diameter of the cylindric vessel in the first rule.

10th. When the vessel is a frustrum of a spheroid, if the bases are equal, the content is readily found by the rule given from Oughtred. In other cases, let the vertex of the solid be to the conjugate axis, as a to b ; let D be the diameter of the middle section of the frustrum; let the height or length of the frustrum, and substitute in the first rule $DD - \frac{1}{8}HH$ for the square of the diameter of the vessel.

11th. When the vessel is a hyperbolic conoid, or the axis of the solid be to the conjugate axis as a to b , the diameter of the section at the middle of the frustrum, D, the height or length, compute $DD + \frac{1}{8}HH$, and substitute this sum for the square of the diameter of the cylindric vessel in the first rule.

12th. In general, it is used to measure any round vessel distinguishing it into several frustrums, and taking the

diameter of the section at the middle of each frustum; thence to compute the content of each, as if it was a cylinder of the mean diameter; and to give their sum as the content of the vessel. From the total content computed in this manner they subtract successively the numbers which express the circular areas that correspond to those mean diameters, each as often as there are inches in the altitude of the frustum to which it belongs, beginning with the uppermost; and in this manner calculate a table for the vessel, by which it readily appears how much liquor is at any time contained in it, by taking either the dry, or the wet inches; having regard to the inclination, or drip of the vessel, if it has any.

This method of computing the content of a frustum from the diameter of the section at the middle of its height, is exact in that case only when it is a portion of a parabolic conoid; but in such vessels as are in common use the error is not considerable. When the vessel is a portion of a cone or hyperbolic conoid, the content by this method is found less than the truth; but when it is a portion of a sphere or spheroid, the content computed in this manner exceeds the truth. The difference or error is always the same in the different parts of the frustum, or of similar vessels, when the altitude of the frustum is given. And when the altitudes are different, the error is in the triplicate ratio of the altitude. If exactness be required, the error in measuring the frustum of a conical vessel, in this manner, is $\frac{1}{2}$ of the content of a cone, similar to the vessel, of an altitude equal to the height of the frustum. In a sphere it is $\frac{1}{2}$ of a cylinder, of a diameter and height equal to the frustum. In the spheroid and hyperbolic conoid, it is the same as in a cone, generated by the right-angled triangle contained by the two femurs of the figure revolving about that side which is the femur of the frustum. These are demonstrated in a treatise of fluxions by Mr. Mac Laurin, where those theorems are extended to frustums that are bounded by planes oblique to the axis in all the solids, that are generated by any conic section revolving about either axis. Vide p. 25. and 75.

In the usual method of computing a table for a vessel, by subtracting from the whole content the number that expresses the uppermost frustum, as often as there are inches in the uppermost frustum, and afterwards the numbers for the other areas successively, it is obvious that the contents assigned by the table, when a few of the uppermost inches are dry, are stated a little too high, if the vessel stands on its lesser side, but too low when it stands on its greater base, because, when one inch is dry, for example, it is not the area at the middle of the uppermost frustum, but rather the area at the middle of the uppermost inch, that ought to be subtracted from the total content, in order to find the content in this case.

But gauging, as now practised, is chiefly done by means of instruments called *gauging-rods*, or *rules*, which do the business at once, and answer the question without so much calculation; which is no inconsiderable addition, both to the ease and dispatch of the work. This instrumental way of gauging, therefore, we shall here chiefly inquisition.

Construction of a GAUGING-rod, whereby the content of any cylindrical, or conical vessel, is easily had. Take the diameter AB of a cylindrical vessel, ABDE, Tab. Surveying, fig. 21, that holds one of the measures wherein the fluid is estimated, e. g. gallons, and join it at right angles to the indefinite line A 7. From A to 1, set off a right line equal to AB; then will B 1 be the diameter of a vessel, that holds two measures, or gallons, of the same height as the former.

Again, let A 2 = B 1, then will B 2 be the diameter of a vessel that holds three measures, but of the same height as that which only holds one. And, after the same manner, find the diameter of other large vessels, B 3, B 4, B 5, B 6, B 7, &c.

Lastly, let off the several divisions thus found, A 1, A 2, A 3, &c. upon the side of a rod or rule; and, on the other, the height or depth of a cylinder, that holds one measure or gallon, repeated as oft as it will go. Thus is the *gauging-rod* complete.

For cylinders, that have the same altitude, are to each other as the squares of their diameters; consequently the square of the diameter of the vessel that holds 2, 3, or 4 gallons, must be double, triple, or quadruple of that which only holds one. And since in the first, AB = A 1, the square of B 1 is double, that of B 2 triple, that of B 3 quadruple, &c. it is evident, that the right lines A 2, A 3, A 4, &c. are the diameters of the vessels required.

These divisions, therefore, being applied to the side of a cylindrical vessel, it will immediately appear how many measures, e. g. gallons, a cylindrical vessel of that base, and of the height of that which holds one gallon, will contain.

VOL. II. N° 148.

Wherefore, finding by the divisions on the other side of the rod, how often the height of one gallon is contained in the height of the given vessel; and multiplying the diameter before found by this number, the product will be the number of gallons the vessel contains.

Thus, e. g. if the diameter of the cylindrical vessel be 8, and its height 12, its contents will be 96 gallons.

Note, 1^o. The less you take the height of the cylinder containing one gallon, the greater will the diameter of the base be: whence both that, and the diameters of the cylinders containing several gallons, will be the more easily divisible into lesser parts. Beyer directs such heights to be only one digit, or tenth of an inch.

2^o. The diameters of vessels holding one or more decimal parts of a gallon will be had, by dividing one or more decimal parts of the vessel holding a whole gallon, by its height; which gives us the area of the circular base; from whence the diameter is easily found by the rules delivered under DIAMETER, CIRCLES, &c. And after the same manner, the diameters are found for the divisions of vessels, that hold two or more gallons.

GAUGING-rod, use of the. To find the content of a cask; that is, to determine the number of measures, e. g. gallons, it will hold: apply the *gauging-rod* to the vessel, as directed in the preceding article, and find both the length of the cask, A C, fig. 12, and both diameters, G H, and A B. Now, as we find, by experiment, how far sooner it may be from geometrical exactness, than a common cask of this form may safely enough be reputed as a cylinder, whose base is a medium between the head and the belly; find such medium, which call the *equated diameter*.

Then multiplying the number thus found by the length of the cask A C, the product will be the number of measures the vessel contains.

Suppose, e. g. AB = 8, and GH = 12, and AC = 15, the equated diameter will be 10, which multiplied by 15, gives the capacity of a cask, 150 measures.

If it happen, that the diameters of the two ends be not equal, measure them both, and take half their sum for the diameter to work by.

There is another method whereby the content of a vessel is had, without any calculation at all, which obtains in divers parts of Germany and the Low-Countries: but as this supposes all vessels to be similar to each other, and their length double of the equated diameter, that is, of half the sum of the diameters AB, and GH, it is not safe to use it in all places. Kreyer, however, prefers it so much before all others, as including all the precautions possible, that he recommends it to the public, to enact it by law, that all casks be made in this proportion.

The methods of gauging, which chiefly obtain among us, are, by the four-foot *gauging-rod*, and Everard's *sliding-rule*.

GAUGING-rod, description and use of the four-foot. The four-foot *gauging-rod*, represented in Tab. II. Surveying, fig. 20, is usually made of box, and consists of four rules each a foot long, and about three-eighths of an inch square, joined together by three brass joints; by which means the rod is rendered four feet long, when the four rules are quite open, and but one foot when they are all folded together.

On the first face of this rod, marked A, are placed two diagonal lines; one for beer, and the other for wine; by means of which the content of any common vessel in beer or wine gallons may be readily found, by putting the rod in at the bung-hole of the vessel, till it meets the intersection of the head of the vessel with the staves opposite to the bung-hole. For distinction of this line, there is written thereon, *beer and wine gallons*.

On the second face, 5, are a line of inches, and the gauge-line; which is a line expressing the areas of circles, whose diameters are the correspondent inches in ale gallons. At the beginning is written, *ale area*.

On the third face, 6, are three faces of lines; the first, at the end of which is written *length*, is for finding how many gallons there are in a *length*, when it is not full, lying with its axis parallel to the horizon. The second line, at the end of which is written *B. L.* signifying a *bottling*, is for the same use as that for the *length*. The third line is to find how much liquor is wanting to fill up a butt when it is *banding*; at the end of it is written *B. S.* signifying a *bottling standing*. In the half of the fourth face of the *gauging-rod*, 7, there are three scales of lines, to find the wants in a *gill*, *kilderkin*, and barrel, lying with their axes parallel to the horizon. They are distinguished by letters F. G. B. signifying a *fist*, *kilderkin*, and *barrel*.

GAUGING-rod, use of the diagonal lines on the. To find the content of a vessel in beer or wine gallons, put the brass end of the *gauging-rod* into the bung-hole of the cask, with the diagonal lines upwards, and thrust this brass

end to the meeting of the head and flaves; then with chalk, make a mark at the middle of the bung-hole of the vessel, and also on the diagonal line of the rod, right against, over one another, when the brail end is thrust home to the head and flaves; then turn the bung-stem to the other end of the vessel, and thrust the brail end home to the end, as before.

Lastly, for if the mark made on the gauge-rod come even with the mark made on the bung-hole, when the rod was thrust to the other end; which if it be, the mark made on the diagonal lines, will, on the same lines, show the whole content of the cask in beer or wine gallons.

If the mark made on the bung-hole be not right against that made on the rod, when you put it in the other way, then, right against the mark made on the bung-hole, make another on the diagonal lines; and the division on the diagonal line, between the two chalks, will show the vessel's whole content in beer or wine gallons.

Thus, e. g. If the diagonal line of a vessel be 48 inches four tenths, its content in beer gallons will be near 57, and in wine gallons 62.

If a vessel be open, as a half-barrel, tun, or copper, and the measure from the middle on one side, to the head and flaves be 38 inches, the diagonal line gives 122 beer gallons; half of which, viz. 61, is the content of the open half tub.

If you have a large vessel, as a tun or copper, and the diagonal line, taken by a long rule, proves 70 inches; the content of that vessel may be found thus:

Every inch, at the beginning-end of the diagonal line, will ten inches. Thus ten inches becomes 100 inches; and every tenth of a gallon will 100 gallons; and every whole gallon will 1000 gallons.

Exam. at 44.8 inches, on the diagonal line, is 200 gallons; to that 4 inches 48 parts, now called 42 inches 8 tenths, is just two-thirds of a gallon, now called 200 gallons; to also, if the diagonal line be 76 inches and 7 tenths, a cask cask, of such diagonal, will hold a 1000 beer gallons; but an open cask but half so much, viz. 500 beer gallons.

GAVIGATION, use of. To find the content of any cylindrical vessel in ale gallons; seek the diameter of the vessel in inches, and, just against it, on the gauge-line, in the quantity of ale gallons contained in one inch deep; this, multiplied by the length of the cylinder, will give its content in ale gallons.

For example, suppose the length of the vessel 32.00, and the diameter of its base 25 inches; to find what is the content in ale gallons?

Right against 25 inches, on the gauge-line, is one gallon, and 745 of a gallon; which multiplied by 32.00, the length, gives 35,944 gallons for the content of the vessel.

The bung diameter of a hoghead being 25 inches, the head diameter 22 inches, and the length 32.00 inches; to find the quantity of ale gallons contained in it?

Seek 25, the bung diameter, on the line of inches; and right against it, on the gauge-line, you will find 1,745; take one third of it, which is 580, and set it down twice; seek 22 inches in the head diameter, and against it you will find, on the gauge-line, 1,350; one-third of which added to twice 580, gives 1,660; which multiplied by the length 32.00, the product will be 53,032, the content in ale gallons.

Note, this operation supposes, that the aforesaid hoghead is in the figure of the middle frustum of a spheroid.

The use of the lines on the two other faces of the rod, is very easy; you need only put it downright into the bung-hole (if the vessel you desire to know the quantity of ale gallons contained therein be lying) to the opposite flaves; and then where the surface of the liquor cuts any one of the lines appropriated to that vessel, will be the number of gallons contained in that vessel.

The description and use of Everard's sliding-rule for gauging, see under SLIDING-RULE.

GAVIAON, in Ornithology, the name by which the Portuguese called the *CAKACARA*, a species of Brazilian hawk, of the genus of *one line*.

GAVILAN, in Natural History, a name given by the Spaniards to a species of hawk, common in the Philippine Islands; it is somewhat larger than our sparrow-hawk, and is of a yellowish colour on the back and wings, and whitish under the belly; it is the most common of all the birds of prey in that part of the world, and is very voracious, and mischievous.

GAVIOTA, in Ornithology, the name given by the Portuguese to a water-fowl of the gull kind, common in Brazil, and called by the natives *ganga ganga*. It is of the size of a common hen; its beak is long, stout, and yellow; its head is black on the top, as also the further half of the wings and till the throat, breast, and belly

are white; it lays in the sand, and its eggs are of the size of those of the hen, and are accounted very good, but the flesh is not valued.

GAULISH language. See ROMAN, and PERSIAN.

GAULONITA, among the Jews, the name of a religious sect, rather than a religious sect, the same with the *GALILEANS*.

GAULTHERIA, in Botany, a genus of the *diandra* class; the exterior calyx is double-leaved, the interior is divided into five segments; the corolla is ovate; the nectarium has ten sharp points; and the fruit is a five-celled capsule. There is one species.

GAULUS, in Antiquity, a ship of a roundish form, mostly used by the people of Phoenicia.

GAULUS also signified a kind of cap.

GAUNT, an old word for lean, or lank. Thus, we say, a gaunt bellied, or light-bellied horse, when his belly shrinks up towards his flanks.

GAUNTLET. See GANTLET.

GAVOTTA, or GAVOTTE, derived from the *Gavotti*, a people inhabiting a mountainous district in France, called *Gap*, in *Italian Alps*, is a kind of dance, the air whereof has two strains, brisk and lively, and in common time; each of its strains is played twice over, the first has usually four or eight bars, and the second contains eight, twelve, or more. The time begins with a minuet, or two crotchets, or notes of equal value, and the hand rising; and ends with the fall of the hand upon the dominant, or mediant of the mode, never upon the final, unless it be a minuet. And the last begins with the note of the hand, and ends with the fall upon the final of the mode.

The *Gavotte* of Corelli, Albini, Vivaldi and others of the Italians, correspond with these rules as far as they relate to the measure, the number of bars in each strain, and the cadences; but in respect to the initial notes of the air they deviate from it; for they sometimes begin with a whole note, and sometimes with an odd quaver.

GAVOTTA, tempo di, in the *Italian Alps*, is when only the time or movement of *gavotte* is intoned, without any regard had to the measure or number of bars, or strains. We often find parts of fountains, which have this phrase to regulate their motion.

GAURA, in Botany, a genus of the *monogynia* class; the calyx is tubulous and divided into four segments; the corolla consists of four petals; and the fruit is a quadrangular nut, containing a single seed. There is one species.

GAURES, or rather GABRIEL, or GABRIEL. See GABRIEL.

GAUSE, or GAUSE, in Commerce, a very thin, light, transparent kind of silk, when sometimes of silk, and sometimes only of straw.

To wrap the silk for making of *gauze*, they use a peculiar kind of mill, upon which the silk is wound; this mill is a wooden machine, about six feet high, having an axis perpendicularly placed in the middle thereof, with six large wings, on which the silk is wound from off the bobbins, by the axis turning round.

When all the silk is on the mill, they use another instrument to wind it off again on two beams; this done, the silk is pulled through as many little beads as there are threads of silk; and thus rolled on another beam, to supply the looms.

The *gauze-loom* is much like that of the common weavers, though it has several appendages peculiar thereto. See LOOM.

There are figured *gauzes*; some with flowers of gold and silver, on a silk ground; these last are chiefly brought from China.

GAYAC. See GUAIACUM.

GAYTICUCA, in Zoology, the name of an American species of serpent, found as it is said only in the kingdom of Mexico. It grows to a vast size, and thinks to intolerably, that no creature can bear to be near it.

GAZA girana, in Ornithology, the name of a small species of dove, of a fine white colour, called by other authors *ardua alta minor*, or the *small white dove*. It is so small as not to weigh a pound. Its whole body is of a pure and perfect snow-white, and it has a short crest on the hinder part of its head, and a naked space where it greets about its eyes. Its feet also are green, and its sometimes covered with blackish scales. The feathers of the crest are very soft and white, and are much valued. It is seen in Venice and Italy, and is common enough in the markets there. The crest feathers, when they are usually pulled off before it is offered to eat.

GAZAR, a name used by some authors for the bay-tree. See JOHNSTON.

GAZE-band. See HOUND.

GAZELLA, GAZELLE, or ANTELOPE, is a species of the *ovis*, or GOAT, in the Linnaean system; others have made it a distinct genus, with annulated, or spotted horns, eight broad cutting teeth in the lower jaw, and body

body and limbs of a light and elegant form. Thus, they make it an intermediate genus between the GOAT and DEER, agreeing with the first in the texture of their horns, which have a core in them, and they never call them, and with the last in the elegance of their form and great swiftness. The activity and speed of this animal are surprising, so that the chase of it is a favourite diversion to the eastern nations. Some species of the antelope form herds of two or three thousand, while others keep in small troops of five or six. There are several species and varieties of this animal, which, excepting two or three, inhabit the hottest part of the globe. Their proper climates seem to be those of Asia and Africa, where they are very numerous. See ANTELOPE. Vol. II. *Zooaphia*, No. 121. which represents the white-footed gazelle, or antelope of India, with short horns bending a little forward large ears, marked with two black stripes; a small black mane on the neck and half-way down the back; a tuft of long black hairs on the fore-part of the neck; above that a large foot of white; another between the fore-legs on the chest; one white spot on each fore-foot; two on each hind foot; long tail tufted with black hairs to the height, to the top of the shoulder, about four feet, and the colour a dark grey. The female is of a pale brown colour, without horns, and having on each foot three transverse bands of black, and two of white. Pennant's Syn. of Quadr. p. 29.

GAZZETTE, a news-paper, or printed account of the transactions of divers countries, in a loose sheet or half-sheet.

The word is formed from *gazetta*, a kind of coin, formerly current at Venice, which was the ordinary price of the first news-paper printed there: though others derive it, by corruption, from the Hebrew *gazat*, which signifies, news, a messenger; but this etymology is too much forced.

Gazettes, which most people look on as trifles, are by some held the most difficult kind of composition that have appeared. They require a very extensive acquaintance with the languages, and all the terms thereof, and a great facility and command of writing, and of relating with perspicuity, and in few words.

To write a *gazette*, a man should be able to speak of war both by land and sea; be thoroughly acquainted with every thing relating to geography, the history of the times, and that of the noble families; with the several interests of princes, the secrets of courts, and the manners and customs of all nations.

Vignol de Marville recommends a set of *gazettes*, well written, as the best books for the instruction of young persons coming into the world.

The first *gazette* published in these parts, is said to have been that of Paris, begun in the year 1661, by Theophrastus Renaudot, a physician of Montpellier, in his office of intelligence.

GAZZERA, extraordinary. See EXTRAORDINARY.

GAZZONS, in *Pastorals*, tufts, or pieces of fresh earth covered with grass, cut in form of a wedge, about a foot long, and half a foot thick, to line or face the outside of works made of earth, in order to keep up the same, and prevent their mouldering.

GAZZOPHYLIUM, in the *Jewish Antiquities*, according to the Greek etymology of *gaza*, treasure, and *phylion*, I keep, signifies the treasury-chamber. There were several places in the temple of Jerusalem, where the rich presents consecrated to God by kings, princes, or private persons were kept. But the signification of this word *gazzophylum*, has been further enlarged, so as to comprehend the rooms where the provisions of the temple were laid up, both for sacrifices, and for the support and subsistence of the priests, and in general this word is used for all the apartments of the temple. In the Gospel, by *gazzophylum* is meant the chest into which people cast their offerings at the entrance of the temple. It has been also used by naturalists for a collection of figures of curious subjects. Mark xii. 41, 43 Luke xxi. 1. Calm. Dict. Bibl.

GAZZOPHYLAX, *Γαζοφυλάξ*, in *Antiquity*, an officer who had the care and management of the treasure belonging to the kings of Persia.

GAZZA, in *Ornithology*, the name of a species of *heron* common in Italy, and called by many authors *ardea alba*, *ardea*, the *greater white heron*. In whole body it is of a dove white, its beak yellow, and the membranes about its eyes green; though called large in comparison of the lesser white one, it is smaller than the common grey heron. Its tail also is much longer, and it has no crest. It is sometimes seen in England, and has been mistaken for a common heron, become accidentally white, as sparrows and other birds sometimes are.

GAZZETTA, in *Ornithology*, a name given by Gmelin

and others to a species of small white heron, sold in the markets of Italy, and seeming to be the *ardea alba minor* of authors, or *GARA GIOVARE* of the Venetians.

GAZZETTO, in *librery*, the name of a fish of the *TERNI*, or *verat* kind, caught in the Mediterranean, and sold in the markets of Italy. It is of a fine green colour, and is considerably thick, though broad; its fins are spotted, and it has a large purple tubercle near the anus. It has orange back, fins which has twenty-four ribs or rays, the first fifteen of which are rigid and thick, the rest smooth and flexible.

GLANNIDES, in *Natural History*, a name given by some authors to the stone called by others *encymitus*. It seems to have been the same with our forty incrustations on the tops of crabs, &c. but the word has been generally understood to mean the eagle stone. It was supposed to possess great virtues in helping delivery, and was given to women in their labours.

GEAR, or *about year*, *GEAR*, at sea, a command to work on all hands.

GEASTER, of *ye earth*, and *yea*, *fast*, in *History*, the name of a genus of funguses, or according to Linnaeus, of some species of the genus of the *LYCORHIZON*. These funguses have a rounded bottom like a flat, and in the centre of this there grows a round ball which opens at the top when ripe, and is found to be full of impenetrable seeds in form of powder. See a description and drawing of this plant by Dr. Watson, in Phil. Trans. vol. xliii. p. 334.

GECCO, in *Natural History*, a name given by the Indians to their terrible poison, which kills in ever so small a quantity when mixed with the blood. They say that this *gecco*, is a venomous fish or humour, vomited out of the mouths of their most poisonous serpents, which they procure in this fatal strength, by hanging up the creatures by the tails, and whipping them to enrage them: they collect this in proper vessels as it falls, and when they would use it, they utter poison a weapon with it, or wounding any part of the flesh, introduce the smallest quantity imaginable of it, and this is said to be immediate death.

GECHYTON, of *ye earth*, and *yea*, *I spread*, a name given by some authors to the external covering of the earth, commonly called garden mould, which is soft and not stony.

GECOLITHUS, a corrupt way of spelling the word *testator*, the name of the lapis judicatus among the Romans. The writers of the middle ages often write it *gcolithus*.

GED, in *Ornithology*, an English name for the small species of snipe, usually called the *JAUNCE*, and by authors *GALLINAGO MINOR*.

GERAS, a general term for trappings, harness, and all other things that belong to draught-horses or oxen. *Gerat*, in a *dog*. See *GERAT*.

GEGENE, *Γεγεννη*, in *Asiatick*. The ancients generally called themselves *Γεγεννη* *sons of the earth*, as Hesiodus informs us. Alluding to the same original, the Alchemists sometimes styled themselves *Τριβλη γεγεννη*, and some of them were geographers, or poets, faltered to their hair at badges of honour, to distinguish them from others of less antiquity, and less noble extraction, because those infants were believed to be generated out of the ground. Pott. Archæol. Græc. lib. i. cap. 6.

GEHENNA, *Γεεννα*, a scripture term, which has given some pain to the critics. It occurs in St. Matthew v. 22. 29. 30. x. 28. xlvii. 7. xlviii. 15. 33. Mark ix. 43. 45. 47. Luke xii. 35. James iii. 6.

The authors of the *Lexicon* and *Geneva* versions retain the word *gehenna*, as it stands in the Greek, the like does M. Simon: the English translators render it by *hell* and *hell-fire*, and the like do the translators of *Moses*, and other Bibles.

The word is formed from the Hebrew *gehinnom*, i. e. valley of Hinnom. In that valley, which was near Jerusalem, there was a place named *Tophet*, where some Jews sacrificed their children to Moloch, by making them pass through the fire. King Josiah, to render this place for ever abominable, made a canal or common sewer thereof, where all the filth and excrement in the city were cast.

The Jews observe farther, that there was a continual fire kept up there, to burn and consume those creatures for which reason, as they had no proper term in their language to signify *hell*, they made use of that of *gehenna*, or *gehinnom*, to denote a fire unextinguishable.

GEISON. See *GEISON*.

GELÆOPACHIA, in *Natural History*, the name of a class of mineral stony, which are inflammable, and of somewhat thick texture, and opaque. The word is derived from the Greek *gela*, the earth, stony oil, and *opachia*, thick. The bodies of this class are the bitumens, tar, oil of earth, and the

the common phisphaturn of the Gops, which see under their several heads.

GELFOPSILLA, in *Natural History*, the name of a class of fossils. The word is derived from the Greek *gelos*, earth, *psilla*, and *psos*, thin, and expresses a thin, oily substance naturally found in the earth. These are thin and pellucid inflammable liquid substances, commonly known by the name of liquid bitumens, but by that denomination confounded with the thicker and coarser kinds. The only bodies of this class are those commonly distinguished by the names of **NAPHTHA**, and **PETROLEUM**.

GELASIAN calendar. See **CALENDAR**.

GELASIAN dento, a term used by some authors to express the four middle lower teeth, bulk of the upper and under jaw. They have their name from the Greek *gelos*, laughter, because they are shown when people laugh.

GELATINA. See **JELLY**.

GELATINOUS, among the *Physicians*, is applied to any thing approaching the glutinous consistence of a jelly. **GELATIO**, properly signifies freezing, but is also used for that rigidity of the body and limbs, which comes on in the cataplexis, and other disorders of that kind.

GELDUM, a name given by the Hungarian miners to a sort of marcasite or mundic, which contains a considerable quantity of silver.

GELD, or **GILD**, in our *Ancient Customs, a mould, or compensation for a crime or delinquency. See **GILD**. Hence *wereld* was anciently used for the value or price of a man slain, and *gryld*, of a beast, &c.*

See *the names of Geldin, & Dangelin, Hangelin, & Fangelin, & de Blodwin, & Fimwin, & Leirwin, & Hingwin, & Frowin, & Werdwin, & Jowwin, & Hoozwin, & Tellingwin.* Charta Ric. II. Priorat. de Hatt. lund. in Devon.

GELD feet, **GELD horns**, and **GELD wood**, see the substantives.

GELDABLE. See **GILDABLE**.

GELDER-rose, in *Botany*. For the character, see **WAY-faring-rose**.

The common marsh elder, which grows naturally in marshy grounds, and on the sides of rivers in many parts of England, is not often kept in gardens: it is called by some the *golden-rose*, with flat flowers, to distinguish it from the other, whose flowers are globular. The marsh elder is the original species, and the *golden-rose* is a variety which accidentally arose from it. The former has a border of male flowers, which are large, and the middle of the umbel is composed of hermaphrodite flowers, which are succeeded by oval, red berries: the latter has all male flowers, of the same size and shape with those of the border of the first, so that they swell out into a round figure, which has occasioned some country people giving it the name of *foam-ball tree*. This sort is cultivated in gardens for the beauty of the flowers, which make a fine appearance during their continuance.

It will rise to the height of eighteen or twenty feet, if permitted to stand. The stem becomes large, woody, and hard; the branches come out copiose, and are apt to grow irregular; they have a grey bark. The leaves are placed opposite; they are divided into three or four lobes, somewhat like those of the maple; the flowers come out at the ends of the branches; those of the first in large umbels, and those of the second in a corymbus; they are very white, and appear the beginning of June. Those of the first have oval berries succeeding the hermaphrodite flowers, which turn of a scarlet colour when ripe, but the other having only male flowers are barren.

The common *golden-rose* sends out plenty of suckers from the roots, by which it is frequently propagated; but as the plants so raised are very apt to put out suckers, they are not so good as those which come from layers or cuttings; both sorts love a moist soil. They are very hardy, and will thrive in the coldest situations, but not within the spray of the sea. The common *golden-rose* is seldom suffered to stand very long in gardens; but one has been seen whose stem was more than two feet and a half round.

GELDING, the operation of castrating, and particularly horses.

In *gelling* of horses, regard is to be had to their age, the season of the year, and, as the farmers say, to the state of the moon. For the first, if it be a cold, the operation may be started at nine, or at fifteen days old, if the testicles be come down, because the sooner he is gelded, the better it will be for his growth, shape, and courage; though a horse may be gelded at any age, if care be taken in the cure. As for the second, the best time is about April or May, or else about the latter end of September; and in the third, the wane of the moon is preferred as the fittest time.

The manner of *gelling* is thus: the beast being call on

some fast place, the operator takes the testicles between his fore and great finger; dists the cord, and presses out the stones; then taking a pair of nippers made very smooth, either of steel, box, or brass, he claps the strings of the stones between them, very near to where the stones are set on, and presses them to hard, that there may be no flux of the blood, and then tears away the stone with a thin cauterizing iron, made red-hot. This done, he takes a hard phlegm, made of wax, resin, and washed turpentine, melted together, and melts it on the head of the string with the hot iron, and afterwards tears the string, and melts more of the flux, till there is a good thickness of the same laid on the string.

This being done to the stone, the nippers are loosened, and the like is done to the other; and the two fins of the cord are then filled with white salt, and the outside of the cord anointed with hog's grease; and thus they let him live, and keep him in a warm stable, without tying him up.

If he swells much in his cord or sheath, they chase him up and down, and make him trot an hour in a day, and he soon recovers. See **CASTRATION** and **EMUCO**. **GELDRIO**, in the *Manga*, is also used for a horse, whose testicles are cut out.

GELDUM, a name given by some to the philosopher's stone.

GELFUM, or **GELVUM**, an Hungarian name for a kind of mundic, which contains silver.

GELLOSIA, in *Natural History*, a name by which some of the writers of the middle ages call the **CHALAZIAE**.

GELLOSCOPY, **GELLOSCOPIC**, of *gelos*, laughter, and *scopia*, I consider, a kind of divination, drawn from laughter; or a knowledge of any person's character and qualities, acquired from the consideration of his laughter.

GEM, or **GEMM**, **GEMMA**, a common name for all precious stones or jewels; consisting of the siliceous, or what is improperly called vitrifiable earth, much valued for their lustre, transparency, colour, hardness, weight, and rarity. These are diamonds, rubies, sapphires, topazes, emeralds, chrysolites, amethysts, garnets, hyacinths or jacinths, beryls or aqua marina; the order in which they are enumerated shews their relative degree of hardness.

Dr. Hill distributes *gemm* into two classes; viz. the pellucid *gemm*, which are bright, elegant, and beautiful *crystals*, always found in small masses, extremely hard, of great lustre, composed of a very firm and pure substance, giving fire with steel, not fermenting with acid menstrua, and calcinable in the fire with great difficulty; of which there are two genera, the **CHRYSALISMA**, and the **CHRYSALISMA**; and the semi-pellucid *gemm*, which are defined to be stones, composed of a but slightly defecated crystalline matter, of great beauty and hardness, of a moderate degree of transparency, and usually found in small masses. The bodies of this class are divided into two general orders, and under these into eight distinct genera. Of the first order are those of but few variations, and frequently of one plain simple colour, though sometimes veined. Of the second are those remarkable for their veins, zones, and variegations. The genera of the first order are the corneals, chalcedonies, hydropic, and prismatic. Those of the second, are the agates, onyxes, sardonyxes, and carnelians. See each of these under its proper head.

Others distinguish precious stones into three kinds:

1. Such as are entirely transparent; which again may be divided into such as are either colourless, as the diamond, or coloured, as the emerald, ruby, &c. Which division of coloured *gemm* may be subdivided into those of one colour, as the rubies, and those with several, as the opals.

2. Brilliant, or shining, but less transparent, as the *Bellonius gemm*.

3. Semi-transparent, as the *onyx*.

Bishop Wilkins divides precious stones into *more* and *less transparent*.

The *less transparent* he distinguishes by their colours; into red, as the sardius and cornelian; pale fleshy colour, like that of a man's nail, as the onyx; bluish, as the turquoise; and those of various colours, as opal and cat's eye.

The *more transparent* he distinguishes into such as are colourless, as the diamond and white sapphire; and coloured, which are either red, as the ruby, carbuncle, and garnet; yellow, as the chrysolite and topaz; green, as the emerald, smaragd, and beryl; bluish, as the sapphire; and purple or violaceous, as the amethyst.

Dr. Woodward divides precious stones somewhat more precisely, into *opaque*, *semi-opaque*, and *transparent*.

The *opaque* are either of one colour, as the turquoise, or of various colours, as the lapis lazuli, and jasper.

Semi-opaque either have their colours permanent, as the agate, chalcedony,

chalcidony, onyx, fardony, cornelian, and beryl; or their colours vary according to the position of the light, as in the *oculus cati*, &c. &c.

Transparent stones are either *with colour*, as the topaz and hyacinth, *yellow*, for example; or *without colour*, as the ruby, and amethyst, red, *lapis lazuli*, sapphire, and aquamarine, blue, and emerald, green, &c. &c. or *partaking thereof*, or *without colour*, as the crystal, picro-diamond, white sapphire, and diamond.

The natural history, characteristic properties, &c. of each stone, for under DIAMOND, CORNELIAN, RUBY, TURQUOISE, ONYX, EMERALD, CHRYSOMEL, &c. For the medicinal virtues of *precious stones*, or *gem*, in the general, see below. The origin and formation of *precious stones*, see *STONE*. For the art of engraving on *precious stones*, see *ENGRAVING*. The art of cutting them, see *LITHOGRAPHY*. Mosaic work of *precious stones*, see *MOSAIC*.

Pearls are also ranked among *gem*, though not stones.

Gems are sometimes found of regular shapes with a natural polish, and others of round, after great rains, and these are of the pebble kind, and sometimes of irregular shapes, with a rough coat, in mines, and the debris of rocks. Those of the first sort are the *gem*, on which the ancients engraved, and which are commonly called intaglios; these are usually of a long oval figure inclining to a point at each end, convex as well upon the engraved surface as on the others, and having a ridge running from end to end on the under side, which is thereby as it were divided into two faces, both which are also, though not so distinctly, parted from the upper face by another ridge running quite round the oval. The stone most frequently engraved on, is what the jewellers call the beryl, a somewhat different stone that called the beryl by the ancients, which was the *gem* we call the aquamarine.

This beryl of the jewellers is only a finer kind of cornelian, and is of three kinds; the red, the yellow, and the white. The first is much the most valuable of these, and is of the greatest luster; that which is most frequent next this beryl, is the prasiolite, or, as some call it, the *plasma di forasione*. This our jewellers call the *prase* or *prase emerald*. It is of a somewhat dusky green, and is sometimes tolerably clear, but most usually it is full of black and white specks, and rather opaque.

The most frequent next to these is the jacinth or hyacinth. This also is not the *gem* known by the ancients under this name, that having been a sort of amethyst; but the stone we now call the hyacinth, which is of a tawny red, or a sort of rose-colour, and is very bright and transparent. The chrysolite is sometimes, but rarely, found engraved on. It is of a greenish colour, and is transparent, but not lively. Sometimes we also meet with the oriental pebble crystal, which is much more transparent and lively than the common crystal, and indeed but little inferior in beauty to the white sapphire; this *gem*, which is of a deep red, and not so lively as the hyacinth; and, finally the amethyst, which is of a deep purple, and is very lively and transparent. This seem to have been all the stones used in the earlier times of the Roman empire. There are indeed, sometimes found some other species, but their use is of any time but the later ages, as the empire, when the artificial was greatly upon the decline. The before mentioned stones are said to have been brought to Rome from the borders of the Nile, or of the Ganges. The onyx, agate, cornelian, and alabastrer of two colours, were also engraved on by the Romans in a different manner. There are also certain shells of different coats, were frequently engraved in relief, and these sorts of engravings are commonly called *caros*; they also sometimes engraved a head, or some other figure, in relief of gold upon a silver stone.

Beside these there are also some antiques, mostly cornelians, which are covered with a thistle of white. This thistle has by some been looked on as natural, but it was really only a sort of coat or enamel that was laid on: this was used only in the times of the lower empire. The ancients engraved many of their stones just as they were found with their native polish, and in their native shape; but the beauty of the several species of the onyx could only be shown by a proper cutting. The antique *gem* of Greek work are of all others the most esteemed, and next to them the Romans, in the time of the higher empire. Ptol. Traut. N. 183. or vol. xiv. p. 302. &c. Several authors, both ancient and modern, relate wonders of the virtues and medicinal properties of *gem*; but their reputations in this respect, is now a little fallen; and many even deny them any virtue at all. Yet are the fragments of such stones still preserved by some physicians in some of the most celebrated compositions; and there are several chemical preparations made of them. In reality, as several persons of the greatest candour and

experience have related some considerable effects of certain *gem*, on their own particular observations; and it is no way improbable, that some of the lesser stones may have considerable operations on the human body, it might be imprudent and unnecessarily to exclude them from any medicinal virtue at all.

Which would the greatest part of their medicinal qualities is for stone, as fardony, there will find regimen there, on as real and well-arranged a footing as many of our other medicines.

On such considerations, Mr. Boyle was induced to give as a recital of the Origin and Virtues of *Gems*; the purpose whereof is to show that such stones were originally in a solid state, or made up of such substances as were formerly fluid; and that many of their general virtues are probably derived from the mixture of metallic and other mineral substances usually incorporated with them; while the great variety, and the particular efficacy of their virtues, arise from some happy concurrent circumstances of that mixture; e. g. the peculiar nature of the impregnating liquor, the proportion wherein it is mixed with the petreous matter, and the like.

To support this hypothesis of the origin of *gem*, he shews, that several of them are not simple concretions of any petreous liquor; but that they consist, also, of other mineral ingredients; parts, which he argues, from the separableness of such substances in some stones, the specific gravity in others, and the different waters, or fluids to be met with in *gem* of the same species; as rubies, sapphires, granates, and even diamonds, of which last some are yellow, some of other colours, and some green, almost like emeralds.

There may, therefore, be in some *gem* numberless salutiferous compounds; but there is great reason to think that some of these compounds may be endowed with several properties, and medicinal virtues. There is a great difference among those impregnating particles; and, probably, a greater variety than known by us; and, lastly, many *gem* are very richly impregnated with their particles; why, then, may not they exert some power? This is the substance of what is directly stated in the behalf of *gem*.

The basis of what is objected against them, is, that the mineral substances they contain, are so closely locked up, that they can communicate nothing to the body, and to can have no medicinal operation, being uncommunicable by so small a heat as that of the stomach, and other parts of the body.

This objection might be plausible enough to prevent one admitting any medicinal virtues to them; *gem*; but can conclude nothing against what is warranted by so many facts and observations; especially when there are several particulars that obviate this objection.

For a vigorous digestion, though frequently hinder than many *gem*, is known to emit copious exhalations; and there are many which have been found to have a manifest and incommunicable operation on the human body, by being worn in the pocket, or long held in the hand. Mr. Boyle has found divers transparent particles, which, when cut would resemble diamonds, that might be immediately brought to emit copious and strong scented steams; and if electrical situations be given to the vitallity of bodies raised by rubbing, very light operations may follow to procure exhalations from transparent *gem*, many of which are electrical, and even the hardest of all, viz. diamonds; one of which Mr. Boyle kept by him, which, upon a little friction, would strain very vigorously.

To that part of the objections which proceeds, *gem* not to be digested by the heat of the stomach, it may be replied that we do not know how far the digestion of things in the stomach is owing to heat; nor is it proved, that such materials can have operation on the body, without being digested, i. e. in passing through it without undergoing any sensible change of bulk, figure, &c. as *gem*, when swallowed, are supposed to do.

For some chemists make a kind of bullets of regulus of antimony, which they call *galea perfracta*; because, when they have performed their operation on the body, and are cast forth with the excrements, they may be used again and again, for the same purpose; and so we know what analogy there may be between some juices in the body, and those mineral parts which impregnate *gem*. For though the *galea* must be reckoned among the *gem*; yet, if one of the best sort be, for a while, kept in common water, it will undergo an alteration obvious to the eye.

And, that Mr. Boyle has, without heat, obtained a manifest tincture from several hard bodies, and even from a transparent sort of *gem*, by means of a faint liquor distilled from a vegetable substance, as burniac, and as plentifully eaten, as bread; and whether some juices of the body, assailed by the natural heat thereof, may not serve

for menfures to some *gem*, we will not say: between the natural heat of a human ftonch, and, perhaps, of the external parts of the body, may be able, though not to digest precious ftones, yet to fufain fome of their virtues: for it is certain, it makes a fenfible alteration in the harded fort of them. What is a diamond of Mr. Boyle's, whole electrical faculty might be exalted, without rubbing, only by a fanguine degree of aduftion heat; and another, which, by means of water made a little more than lukewarm, might be brought to fling in the dark. See *PHOSPHORUS*, Boyle's Works abridged, vol. I. p. 62.

Lastly, if it be yet objected, that it is not likely *gem* should part with any effluvia, or portions of themselves, inasmuch as they lose none of their weight, it may be answered, that the autumnal glass and cup imbue wine, and other liquors, with a strong emetic quality, without undergoing any fenfible diminution of weight. Add, that though common water be not allowed a menftruum fit to draw any thing from mercury; yet both Helmont and others, inform us, that a large quantity of it, being kept a day, or two, upon a small proportion of that drug, will acquire a virtue of killing worms, though the mercury retains its former weight.

Gems, imitation of antique. There has been at different times a method practised by particular persons of taking the impreffions and figures of antique *gem*s, with their engravings, in glass of the colour of the original *gem*. This has always been esteemed a very valuable method, and greatly preferable to the more ordinary ones of doing it on sealing-wax or brimstone; but, to the misfortune of the world, this art being a secret only in the hands of some particular persons, who got their bread by it, died with them, and every new-artist was obliged to new invent the method, till at length Mr. Homberg, having found it in great perfection, gave the whole process to the world to be no more forgotten or lost, and since that time it has been very commonly practised in France, and sometimes in other places.

Mr. Homberg was favoured in his attempts with all the engraved *gem*s of the king's cabinet, and took such elegant impreffions, and made such exact resemblances of the originals, and that in glasses so artfully tinged to the colour of the *gem*s themselves, that the nicest judges were deceived in them, and often took them for the true antique ftones. These counterfeit *gem*s will serve as well as the original ones, to make more copies from afterwards; so that there is no end of the numbers that may be made from one; and there is this farther advantage, that the copy may be easily made perfect, though the original should not be so, but should have sustained some damage from a blow or otherwise. Mem. Acad. Par. 1717.

The great care in the operation is to take the impreffion of the *gem* in a very fine earth, and to press down upon this a piece of popes glass, softened or half melted at the fire, so that the figures of the impreffion made in the earth may be nicely and perfectly expreffed upon the glass. In general, the whole process much resembles that of the common founders. But when it is brought to the trial, there is found a number of difficulties which were not to be foreseen, and which would not at all affect the common works of the founder. For his purpose every earth will serve, that is fine enough to receive the impreffion, and tough enough not to crack in the drying; these all serve for their use, because their metals which they cast use of a nature incapable of mixing with earth, or receiving it into them, even if both are mixed together, so that the metal always easily and perfectly separates itself from the mould; but it is very difficult in these casts of glass. They are composed of a matter which differs in nothing from that of the mould, but that it has been run into this form by the force of fire and the other has not yet been so run; but is on any occasion ready to be so run, and will mix itself inseparably with the glass in a large fire, and, consequently, if there be not great care taken, as well in the choice of the glass as in the manner of using it, when the whole is finished, there will be found great difficulty in the separating the glass from the mould, and often this cannot be done without wholly destroying the impreffion.

All earths run more or less easily in the fire, as they are more or less mixed with saline particles in their natural formation. As all salts make earths run into glass, and as it is necessary to use an earth on this occasion for the making a mould, it being also necessary in the perfection of the experiment, that this earth should not melt or run, it is our business to search out for this purpose some earth, which naturally contains very little salt. Of all the species of earth which Mr. Homberg examined on this occasion, none proved so much devoted of salt, or to fit for the purpose, as the common tripels, or tripoli,

used to polish glass and ftones. Of this earth there are two common kinds, the one reddish, and composed of several flakes or strata, the other yellowish, and of a simple structure. These are both to be had in the floys. The latter kind is from the Levant, and the former is found in England, France, and many other places. This tripels must be shaken soft and smooth to the touch, and mixed with fandy or other extraneous matters. The yellowish kind is the best of the two, and is commonly called Venetian tripels. This receives the impreffions very beautifully, and mixes with the glass in the operation, which the red kind sometimes does. Mr. Homberg usually employed both kinds at once in the following manner; first, powder a quantity of the red tripels on an iron mortar, and fitting it through a fine sieve, let it by for use, then temper with a little quantity of the yellow tripels into a sort of powder, and afterwards rub it off very fine in a glass mortar with a glass pebble. The finer this powder is, the finer will be the impreffion, and the more accurately perfect the cast. The artist might naturally suppose, that the best method to obtain a perfect fine powder of this earth, would be by washing it in water, but he must be cautioned against this. There is naturally in this yellow tripels a sort of unctuousness, which when it is formed into a mould keeps its granules together, and gives the whole an uniform glossy surface; now the washing the powder takes away this unctuousness, and though it render it much finer, it makes it leave a granulated surface, not this smooth one in the mould, and this must render the surface of the cast less smooth.

When the two tripels are thus separately powdered, the red kind must be mixed with so much water as will bring it to the consistence of palle, so that it may be moulded like a lump of dough between the fingers; this palle must be put into a small crucible of a flat shape, and about half an inch or a little more in depth, and of such a breadth as the surface as is a little more than that of the fstone whose impreffion is to be taken. This crucible is to be nicely filled with this palle, lightly pressed down into it, and the surface of the palle must be smoothed over with the fine powder of the yellow tripels not wetted. When this is done, the fstone, whose impreffion is to be taken, must be laid upon the surface, and pressed evenly down into the palle with a finger and thumb, so as to make it give a strong and perfect impreffion; the tripels is then to be pressed nicely even to its sides with the fingers, or with an ivory knife: the fstone must be thus left a few moments, for the humidity of the palle to immit the dry powder of the yellow tripels which is spread over it; then the fstone is to be carefully raised by the point of a needle fixed in a handle of wood, and the crucible being then turned bottom upwards, it will fall out, and the impreffion will remain very beautifully on the tripels.

If the sides of the cavity have been injured in the falling out of the fstone, they may be repaired, and the crucible must then be set, for the palle to dry, in a place where it will not be incommoded by the dail.

The red tripels being the more common and the cheaper kind, is here made to fill the crucible only to save the other, which alone is the substance in for taking the impreffion. When the fstone is taken out, it must be examined, to see whether any thing be lodged in any part of the engraving, because if there be any of the tripels left there, then will certainly be so much wanting in the impreffion. When the crucible and palle are dry, a piece of palle must be chosen of a proper colour, and cut to a size proper for the figure; this must be laid over the mould, but in such a manner that it does not touch the figures, otherwise it would spoil them. The crucible is then to be brought near the surface by degrees, and gradually heated till it cannot be touched without burning the fingers; then it is to be placed in the furnace under a muffle, surrounded with charcoal. Several of these small crucibles may be placed under one muffle, and when they are properly disposed, the aperture of the muffle should have a large piece of burning charcoal put to it, and then the operator is to watch the process, and see when the glass begins to look bright; this is the first of its being fit to receive the impreffion. The crucible is then to be taken out of the fire, and the hot glass must be pressed down upon the mould with an iron instrument, to make it receive the regular impreffion; as soon as this is done, the crucible is to be set at the side of the furnace out of the way of the wind, that it may cool gradually without breaking. When it is cold, the glass is to be taken out, and its edges should be grated round with pincers, which will prevent its flying afterwards, which is an accident that sometimes happens: when this caution has been omitted, especially when the glass is naturally tender. The different coloured glasses are of different degrees

degrees of hardness, according to their composition, but the hardest to melt are always the best for this purpose, and this is known by a few trials.

It is best to copy a stone in relief, which is naturally in relief, or to take one to erect, which is naturally in relief, there are no more than to take an impression first in wax or sulphur, and to mould that upon the pale of a stone instead of the stone itself; then proceeding in the manner before directed, the process will be well directed. *Mem. Acad. Par. 1711.*

GEM, JACOB, *Yehia gemah*, a name given by Ptolemy, and some other of the ancients, to a gem of a reddish colour, which, according to their accounts, afforded a purple colour when rubbed; another kind of it is also mentioned, which was white and looked silky.

GEMARA, or GEMARA, the second part of the TALMUD.

The word גמרא, *gemara*, is commonly supposed to denote a supplement; but it signifies, it rather signifies completion, perfection; being formed of the Chaldee גמ, *gama*, or *gemah*, to finish, perfect, or complete any thing.

The rabbins call the *Pemerkah*, simply, the law. The first part of the Talmud, which is only an explication of that law, or an application thereof to particular cases, with the decisions of the ancient rabbins thereon, they call the *Mishnah*, i. e. second law; and the second part, which is a more extensive and ample explication of the same law, and a collection of decisions of the rabbins posterior to the *Mishnah*, they call *Gemara*, q. d. perfection, completion, finishing; because they esteem it the finishing of the law, or an explication, beyond which there is nothing farther to be desired.

The *Gemara* is usually called, simply, Talmud, the common name of the whole work. In this sense we say, there are two *Gemaras*, or Talmuds; that of Jerusalem, and that of Babylon: though, in strictness, the *Gemara* is only an explication of the *Mishnah*, given by the Jewish doctors in their schools; much as the commentaries of our school divines on St. Thomas, or the master of the sentences, are an explication of the writings of that author.

A commentary, Monsieur Tillamont observes, was wrote on the *Mishnah*, by one Jochanan, whom the Jews place about the end of the second century: but Fa. Marin proves, from the work itself, wherein mention is made of the Turks, that it was not wrote till the time of Herodotus, or about the year 620; and this is what is called the *Gemara*, or Talmud of Jerusalem, which the Jews do not use or esteem much, because of its obscurity.

They treat much greater value on the *Gemara*, or Talmud of Babylon, begun by one Aba, discontinued for seventy-three years, on occasion of the wars with the Saracens and Persians; and finished by one Jofa, about the close of the seventh century. See TALMUD.

Though the name Talmud, in its latitude, includes both the *Mishnah*, and the two *Gemaras*; yet it is properly that of Aba and Jofa, alone, which is meant under that name. This Jews prize above all their other writings, and even set it on a level with Scripture itself: in which they conceive it as the word of God, derived by tradition from Moses, and preserved, without interruption to their time. R. Jochanah, and afterwards R. Jochanan, R. Aha and R. Jofa, having the traditions should be lost in the dispersion of the Jews, collected them into the *Mishnah* and the *Gemara*. See CALATHEA and RABBINISTS.

GEMATRIA, or GAMETRIA, the first kind of artificial CABBALA used by the Jews.

The words formed from the rabbinical Hebrew גימטריא, formed by corruption of the Greek.

Gematria is a geometrical or arithmetical method of explaining words, whereof there are two kinds; the first bearing a more immediate relation to arithmetic, and the latter to geometry.

The first consists in taking the numerical value of each letter in a word or phrase, and giving it the sense of some other word, whose numerical letters, taken after the same manner, make the same sum. For it is to be observed, that neither the Hebrews, nor the Greeks, have any numerical figures besides the letters of the alphabet.

Thus, a cabbalist, taking the two first words in Genesis, בראשית ברא, and by addition getting the sum total of all the numbers, signified by those letters, finds that the two words signify the same as those other three words, הנהגות בראשית. For, as to the first, ב, is 2; ר, 200; נ, 5; ש, 300; י, 10; מ, 400; ז, 7; ו, 6; and N, 1, which, together, make 1116. And, as to the latter, ה, signifies 5; ר, 200; נ, 5; ש, 300; ו, 6; י, 10; מ, 400; ז, 7; ו, 6; ב, 2; ר, 200; ו, 6; which, summed up, yield the same number 1116.

Whence the cabbalist concludes, בראשית ברא, in the beginning he created, signifies the time when the world began to be created, at the beginning of the year 5, and, accordingly, the received opinion of the cabbalists is, that the world was created at the beginning of the month Tishri, which was anciently the first month in the year, and answers to our first month in autumn, viz. September.

So, again, in the prophesy of Jacob, Gematria: to the words בראשית ברא, a word of the Mishnah because they write the same number with גימטריא, which signifies the Mishnah. The second kind of *gematria* is much more obscure and difficult; and, accordingly, is less used. It is employed in seeking for subtle and hidden interpretations in the dimensions and parts of the buildings mentioned in scripture, by dividing, multiplying, &c. those measures by each other. Of this we shall give an example from some Christian cabbalists.

The scripture says, that Noah's ark was 300 cubits long, 50 wide, and 30 high: now the cabbalist takes the length for the basis of his operations, 300; in the Hebrew, is expressed by the letter ש, which length, divided by the height 30, gives the quotient 10, the Hebrew character whereof is י; this is to be placed on the right side of ש; he then divides the same length by the width 50, the quotient whereof, 6, is expressed by a ו, which, being placed on the left side of ש, makes, together with the other two letters, the name Jesus, ישו. Thus, by the rules of the cabbala, it appears, that there is no revelation but in Jesus Christ; as, at the deluge, no person was saved but those in the ark.

After the like manner is the same name ישו found in the dimensions of Solomon's temple. But is rather an injury than an advantage to the Christian religion, to support it by such frivolous evidences.

GEMELLES, in Herakly, a bearing of horns by pairs, or in couples, in a coat of arms. Hebereth gives on a chevron argent, three bars gemelles habes, by the name of Thromorton.

GEMELLUS, in Anatomy, a muscle of the arm, called also biceps externus, 2 having two heads. See Tab. Anat. (Myol.) fig. 1. n. 20. fig. 6. a. 14. fig. 7. n. 13. 13. 13.

One of the heads of this muscle rises tendinous from the upper part of the inferior costa of the scapula; whence passing between the muscles to the back part of the humerus, it joins the other head, and both run together to their insertion at the ancon or tip of the elbow. The *gemelli* is the first extensor of the cubit, and is by many reckoned two distinct muscles; the first called *separatus*, the latter *brevis*.

GEMINATED constell. See COLUMN.

GEMINI, in Astronomy, the TWINs; a CONSTITUTION, or SIGN of the zodiac, the third in order, representing Castor and Pollux; and it is marked thus, ♊.

The stars in the sign *Gemini*, in Ptolemy's catalogue, are 25; in Tycho's, 25; in Hevelius's, 38; in the Britannic Catalogue, 85. The order, names, longitudes, latitudes, magnitudes, &c. whereof, are as follow:

Names and Situations of the Stars.	Right Ascension.	Longitud.	Latitud.	Magnitude.

GEMINI, in *Anatomy*, two muscles of the thigh, which arise from the puberance of the ilium, and are inserted with the pyriformis into the dent at the root of the great trochanter.

These are called *gemini* by Winslow. The superior or smaller *gemelli* is fixed to the lower part of the spine of the os ilium, to the inferior part of the small ischiatic notch, and to a rough line which runs cross the outside of the ilium, beginning at the spine, and continuing under the acetabulum, where it is bent downward.

The inferior and larger *gemelli* is fixed to the isopexion and back part of the tuberosity of the ilium, and to a rough impression, which runs cross the outside of the ilium, from the lower extremity of the ischiatic notch and is bent upward toward the other line, together with which it forms about of regular semi-circle. Both these muscles have a small insertion in the inside of the ilium, where being united together by a particular

membrane, one of them joins the upper side, and the other the lower side of the *obturator internus*, a little after it has passed over the notch. They include it as in a bag, and continue to be fixed to it by fleshy fibres all the way to its extremity. The superior muscle terminates wholly with the tendon of the *obturator internus*, but the inferior, being broader, is inserted likewise by fleshy fibres in the orbicular ligament, and under the tendon of the same obturator. Winslow's *Anat.* p. 210.

GEMMA. See **GEM**.

GEMMA, *fab.* is peculiarly used for each *SALT*, or salt dug out of mines.

The name *gemma* is applied to this on occasion of its lustre and brilliancy, which is not unlike that of a crystal. The principal mines of this salt are those of Wilkes, in Poland; those of Linnus, in Upper Hungary; and those of Cardonne, in Catalonia.

The chief uses of this salt is for the powdering or pickling of meats, in places destitute of salt-petre, &c.

GEMMA, or **GAM**, among old *Physiologists*, the rugged bud of a vine, or other tree, when it is beginning to burst called *alga* *malva*, &c.

Gemmae sunt quae vitem vasa gerunt. Cic. *de Senectute* cap. 37.

GEMMAE, *geminae*, in *Natural History*, a name given by some of the Latin poets, and other authors in that language, to a *gem*, which was much esteemed by the Romans, and set in rings. It was called by the Greeks *Amethyst*. Many have supposed this to be the opal; but it is certain from the oldest accounts, that the most beautiful kind of the amethyst was the *gemma* they called by this name. They distinguished the amethyst, as all the other *gemae*, into several kinds, according to the degrees of the colour; and to the most eminent of these they gave peculiar names, as is evident in the several kinds of the emerald and beryl. The most amethystine were those which had very little colour beyond that of crystal, and the very best were those which had the mixed red of the carbuncle, mixed with the purple of the sardius, and the whole so pale, that a pale colour seemed blended with them, and predominating over the rest. These, Pliny tells us, were called *pederasti* and *amethysti*, and were the *gemae* culled from their beauty, *Apollonius lapidi* and *gemmae* *laureae*; but all these names have been since given by others to the opal.

GEMMEUM, an epithet used by the Latins to express such vessels as were called *amethysti* and *chalcidii* by the Greeks. The more correct Roman authors, however, call this *gemmatum* *praeconium*, and not *gemmae*; the word *gemmae* signifying properly a vase or cup, cut out of a single stone, as an agate, or the like; but *gemmatum* expressing those fine vessels of gold, which were ornamented with emeralds and other precious stones.

GEMONIA, *juvis*, or *gradus GEMONIA*, among the Romans, was much the same as a gallows, or gibbet, in England.

Some say, they were thus denominated from the persons who raised them; others, from the first criminals that suffered on them; and others, from the verb *gemo*, I *grob* or *groan*.

The *gradus geminae*, according to Papius Vitor, or Sextus Rufus, was a place raised on several steps, from whence they precipitated their criminals; others represent it as a place whereon offenders were executed, and afterwards exposed to public view. The *geminae* *foveae* were in the tenth region of the city, near the temple of Jano. Camillus first appropriated the place to this use, in the year of Rome 378.

GEMONIDES, a name by which some of the ancients have called the praetoria; probably the same with our *shambles*, a name famous with them for its supposed virtue in promoting delivery.

GEMOTE, or **GEMOT**, *conventus*, a Saxon word, denoting a meeting or assembly.

Gemiti sunt facies habentes canes ad gemotum et vultus de gemoto, nisi gemiti sunt facies. LL. Ed. Conf. See **WATKINS**.

GEMURA, a word used by the ancient writers in *Medicine*, for a distemper which was an excrescence of flesh between the teeth, a disease not known with us.

GEM. See **CHEEK**.

GEM. See **QUADRATUS**.

GENDARMES, or **GEND'ARMES**, *q. d.* men of arms, a term used among the French for a select body of horse-guards: because they succeeded the ancient *filles* of arms, who were armed at all points, and thence were called *gendarmes*.

At present, the troops of the king's guard de corps, the mousquetaires, and light-horse, are reputed to belong to the *gendarmes*.

The *grand-gendarmes*, sometimes called simply the *gendarmes*, are a troop of gentlemen, to the number of about

about 200, and in time of war 240, who guard the king's person. The king himself is his captain, and one of the prime peers the captain-leutenant, under whom are two sub-leutenants, three captains, and three guidons. When the king marches with all his household troops, the *gens d'armes* close the march. They were established about the year 1655.

Their device is a thunder-bolt falling from heaven, with the motto, *Deus vult sapere*. There are also, beside these, *gens d'armes* of the queen, the dauphin, &c.

The *carabinieri*, at present, is a body of horse, consisting of sixteen companies, forming eight squadrons, viz. the Scotch *carabinieri*, the English *carabinieri*, the Burgundian *carabinieri*, and the Flemish *carabinieri*, which four companies compose the king's *gens d'armes*, or life-guard. The other companies take their names from the princes who command them as captains, viz. the queen's *carabinieri*, the queen's light horse; the dauphin's *carabinieri*, the dauphin's light horse; the duke of Burgundy's *carabinieri*, the duke of Burgundy's light-horse; the duke of Orléans's *carabinieri*, &c. each troop, at a medium, consists of seventy-five *carabinieri*, or light horse. Each company is divided into two brigades, one commanded by the captain-leutenant, and the other by the sub-leutenant, and the subordinate officers are an ensign and guidon.

GENDER, GENUS, in Anthropology. See **GENUS**.

GENIUM, in Cosmology, denotes a division or distinction of nouns, or names, according to the different sexes of the things they denote.

It has been thought proper, in order to render discourse more exactly and distinctly, to also to embellish it by a variety of terminations, to denote certain diversities in subjects, accommodated to the substantives they are applied to; whence, from a regard to the notable difference there is between the two sexes, all nouns substantives have been distinguished into masculine and feminine; and the nouns adjectives also varied to correspond therewith.

Mr. Harris observes, that in the distribution of *genera*, such substantives might have been considered as masculine, which were conspicuous for the attributes of imparting and communicating; or which were, by nature, active, strong, and efficacious, and that indifferently whether in good or ill; or which had claim to eminence, either laudable or otherwise: the feminine, on the contrary, were such as were conspicuous for the attributes either of receiving, of containing, or of producing and bringing forth; or which had more of the passive in their nature than of the active; or which were peculiarly beautiful and amiable; or which had respect to such exercises as were rather feminine than masculine. Thus the sun, the sky, time, death, God, &c. are masculine; but the moon, the earth, a ship, a city, country, virtue, fortune, &c. are feminine. *Hermes, p. 44, &c.*

But as there was an infinity of words, which had no proper relation, either to the one sex, or the other, they had *genera* assigned them, rather out of caprice than reason; and hence it is that the *genera* of a noun is frequently dubious and fluctuating. Though, as there are substantives, that have evidently no sex, the neuter *genus* encompassing such substantives is so natural and rational a distinction as either of the others.

It should here, however, be observed, that this institution of *genera* was not made with design and deliberation by the creators of language, but was introduced by custom and usage. At first, there was only a difference between the names of animals, when spoke of males and females; and, by degrees the same regulation was extended to other things; the grammarians have only noted and allowed what usage had established. The oriental languages frequently neglect the use of *genera*; and the Persian language has absolutely none at all, which is no disadvantage; the distinction of *genera* being in great measure useless.

The Latins, Greeks, &c. generally content themselves to express the different *genera* by different terminations, as *homo sapiens*, a *good horse*, *homo sapiens*, a *good mare*, &c. but in English we frequently go farther, and express the difference of sex by different words; as *boy*, *girl*, *son*, *daughter*, *bull*, *cow*, *cock*, *hen*, &c. *Idem, p. 44, &c.*

We have only about twenty-four feminines, distinguished from the males, by the variation of the termination of the male into *us*, of which number are *abbot*, *abbot*, *count*, *convent*, *actor*, *actress*, *hero*, *heroine*, *prince*, *princess*, &c. which is all that our language knows of any thing like *genera*.

The eastern languages, as well as the vulgar languages of the West, have three *genera*; the masculine, feminine, and neuter. The Greek and Latin have likewise the

neuter, common, and the doubtful *gender*; and besides these, they have the epicene, or promiscuous, which under one single *gender*, and termination, includes both the kinds.

The English language, with singular propriety, following nature alone, applies the distinction of masculine and feminine only to the names of animals; all the rest are neuter, except when by a poetical or rhetorical fiction, things inanimate and qualities are exhibited as persons, and consequently become either male or female. And this gives the English an advantage above most other languages in the poetical and rhetorical style; for when nouns naturally neuter are converted into masculine or feminine, the personification is more distinctly and sensibly marked. Lowth's Grammar, p. 42. ed. 1772.

GENDER, in Geometry. GEOMETRICAL lines are divided into *gender*, or *gender*, *gender*, or *gender*, according to the number of the dimensions of the equation that expresses the relation between their ordinates, and the abscissæ.

GENDER, in Botany.

GENDER, in Astrology. See **GENUS**.

GENEALOGICAL ORDER. See **ARBORE**.

GENEALOGY, a series or succession of ancestors, or progenitors, or a summary account of the relations and kindred of a person, or family, both in the direct and collateral line.

The word is Greek, *γενεαλογία*, which is formed of *γενεα*, *genos*, *progenitor*, *race*, and *λογία*, *and*, *logos*, *form*, *discourse*.

In direct chapters, and military orders, it is required, that the candidates produce their *genealogy*, to show that they are noble by so many descents.

Genealogical tables, genealogical trees, genealogical track, or chains, &c. See **ARBORE**.

The *genealogical degrees* are usually represented in circles, tinged over, under, and above of each other. The ancients had the like, which they called *genealogia*, from a Greek word, signifying *race*, *genos*, or *line*.

GENECANTHE, in Botany, a name used by some authors for the black henry.

GENERAL, something that comprehends all, or extends to a whole genus, or kind.

All the sciences have some general principles, or axioms.

A *general count*; *general councils* are particularly called *oecumenical*.

GENERAL officer, overment, council, diet, festival, food, geography, gravity, office, nature. See the several substantives.

GENERAL officers, in an army, are those who do not only command over a single company, or regiment, but whose office and authority extend over a body of several regiments of horse and foot.

Such are *BRIGADIER-GENERAL*, *LIEUTENANT-GENERAL*, *MAJOR-GENERAL*, *GENERAL* of the horse, of the foot. See **GENERAL**, below. See also **MAJOR-GENERAL**, **COMMISSARY-GENERAL**, **MASTER-MARTIN-GENERAL**, &c. and **PARTY**. We have also officers in law, in the revenue, &c. distinguished by the appellation of *general*; as, *ATTORNEY-GENERAL*, *SOLICITOR-GENERAL*, *SEC. RECORDER-GENERAL*, *COMPTROLLER-GENERAL*, &c.

GENERAL proofs, qualities, &c. See the substantives.

GENERAL terms, or words, are such as express or denote general ideas.

Ideas become *general*, by separating from them the circumstances of time, place, or any other ideas that may determine them to this or that particular existence.

By this way of abstraction they become capable of representing more individuals than one; each of which having a conformity to that abstract idea, is of that sort.

All things, Mr. Locke observes, that exist, being particular, it might be expected that words should be so too in their signification; but we find it quite contrary; for most of the words that make all languages, are *general terms*.

This is the effect of reason and necessity: for 1. it is impossible that every particular thing should have a distinct peculiar name; because it is impossible to have distinct ideas of every particular thing, to retain it in use with its peculiar appropriation to that idea. 2. It would be useless, unless all could be supposed to have the same ideas in their minds; for names applied to particular things, whereof one alone has the ideas in his mind, could not be significant, or intelligible to another, who is not acquainted with all those particular things which had fallen under his notice. 3. It would be of no great use for the improvement of knowledge, which, though founded in particular things, enlarges itself by *general views*, to which things reduced into sorts under *general names*, are properly subaltern.

In things, where we have occasion to consider and discourse of individuals and particulars, we use proper names.

names; as in persons, countries, cities, rivers, mountains, &c.

The first ideas children get are only particular, as those of the nurse, or mother; and the names they give them are confined to these individuals; afterwards observing that there are a great many other things in the world that resemble them in shape, and other qualities, they frame an idea, which they first make many particulars do partake in; so that they give, with others, the name, *nurse*, for example. In this they make nothing new, but only leave out of the complex idea they had of Peter, James, Mary, &c. that which is peculiar in each, and retain only what is common to all. And thus they come to have a *general* name, and a *general* idea.

By the same method they advance to more *general* names and notions; for, observing several things that differ from their idea of man, and which cannot, therefore, be comprehended under that name, to agree with man in some certain qualities, by retaining only those qualities, and uniting them into one idea, they have another more *general* idea; to which, giving a name, they make a *term* of a more comprehensive extension.

Thus, by leaving out the shape, and some other properties signified by the name, *man*, and retaining only body, with life, sense, and spontaneous motion, we form the idea signified by the name *animal*. After the same manner, the mind proceeds to body, substance, and at last to being, thing, and such universal terms, which stand for any ideas whatsoever.

Hence we see the whole mystery of genus and species is nothing but abstract ideas, more or less comprehensive, with names annexed to them: this flows as the reason why, in defining words, we make use of the genus; namely, to save the labour of enumerating the several specific ideas, which the next general term stands for.

From what has been said, it is plain, that *general* and *universal* being not to the real existence of things, but are the invention of the understanding, made by it for its own use, and concern only signs, either words, or ideas. *General* words do not touch equally one particular thing; for then they would not be *general* terms, but proper names: neither do they signify a plurality; for then man and men would signify the same thing; but what they signify is a sort of things, and this they do, by being made signs of abstract ideas in the mind; to which ideas as things existing are found to agree, so they come to be ranked under that name, or to be of that sort.

The essences then of the sorts, or species of things, are nothing but these abstract ideas.

It is not denied here, that nature makes things alike, and so lays the foundation of this sorting and classing; but the sorts or species themselves are the workmanship of human understanding; so that every distinct abstract idea is a distinct essence; and the names that stand for such distinct ideas, are the names of things essentially different. Thus oval, circle, rain, and snow, are essentially different. See the farther illustrated under *ABSTRACTION*, *ESSENCE*, *IDEA*, and *SUBSTANCE*.

General *troops*, *warrior*, *troop*. See the substantives.

General of an army is the chief commanding officer, whose business is to regulate the march and encampment of the army; to choose the most advantageous ground in the day of battle, to dispose the army, to post the artillery, and to send his orders wherever there is occasion, by his *adjuutants*. At a siege he is to cause the place to be invested, to regulate the approaches and attacks, to visit the works, and to find out detachments for securing the country and for foraging. See *GENERALISSIMO*.

The natural qualities of a *general* should be a martial genius, a solid judgment, a healthy robust constitution, integrity and self-possession on critical occasions, goodness of heart, liberality, and birth: he should also be of a mean age, neither too young, because he would want prudence and experience, nor too old, because he would want vivacity and activity. He should be steady and uniform in his conduct, amiable in his disposition, and yet inflexible in maintaining the discipline of his army. His acquired qualities should be secrecy, justice, sobriety, temperance, knowledge of the art of war both from theory and practice, the art of commanding and of speaking with precision; great attention in preserving the lives and supplying the wants of the soldiers, and a constant study of the character of the officers of his army, so that he may be capable of employing them according to their respective talents. His conduct appears in establishing his magazines in the most convenient places; in examining the country, that he may not engage his troops too far, while he is ignorant of the means of bringing them off; in procuring subsistence for them; and in selecting the most advantageous posts for fighting, retreating, or burning a battle. His experience informs his army with confidence; his quality, by creating respect, augments his

authority; his liberality enables him to procure intelligence of the strength and designs of the enemy, and thus to take the most successful measures. In a word a *general* ought to be fond of glory, to have an aversion to flattery, to render himself beloved, and to keep a strict discipline and subordination.

General of the artillery. See *ORDNANCE*.

General of *ships* is an officer next under the chief *commander*, who has an absolute command of the boats of an army, above the *marine-general*.

General of *foot* is to officer under the chief *general*, who has an absolute command of the foot of the army.

General, *adjutant*, is an officer who attends the *general*, assists in council, and carries the *general's* orders to the army. He distributes the daily orders to the majors of brigade. He is likewise charged with the general detail of the duty of the army. The *major* of brigade find every morning to the *adjutant-general* so exact return, by battalion and company, of the men of their brigade. In a day of battle the *adjutant-general* sees the infantry drawn up, after which he places himself by the *general*, to receive any orders which may regard the corps of which he has the detail. In a siege, he orders the number of workmen required, and signs the warrants for their payment. He receives the guards of the trenches at their rendezvous, and examines their condition; he gives and signs all orders for *parade*; he has an orderly servant from each brigade of infantry in the line, to carry such orders as he may have occasion to send from the *general*.

General is also used, in a small sense, for the chief of an order; or of all the houses or congregations established under the same rule.

Thus we say, the *general* of the Cistercians, the Franciscans, &c.

P. Thomassin traces the origin of *general* of orders from the privileges granted by the ancient patriarchs to the monasteries founded in their capital cities. By such means they were exempted from the jurisdiction of the bishops, and immediately subjected to that of the patriarch alone.

General of the *Hyacinth*. See *HYACINTH*, and *ADJUTANT*.

General is also used, in the *Military Art*, for a particular march, or beat of drum: being the first which gives notice, commonly in the morning call, for the infantry to be in readiness to march.

GENERALISSIMO, called also *Captain-General*, and simply *GENERAL*, is an officer, who commands all the military powers of a nation; who gives orders to all the other general officers; and receives no orders himself but from the king.

Mont. Balzac observes, that the cardinal de Richelieu first coined this word, of his own absolute authority, upon his going to command the French army in Italy.

GENERATED, or *GENERATE*, is used, by some mathematical writers, for whatever is produced, either in arithmetic, by the multiplication, division, or extraction of roots; or in geometry, by the invention of the contents, areas, and solids; or of extreme and mean proportionals, without arithmetical addition and subtraction.

GENERATING *line*, or *figure*, in Geometry, is that which by its motion or revolution, produces any other figure, plane, or solid. See *GENESIS*.

GENERATION, in *Physics*, denotes the act of generating, or producing a thing which before was not; as the total change or conversion of a body into a new one, which retains no sensible part or mark, of its former state.

Thus, fire is said to be generated, when we perceive it to be what before was only wood, or other fuel; or when the wood is so changed, as to retain no sensible character of wood; thus, also, a chick is said to be generated, when we perceive the chick, where before was only an egg; or when the egg is changed into the form of a chick.

In *generation*, there is not properly any production of new parts, but only a new modification or manner of existence of the old ones; by this, *generation* is distinguished from *creation*.

It is distinguished from *alteration*, in that the latter, in this sense, remains apparently the same; and only the accidents, or affections, are changed; as when the same body is to dry well, and to-morrow sick; or that which, while it was round, is now square.

Lastly, *generation* stands opposed to *corruption*, which is the utter extinction of a former thing; as, when that which before was wood, or an egg, is no longer the one or the other; whence it appears that the *generation* of one thing is the corruption of another.

The *Physicists* explain *generation* by a change or passage from a privation, or want of a substantial form, to the having of such a form. The moderns allow of no other change in *generation*, than what is local: according to them, it is only a transposition, or new arrangement of

parts; and thus the same matter shall successively undergo an infinity of generations.

A grain of wheat, &c. is committed to the ground: this, imbibing the humidity of the soil, becomes torpid, and dilates to such a degree, that it becomes a plant; and, by a continual accession of matter, ripens by degrees into an ear; and at length into new seed. This seed grown in the mill, appears in form of flour; which mixed with water, makes a paste; whereof, with the assistance of yeast, fire, &c. bread is generated; and this bread, broken with the teeth, digested in the stomach, and conveyed through the canals of the body, becomes flesh.

Now, in all this series of generations, the only thing effected is a local motion of the parts of the matter, and their setting again in a different order to that, in reality, wherever there is a new arrangement or composition of elements, there is a new generation; and therefore generation is finally reducible to motion.

Generation is more immediately understood of the production of animal and vegetable bodies from seed, or the coition of others of different sexes, but of the same genus, or kind.

Some modern naturalists maintain, after M. Perrault, that there is not properly any new generation; that God created all things at first; and that what we call generations, are only augmentations and expansions of the minute parts of the bodies of seeds; so that the whole species, to be afterwards produced, were really all formed in the first, and included therein to be brought forth and diffused to view in a certain time, and according to a certain order and economy.

The manner wherein directed of the male animal acts on that of the female, in order to impregnate, and render it prolific, has long been enquired after, and remains still a mystery.

The ancients distinguished two kinds of generation: *ex-gene*, called *maternal*; and *animalis*, called also *epigenesis*, or *post-natal*.

The first is that effected by parent animals of the same kind, as that of man, birds, beasts, &c. The second was supposed to be effected by corruption, the sun, &c. as that of insects, frogs, &c. But this latter kind is now generally and deservedly exploded. See *Equivocate*.

There are two principal theories, or methods of accounting for the generation of animals: the one supposes the embryo, or fetus, to be originally in the seed of the male; the other, in the ovum, or egg of the female.

The first supposes the animalcules found in the male feed, to be the first rudiments of the fetus; and that the female only furnishes a proper nidus, and nutriment, to bring them forwards.

The second supposes the first rudiments of the animal to be in the ovum; and that the male feed only serves to warm, cherish, and ripen the ova, till they fall out of the ovary into the uterus.

Dr. Harvey was of opinion, that all females are furnished with eggs; and that generation is effected wholly by means of the womb; which conceives the fetus by a kind of conglomeration communicated to it by the seminal fluid of the male, much in the same manner as the seed of the corn communicates vegetation to the soil. This conception, he supposed, acts not only on the uterus, but is communicated to the whole body of the female, which is altogether prolific; though the uterus, he acknowledges, is the only part that is capable of conceiving the fetus, just as the brain is alone capable of forming ideas and reasons. This ingenious physician and naturalist maintains, that the prolific fluid of the male neither does nor can enter into the womb of the female; but Verheyen has since actually found a great quantity of the male feed in the matrix of a cow, dissected sixteen hours after copulation; and the celebrated Ruysch, having dissected a woman who was surprised in adultery and assassinated on the spot, found a great quantity of the seminal liquor of the male, not only in the cavity of the womb, but also in the male artery. Other mistakes into which Dr. Harvey has fallen through the imperfection of the microscope in his time, notwithstanding his accuracy and diligence in observing, have been since detected by Malpighi, Leeuwenhoek, and others. The first of these is well illustrated by Dr. Geo. Garden. That author, upon comparing the observations and discoveries of Harvey, Malpighi, De Graaf, and Leeuwenhoek, together, concludes it most probable, "That all animals are ex-animalculo; that these animalcules are originally in female nutriment, and not in that of the female; but that they can never come forward, nor be formed into animals, without the ova in the female."

The rest of these points he argues from the three following observations.

1. That something has often been observed by Malpighi,

in the cicatrula of an egg before the incubation, like the rudiments of an animal, in form of a tadpole.

2. From the sudden appearance and displaying of all the parts, after incubation, it seems probable, that they are not then actually formed out of a fluid; but that the rudiments of them have been formerly there existent, and are now expanded. The first part of the chick, which is discovered with the naked eye, is the punctum album, and after not till three days and nights of incubation are past, on the fifth day the rudiments of the head and body appear. This made Dr. Harvey conclude, that the blood had a being before any other part of the body, and that from it all the organs of the fetus were both formed and nourished; but by Malpighi's observations it appears, that the parts are then only so far extended, as to be made visible to the naked eye; and that they were actually existent before, and discernible by glasses. After a further incubation of thirty hours, we see the head, the eyes, and the crura, with the vessels, distinct, and also the heart. After forty hours, its pulse is visible, and all the other parts more distinct, which cannot be discerned by the naked eye before the beginning of the fifth day; from whence it seems very probable, that even the so early discovery of those parts of the fetus by the microscope, is not the discerning of parts newly formed, but only parts more dilated and extended by receiving of nutriment from the colliquamentum; so that they seem all to have been actually existent before the incubation of the hen. And what Swammerdam has discovered in the transmutation of insects, gives no small light to this; since he makes it appear, that in those large cruce which feed upon cabbage, if they be taken about the time they retire to be transformed into aurelia, and plunged often in warm water, to make a rupture of the outer skin; you will discern, through the transparency of their second membrane, all the parts of the butterfly, the trunk, wing, feelers, &c. folded up; but that, after the cruce is changed into an aurelia, some of those parts can be discerned; but so much drenched with moisture, though they be there actually formed.

3. From the analogy between plants and animals. All vegetables, we see, do proceed ex plantula; the seeds of vegetables being no other but little plants of the same kind, folded up in coats and membranes; whence we may infer, that so curiously an organized creature as an animal, is not the sudden product of a fluid, or colliquamentum, but does much rather proceed from an animalcule of the same kind, and has all its little members folded up according to their several joints and pictures, which are afterwards enlarged and diffused, as we see in plants.

The second point, which our late discoveries have made probable, is, that these animalcules are originally in the seed of the male and not in the female. For,

1. There are observed innumerable animalcules in female mucus, of all animals. Hartsoeker and Leeuwenhoek have made this so evident, that there seems little room to doubt of it. See *ANIMALCULES*.

2. We observe the rudiments of a fetus in eggs which have been fecundated by the male; though no such thing is visible in those not yet fecundated. Malpighi, in his observations, makes it very probable, that these rudiments proceed originally from the male, and not from the female.

3. The resemblance between the rudiments of the fetus in ova, both before and after incubation, with the animalcules, makes it very probable that they are one and the same. The same shape and figure, which Mr. Leeuwenhoek gives as of the animalcule, Malpighi gives of the rudiments of the fetus, both before and after incubation; yes, and even the forties of viriparous animals appear so at first to the naked eye, whence Dr. Harvey acknowledges, that all animals, even the most perfect, are formed of a worm.

4. This gives a rational account of many forties at one birth; and how, at least, a whole cluster of eggs in a hen are fecundated by one coition of the male.

5. This gives a new light, as it were, to the first prophecy concerning the Messiah, that, "the feet of the woman shall bruise the head of the serpent;" all the rest of mankind being thus most properly and truly the feet of the man.

6. The analogy already mentioned, which we may rationally suppose between the manner of the propagation of plants and animals, does likewise make that probable. Every herb and tree bears its seed after its proper kind; which seed is nothing else but a little plant of that kind; which being thrown into the earth, as into its uterus, spreads forth its roots, and receives thence its nutriment, but has its form within itself; and we may rationally conjecture somewhat analogously in the propagation of animals.

The third thing which our discoverers make probable is that animals cannot be formed of these minute cells without the *ova* in females, which are necessary for supplying them with proper nutriment; and this is evinced from the following considerations.

1. It appears that an animalcula cannot come forward, if it does not fall into a proper situation; as we see in the cicatricle in eggs; and though a million of them should fall into one egg, none of them would come forward, but what were in the course of the cicatricle; and perhaps the others, according to their formation, it is proportioned to their bulk, that the body contain more than one animalcula; which must be the reason why there are so few monsters. This, we see, is absolutely necessary in the organic kind; and the only difference that lies between them and the vegetable, tends to be this, that in the latter the *ova* are properly nothing but the cicatricle, with its cultivation; so that the same must pass forth as soon as the uterus, to which it is united; but in the egg in viviparous animals may be properly termed an uterus, in relation to the fetus; as it contains not only the cicatricle, with its nutriment and cultivation, which is the true and immediate nutriment of the fetus; but also the materials which are to be converted into that cultivation; so that the fetus should forth in years no further than in the white and yolk of the egg, from whence it derives all its nourishment. Now, that an animalcula cannot come forward without some little proper nutriment, will not be denied; for if there were nothing present but their being thrown into the uterus, we do not see why many hundreds of them should not come forward at once, at least while fattened on so large a field.

2. That this cicatricle is not originally in *utero*, seems evident from the frequent conception which have been found extra *utero*; that as the child which continued twenty-five years in the woman of Theolonia's belly; and the little fetus found in the abdomen of Mad. de St. Mair, together with the scissile worm and fall of clotted blood, which also form to be the fetus in the abdomen of the woman of Copenhagen, mentioned in the *Nouv. de la Rep. des Lett.* for Sept. 1683; all the members of which were easily to be felt through the skin of the belly; and which the last carried in her belly for four years; the seven years gravitation related by Dr. Coler; and many other like instances. Now, granting once the necessity of a proper nutriment for the formation of an animalcula into an animal, these observations make it probable, that the testes are the *ova* appropriated for this use; for though the animalcules coming forth in such cases, may seem to be extraordinary; and that actually the impregnation is in *utero*; yet it may be collected from hence, that the cicatricle, or *ova* in be impregnated as in the scissile testicles; for if they were not by the accidental coming of animalcules (whether could we make them come forward more than in any other part of the body) since they cannot be formed and nourished without a nutriment.

3. It is acknowledged, that the fetus in *utero*, for some considerable time after conception, has no connection with the womb; that it fits wholly loose in it, and is no other than a little round egg, with the fetus in the middle; which feeds forth its nutriment solely by degrees, and at last lay hold of the uterus. Now from hence it seems evident, that the cicatricle, which is the fountain of the animalcula's nutriment, does not flow from the uterus, but has its origin elsewhere; and falls in thicker as into a fit fall, from whence it may draw nutriment for the growth of the fetus; else it cannot be easily imagined how it should not have an immediate connection with the uterus, from the time of conception.

It is indeed difficult to conceive, how these eggs should be impregnated by *seminal* matter, both because there is no connection between the Fallopian tubes, and the ovary for transmission; and because Dr. Harvey could never discover any thing of it in *utero*; but as to the fall, Mr. Leeuwenhoek has cleared that difficulty by the discovery of inseminable animals in the tube, or corpus *uteri*, and those things a considerable time after coition. And as to the fertility, we may either suppose, that there is such an infusion of the tubes, at the time of coition, as makes them embrace the ovary; or that in some sort of the uterus and *ovaria*, as that some early transmit the seed into the ovary; or else, that the *ova* are impregnated by the animalcules when they descend into the uterus, and not in the ovary. The former seems probable for this reason, that at least a whole cluster of eggs in a hen will be fertilized by one seed of the rooster; now this fecundation seems to be in the shell, and not in the uterus, as the eggs pass down from day to day; for it can hardly be supposed, that the animal-

cules should subsist so long, being feathered loosely in the uterus, as to wait there for many days, for the fecundation of the eggs as they pass along. The latter conjecture has this to strengthen it, that the animalcula is found in live a considerable time in the uterus; and that, if they should impregnate the *ova* in the uterus itself, the fetus would be crass in fall, that the *ova* could not pass through the tubes so fast, but would either burst the uterus, or fall down into the abdomen, from the order of the tubes; and from hence probably proceed those extraordinary conceptions in the abdomen, out of the uterus. Thus much is urged for the system as a *conjecture*. See *FOETUS*.

The relations in the system of generation of *ova* external, that the rudiments of the fetus are laid in the ovary; and that the female furnishes the whole matter of the body; which they chiefly depend from the continuation in embryo, fetus, growth, &c. where the system of the womb is large, and success, that it is scarce possible for the male seed should ever arrive within the body of the female, especially in cases, where the vagina is filled with coagula, which, though, and the inner orifice of the womb is exactly closed; besides that the thickness of the membrane of the *ova* should render impracticable to cross a matter as the male seed. Add, that if animalcules be found in the male fluids, which, however, will admit of some dispute (that insinuation motion and agitation of the sperm particles through, which give rise to the opinion, being accountable for, from the common laws of sperm fluidity; yet are the same observed in vinegar, pepper, water, &c. Add, that it is highly improbable, that these animalcules should contain the rudiments of a future body; since their large numbers would produce too plentiful an offspring; inasmuch that it would be needless for many parts of them to be in vain, and perish; which is contrary to the economy of nature in other things.

Analogy is likewise urged in favour of this system; thus all plants are maintained to arise from eggs; seeds being no other than eggs under another denomination. All oviparous animals do unexceptionably arise from eggs, which the females cast forth; and it is highly probable, that the viviparous only differ from the oviparous, in that the females lay and hatch their eggs within themselves.

Against this hypothesis it is urged, that what are usually called *ova*, or eggs, in women, are no other than follicles, or bladders, full of a certain liquor; and how can a drop of liquor pass for an egg? Add, that these imaginary eggs have no proper membrane belonging to them, nor any covering but that of the cell, which seems to be inseparable therefrom, that, when they are discharged, it is hard to conceive how they should take it with them. And hence, how should they make themselves a passage through the common membrane where the ovary is inserted, which is of so delicate a texture that it must form a difficulty impervious by a round body, or to let a coagulum as one of these vesicles? Lastly, observe, in all respects perfectly like *ova*, have been found in other parts of the body, when it is apparent they could not serve for any purpose of generation. *Mém. de l'Acad. Royal de Scien. ann. 1768, 1769.*

To do it is inferior, that *ova* or vesicles have been actually found in dissections, detached and separated from the ovary, and the ruptures in the membrane of the ovary, through which they had passed, remaining still visible. Mr. Lattre even observed some of these separated *ova* spread with blood vessels, like those in the yolk of a hen's egg. Nay, more, the same author is positive, that he saw an embryo in one of the *ova* not yet fertilized, and could discern in head, mouth, eyes, trunk and limbs; umbilical, whereby it adhered to the membrane of the ovary. See *GENERATION* of man.

Sir John Floyer has a difficulty, which seems to press equally against each system, taken singly; it is fetidities in men. In a male in infancy, which is the production of a venereal copula between an adult and a mare, the bulk of the body putrefies of the form of the dog, and the feet, tail, and ears, of that of the feline. Hence it is argued, that the rudiments of the greater part of the fetus are laid in the ovum; and that the impregnation either conveys or changes the extremities. If the male supplied the animalcula, the fetus should always be of the same species as the male; if the female herself it should be of her kind; whereas monsters are of both.

Three other systems of generation, which indeed to each resemble one another, that they may be reduced to one, have been lately formed from the experiments and observations of M. de Buffon, M. de Mairac, and M. de Neufville.

M. de Buffon has endeavoured to prove that the *ova* in reptiles and quadrupeds are chimeras, and that the

fermate animalcule cannot be the focus. He could never find any ova which had detached themselves from the ovary, and passed through the Fallopian tube into the matrix. But he discovered a glandular body on the female testicle, which anatomists had mistaken for one of these, which glandular body, at certain times, swelled, opened, and discharged a liquor full of the same animalcules, which Leeuwenhoek took for living creatures in the semen of males. And Mous. de Buffon adds, that he found bodies perfectly similar to these, not only in the semina of very different animals, but in the infusions of plants, of grains, and in the juices of fish-meats, dressed and prepared by the fire so as to leave no creature living in them. From whence this ingenious gentleman concludes, that these pretended animalcules are not future animals of the species of the father: he does not even allow them to be true animals, but says they are something of an intermediate nature between brute matter and animals; parts organized and animated, the assemblage of which forms the focus. See *Lettres de Mous. de Maupertuis*, lct. 17.

But the chief difficulty consists in conceiving how the focus is formed from these elements. Mous. de Buffon thinks that every part, both of animals and vegetables, contains an infinite number of organic molecules; but that they are much more numerous in the seminal liquors of both sexes, and in the seeds of plants, than in other parts. These organic parts serve for the nutrition and growth of animals and plants; and the surplus of these parts, when the other purposes to which they are adapted are answered, being retained in proper interior moulds, corresponding to the size and shape of the animal or vegetable to be produced, forms such animals or vegetables. Annulating the unity and diversity of the several species are preserved and continued. When the quantity of this organic matter is small, as in man and most large animals, *generation* only takes place at a certain age, of maturity, and even then the number of animals is but small. In other animals, as in fishes and most birds, abounding with these organic parts, the case is just the reverse. With regard to the *generation* of mankind, he supposes, that the superfluous organic parts are collected together into the seminal vessels of the male and the testicles of the female, which are the reservoirs destined to receive them; and in these reservoirs, they form a prolific liquor in each sex, which has been previously extracted from every part of the body. These seminal liquors, composed of parts alike active and perfectly analogous to one another, in form and motion, are mixed in the womb, and contribute, by uniting with each other, to the formation of the fetus, which is either male or female, as the seed of the man or woman abounds more with organic molecules; and the infant resembles either the father or mother, according to the different combinations of these molecules. The organic parts of these liquors, being equally active, fix and counterbalance each other, so that the molecules of each parent are determined to form similar parts to those of the individual that furnished them, as the head, arms, &c. The molecules proceeding from the genital parts fix themselves first; and the other molecules arrange themselves successively round these in the same order which they before occupied in the parent. When a great quantity of the seminal liquors of both sexes is collected into the womb, there are formed different spheres of attraction, in different parts of these liquors; the consequence of which is that several *foci* are formed at the same time. For a fuller account of Mous. de Buffon's system, we must refer to his *Histoire Naturelle*, printed at Paris, 1752, where the subject of the *generation* of animals takes up the greatest part of the third volume.

Mous. de Maupertuis's system, in his *Venus Physique*, has a near resemblance to that of Mous. de Buffon, and tends equally to overturn the systems of the ova, and of the spermatic animalcules, which have prevailed among modern physiologists. He ascribes the formation of the fetus to the mixture of the male and female seed, by mutual affinity and mutual attraction of the corresponding parts that compose them. And to confirm his own and Mous. de Buffon's opinion, he adds an account of a fecundatory family, as he calls it, at Berlin, many of which had a supernumerary finger or toe, and sometimes both. He says that this fecundity, or quality of having supernumerary fingers or toes, has been transmitted equally by the father and by the mother; that it was lost by alliances with those who had but the common number of fingers. He adds, that he does not believe that any one will ascribe the continuation of fecundity in a family, to chance; these supernumerary parts might have been accidental varieties at first, but if they be once established by a sufficient number of *generations*, where both sexes have had them, they then be-

come a foundation for a distinct species; and perhaps all the different species, discernible in animals of the same kind, have been multiplied in this way. What we may observe in other animals gives ground for these suspensions. See the letter before cited.

Mrs. Turberville Needham, in his Summary of Observations on the *Generation*, Composition, and Decomposition of Animal and Vegetable Substances, having offered several objections against the systems of *generation* by eggs and by animalcules, recites a multitude of experiments, from which he concludes, that there are no pre-existent germs formed for the production of animals and vegetables; but that matter, in some degree organized in its minute assemblages, gives birth to them, and that the gradation between animal and vegetable life is much more familiar and easy than it had before appeared to be. He supposes, in conformity to the doctrine of Mous. de Buffon, that there are in nature certain organic parts, disposed for the formation of animal and vegetable substances: that these by coalition, constitute the *prima flamina* of all animal and vegetable bodies, which are simple, uniform, and common to all, and consequently to be found in a certain quantity in every portion of food, aliment, or nutritive juice; and from thence to be digested, and when the subject becomes adult, to be secreted and trained, for the formation of the seed of every plant and animal; and in this fluid or substance to be afterwards found in great abundances. Their organic parts are declared to be moving when disengaged, living in appearance, and ended with certain organs, but extremely simple in their composition; being perhaps little more than elastic springs more or less compressed, and more or less diversified in the direction of their force. Into these organic principles Mr. Needham resolves that class of beings which has been denominated microscopic animals. He tells us, that seeds macerated in water first disintegrate into small particles, motionless and seemingly inert; but that these particles by degrees afterwards arrive at a power of motion, and seem alive, though in reality they are not so. The author deduces the same observations from experiments on the juices of animals, mutton gravy, and the like; and affirms, from the whole, that no axiom was ever more true than that of the ancients, *corruptio melius est generatio alterius*, though they draw it from false principles, and established it as to render *generation* equivocal. He then proceeds to the examination of the male semen of animals; and affirms, that these animalcules appearing like tadpoles, which others have observed in this semen, are produced subsequently to the excruciation of this fluid, and have their origin from principles contained in this matter, either by evolution of organic parts, as Buffon supposes, or, as Mr. Needham thinks, from a real vegetation, and a change from the vegetable to the animal life. He says, that this semen, immediately evacuated, and viewed by the microscope, appears an homogeneous fluid; that, after a few moments, it begins to liquefy; then to shoot out into long filaments and ramifications on every side; which afterwards open and divide into moving globules, trailing after them something like long tails; these tails are in reality no parts of the animals, but long strings or filaments of the viscid seminal substance, which gradually become shorter and shorter, till at last the globules get rid of them, and swim equally in the fluid. This vegetative power, in parts of the semen, of shooting into filaments, Mr. Needham found to reside in all substances animal and vegetable, and in every part of those substances; as far as the smallest microscopical point; and to this he attributes all that is called animal life in the fluids, produced from vegetables, or the infusions of them; and from hence he concludes with M. Buffon, that there is a real productive force in nature. He adds, that there is a vegetative force in every microscopical point of matter, and in every visible filament of which the whole animal or vegetable texture consists; and he also conjectures, that this force extends much farther; because in all his observations, the whole substance, after a certain separation of salts and volatile parts, divided into filaments and vegetated into numberless zoophytes, which yielded all the several species of common microscopic animals; and these animals also, after a certain time, subsided to the bottom, became motionless, resolved again into a gelatinous filamentous substance, and gave zoophytes and animals of a lesser species. The case is the same, he says, with regard to the spermatic animalcules, as well as the others, and, therefore, he reduces them all to the same class of beings. From these facts he infers, that every animal or vegetable substance advances as fast as it can in its resolution to return to one common principle, the source of all, or a kind of universal semen, from which its atoms may return again and ascend to a new life. He observes farther, that the

several species are kept distinct, because the specific food of one animal must undergo many changes, and acquire singular properties peculiar to itself, since it proceeded from the homogeneous element, in which all kinds coincide. The active vegetating force that resides in it must be precise; its quantity must be exactly proportioned to the nature, solidity, trisuity, quantity, and resistance of the ductile matter through which it passes; and these combinations are very different in different subjects: besides, times and circumstances produce a change in it, which is a source of variety, even during the time of gestation. Thus, the specific semen of one animal can never be moulded into another, and seeds may differ specifically from one another by many invisible principles totally unknown to us, and unobtainable by experiments; so that there is no danger of falling into equivocal generation; however, their principles, though capable of diffusing combinations, admit only of a limited variation, and never deviate farther than is consistent with univocal generation. Mr. Needham also observes, that the animalcules in the semen of animals, and in the infusions and juices of animal and vegetable substances, are not of the nature of any other beings, or to be ranked with them; that they constitute a class apart from all others, the characteristic of which is, that they are neither generated nor subsist by nutriment, as other plants and animals do, nor generate in the ordinary way. Of this class, he apprehends, is that species of polype, called the seed animal, owing its formation to the decomposition of some water plant, but approaching towards the nature of other animals, as, when once generated, it eats, and even generates as other animals do. He closes his system with observing, that the lower this new class of beings is pursued, the less was its vegetating force impeded by resisting matters; that the degree of exaltation in the matter from which they were formed was always the higher, and their motion the swifter; and he hence conjectures, that an animal substance may be exalted this way into a poison, or a contagious vapour; and that in this way flagrant waters become poisonous, and that even the poison of the viper, and other such animals may be owing to the same principles; nay, that this vegetable active force, when confined, may be the spring of all the mechanical forces of the body, and of the impressions which affect the soul.

Mr. Needham's system may be summed up in a few words: he supposes all semen of any kind to be an exalted portion of animal or vegetable matter, secreted from the aliment of every generating subject, when it is adult, and no farther exalted is made for its increase or growth; this is endowed with a proportionable vegetative force; and is various in various circumstances, and heterogeneous in different subjects, but uniform in its productions, when it falls into a proper matrix, where it finds matter to assimilate of a proper quality, and in a quantity sufficient to form that specific being; whilst in other circumstances, it will, if it extravasates, by the same vegetating force, produce the several phenomena which he has ascribed to it. Phil. Trans. vol. xiv. p. 615, &c.

GENERATION OF MAN. As it is in human subjects that the gradual process of generation has been principally inquired into, and the structure and office of the organs subservient thereto, chiefly examined: what the latest naturalists and anatomists have testified with regard to it, is referred to this head.

The parts of generation, then, are different in the different sexes. Those proper to the male, are the penis, the testicles, the vesiculae seminales, the vasa deferentia, the parastatae and the vasa preputiorum; which see described each under its proper article, PENIS, TESTICLE, &c. The parts of generation proper to the female are the VULVUM, the CLITORIS, HYMEN, UTERUS, VAGINA, FALLOPIAN TUBES, and OVARIES or TESTES.

The process of generation, so far as the male contributes to it, is as follows. The penis being erected by an afflux of blood; as shown under ERECTION; the glands at the same time turgid; and the porous papillae in the glans much rubbed, and highly excited, in coitus; an ejaculatory contraction follows, by which the seed is pressed out of the seminal vesicles, and expelled with some considerable force.

The process of generation on the one part of the female is thus: the clitoris being erected, after the like manner as the penis in man; and the neighbouring parts all distended with blood; they more adequately embrace the penis in coitus; and by the immiscence, press out a liquor from the glands about the neck of the womb, to facilitate the passage of the penis.

At the same time, the fibres of the womb, contracting, open its mouth (which at other times is extremely closed) for the reception of the finer part of the seed.

Thus the seed pregnant with animalcules, is conveyed, with some impetus, into the uterus: where being retained by the convulsive restriction of the inner membrane thereto, and farther heated and agitated therein, it is prepared to impregnate the ovum.

During the act of coition, the Fallopian tubes, expanding, embrace the ovaries with their strong muscular edges, like fingers, and compress them, till their mouths being dilated and expanded by this embrace, force the egg now ripened, into their cavities, and gradually drive it forwards, by their vermicular motion, till at last they protrude it into the cavity of the womb to meet the seed, some of the animalcules whereof, entering the dilated pores of the glandular membrane of the egg, are there retained, nourished, grow to its novel, and suffocate the rest of the less lively animalcula. And thus is conception performed.

Others rather suppose the seed conveyed from the uterus, through the Fallopian tubes, to the ova; and thus take the impregnation to be first performed in the ovaries; or even in the tube themselves, the ova and seed meeting by the way.

Others, considering the closeness of the mouth of the womb, and the thickness of the membranes of the ovaries, judge it impossible for the seed to pass that way; and therefore suppose it is taken up by the veins which open into the cavity of the vagina, or even the womb; where circulating, it ferments with the mass of blood; and hence all the symptoms which appear in conception.

At length it enters and impregnates the egg; by the small twigs of arteries which are upon its membrane. This fermentation swelling the membranes of the tube, they open the cavity, and make room for the ova to pass into the womb.

The egg impregnated, and close shut up in the womb, swims in the humours thereof; which, growing more and more labile, enter the patent pores found on one side the ovum, and soon disengage, fill and augment it; and there being still farther attenuated, nourish the embryo; thicken and expand the membranes of the ovum, especially in that part by which it grew to the ovary; and thus form the rudiments of a placenta.

The same causes still continuing, and the pores both of the placenta and the membranes being enlarged; the egg begins to fill the capacity of the womb; and at length its stem or calyx grows to the concave surface thereof; and thus is the navel-string, or funiculus formed. See FETUS and Funiculus UMBILICALIS.

This system is founded on the supposition of animalcula in the male seed. They who let them aside as unconcerned in generation, account for it thus: the seed, containing volatile, oily, and saline parts, as appears from its fetid smell, oleaginous substance, &c. being lodged in the womb, and there further digested and exalted, grows yet more volatile, feid, pungent and stimulating; and thus, adding to the heat occasioned by coition, vitiates the nervous fibres of that part, and occasions a fermentation, and gentle inflammation; and by that means an extraordinary flux of humours to that, and the adjacent parts.

By this means the tubes become rigid, and fit to grasp the ovaries, which are also heated by the effluvia of the semen and the warmth of the parts surrounding. Upon this there is a greater flux into the ovaries; till at length, the ova, some of them at least, by such greater supply of nourishment, increase in bulk; and as those grasped by the edges of the tube will be kept warm, and the greatest flux be made thence, they will soonest be ripened, fall off, and be received by the tube, and conveyed to the womb; where growing, after the manner of the seeds of plants, the placenta at length takes hold of, and adheres to, the uterus; from which time the embryo begins to be nourished after a different manner. See GENERATION, NUTRITION and CIRCULATION.

GENERATION OF FISH, FISHES, INFUSILS, METALS, MINERALS, MAMMALS. See FISH, FOSSILS, INSECTS, &c.

GENERATION OF PLANTS. See GENERATION OF PLANTS. See also FERINA, FLOWER, FRUCTIFICATION, PISTIL, and STAMINA.

GENERATION OF JUSLIS. See SHELLS.

GENERATION OF STONES. See STONES, SPAR, TROCHILITES, and CRYSTALS.

GENERATION, in Mathematics, is used for formation or production. Thus we meet with the generation of equations, curves, solids, &c.

GENERATION, in Theology. The father is said by some divines, to have produced his Word, or Son, from all eternity, by way of generation; on which occasion the word generation raises a peculiar idea: that procession, which is really effected in the way of understanding, is called generation, because in virtue thereof, the Word becomes like to him from whom he takes this original;—or, as St. Paul expresses

expresses it, is the figure or image of his substance, i. e. of his being and nature. See **TRINITY** and **PERSON**. And hence it is, they say, that the second Person in the Trinity is called the Son.

GENERATION is also used, though somewhat improperly, for **GENERALLY**, or the series of children issued from the same stock. Thus, the gospel of St. Matthew commences with the *beginning of Jesus Christ*, &c. The latter, and more accurate translators, instead of *generation* use the word *genealogy*.

GENERATION is also used to signify a people, race, or nation, especially in the literal translation of the scripture, where the word generally occurs wherever the Latin has *generatio*, and the Greek *γενος*, *γενος*.

Thus, "A wicked and perverse generation seeketh a sign," &c. "One generation passeth away, and another cometh," &c.

GENERATION is also used in the sense of an age, or the ordinary period of man's life.

Thus we say, in the third and fourth *generation*. In this sense, historians usually reckon a *generation* the space of thirty-three years, or thereabouts. See **AGE**.

Herodotus makes three *generations* in an hundred years; which computation appears, from the later authors of political arithmetic, to be pretty full. See **CHRONOLOGY** and **POLITICAL ARITHMETIC**.

GENERAL names, in *Natural History*, the word used to signify all the species of natural bodies, which agree in certain essential and peculiar characters, and therefore all of the same family or kind; so that the word used as the *general* name equally expresses every one of them, and those other words expressive of the peculiar qualities or figures of each are added, in order to denote them singly, and make up what is called the *specific* name.

Thus the word *rose*, or *rose*, is the *general* name of the whole series of flowers of that kind, which are distinguished by the specific names of the red *rose*, the white *rose*, the apple *rose*, &c. The ignorance of former ages, in the true principles of natural history, has occasioned the bodies, which are the objects of it, to be arranged into very unnatural series under the name of *genera*; and these have been called by names as improper as the characters they were distinguished by. Linnaeus has done a great deal in exploding the bad *general* names in *botany*; and Arndt has applied his rules about the formation of these names, with very little difference to the subjects of *ichthyology*.

Many of the *general* names of fish, till the time of this author, were so barbarous and obscure, that it was not easy to trace them to their original, or to find whether they were truly Teutonic, English, Dutch, Swedish, French, Italian, Spanish, Portuguese, Latin, or Indian. The ignorance of the writers on these subjects, or their too scrupulous adherence to the customs of their predecessors, seem to have been principally the causes of this, and often an entire negligence. Arndt's rules for *general* names for fish are these: wherever fish there are which agree in the same *general* characters, and are properly of the same genus, these ought all to be called by the same *general* name, their differences being only expressed by specific ones. This appears so plain, so just, and so necessary a rule, that it is almost a shame to lay it down; yet the writers on fish, till the time of this author, had very seldom observed it.

Another barbarian and impropriety in the *general* names of fish among the old authors, is the using of the same words to express them, which are also the names of other animals, quadrupeds, birds, and reptiles. These are subject to great objection; because when they are used, it is not easy to see, in some cases, whether the author is speaking of a bird, a beast, or a fish. It is therefore one of the general rules of Arndt, that all these names are to be abolished, as also all those which are common to fish, and to plants, minerals, and to the tools of husbandry, or other services.

Another rule of this excellent author is, that *general* names that are composed of two whole words, unnaturally tied together, are to be abolished, it being easy to contrive names less barbarous, and as expressive: next to these are to be exploded those names which are formed of two *general* words before in use, the one broken or cut short, the other preferred entire.

Another general rule in regard to these names is, that all such as are not of either Latin or Greek origin, are to be prohibited and wholly rejected. This rule cuts off a prodigious number of barbarous words, with which we find the books of authors of former ages on these subjects crowded.

A sixth rule for the regulating *general* names is, that all such as are to be abolished as terminative in *sensu*, as expressing a resemblance often imaginary, and often alluding to something unknown, or rendered difficult to trace from the changes which the names of other things have

undergone since the time when it was formed. These words convey no idea of the character of the genus expressed by them, except that they are like the other thing alluded to in some external, though perhaps not essential character: of this kind are the rhomboides, leptoides, &c.

A seventh rule in regard to these names is, that all such as are to be rejected as are barely diminutives, and terminative in *sensu* or *sensu*. These convey no other idea, but that of the fish being like some other fish, only less; now *bignonia* is no *general* character; therefore if this genus, and that referred to, differ only in size, they have no *general* difference at all; if they do differ otherwise, they should be expressed. What makes many of these names also more intolerable is, that they allude not to fish, but to other things so different in their nature, that there must needs be many other more essential varieties between them, beside size.

Another general rule is, that such *general* names as are pure Latin, but are mere adjectives, are to be exploded, there being no reason for using them as substantives.

A ninth general rule is, that such names as are formed of Latin words, unknown to the ancient Romans, and formed by the later writers, are to be expelled as barbarous, and others of better credit placed in their stead.

Finally, such *general* names as have been given to fish from the places where they are said to be rejected; of this kind are the *farfelli* and *faridini* from the island of Sardinia, and the *sturio* from Astura, a province of Spain. These sorts of names can convey no idea of the nature of the fish, and may belong as well to one genus as to another. Arndt, *ichthyolog.* p. 10, 69, 73, 79.

These rules of propriety in the names of fish, that might be supposed the whole number was exhausted, and all the fish in the world to be named anew. But this is not the case; the *genera* are in reality much fewer in number than they have been usually supposed, and therefore fewer words will serve to express them, and there yet remain many truly Latin words used by the ancient Romans, by which the far greater part of the *genera* may be expressed, and the few remaining may be best denominated by compound Greek words, expressive of their real characters. Among the true and genuine Latin, and Græco-Latin names of the *genera* of fish, are these: accipiter, amia, anthias, balanus, blennius, clupea, cobitis, cyprinus, delphinus, elope, elos, exocoetus, gobius, labrus, lamia, liparis, mugil, mulius, murena, perca, phyloter, prutis, raja, salmo, salpa, scarus, scomber, glanis, sparus, squallus, thynnus, torpedo, triton, turio, uranoscopus, xiphias, zeus. These will go a great way toward the naming the true *genera*. Arndt has merited greatly of the world, in thus reforming the names of fish; and the rules he has laid down, thus given at large, may, with little variation, be made to serve for any other author, in whatever branch of knowledge he has occasion to write.

GENERIS found. See **SECOND**.

GENEROSA, a gentleman. See **GENTLEMAN** and **SPINSTER**.

GENESIS, the first book of the Old Testament, containing the history of the creation, and the lives of the first patriarchs.

The book of *Genesis* stands at the head of the Pentateuch. Its author is held to be Moses: it contains the relation of a 300 years, viz. from the beginning of the world to the death of Joseph. The Jews are said to read the beginning of *Genesis*, and the beginning of *Ezekiel*, before thirty years of age.

The Hebrews called this book *bereshith*, because it begins with that word, which in their language signifies *in principle*, or *in the beginning*. The Greeks gave it the name *Genesi*, *genesis*, q. d. production, generation; because it begins with the history of the production or generation of all beings.

This book, besides the history of the creation, contains an account of the original innocence and fall of man; the propagation of mankind; the rise of religion; the general defection and corruption of the world; the deluge; the restoration of the world; the division and peopling of the earth; and the history of the first patriarchs to the death of Joseph. It was easy for Moses to be furnished of the truth of what he delivers in this book, because it came down to him through a few hands: for, from Adam to Noah, there was one man, viz. Methuselah, who lived so long as to see them both; in like manner Shem conversed with Noah and Abraham; Isaac with Abraham and Joseph, from whom the records of this book might easily be conveyed to Moses by Amram, who was contemporary with Joseph. Patrick.

GENESIS, in *Geometry*, denotes the formation of a line, plane, or solid, by the motion or flux of a point, line, or surface. See **FLUXION** and **CURVE**.

The *genius*, or formation, e. gr. of a globe or sphere, is conceived by supposing a femicle to revolve upon a right line, drawn from one extreme thereof to the other, called its axis, or axis of circumvolution: the motion or revolution of that femicle is the *genius* of the sphere, &c. See *GLOBE*.

In the *genius* of figures, &c. the line or surface that moves is called the *describer*; and the line round which, or according to which, the revolution or motion is made, the *divergent*.

GENET, or *Jennet*, said to be derived from *genet*, *lens natui*, in the *Mungy*, &c. a small-sized, well proportioned Spanish horse.

Some also give the term *genet* to well-made Italian horses. To ride a *GENETTA*, is to ride in the Spanish fashion, i. e. with the stirrups so short, that the spurs bear upon the flanks of the horse. This is deemed a piece of gallantry in Spain, but not among us.

GENETHLIA, *Tesha*, in *Indulgy*, a solemnity kept in memory of some person deceased.

GENETHLIACI, in *Astrlogy*, persons who erect horoscopes, or pretend to foretell what shall befall a man, by means of the stars which presided at his nativity.

The word is formed of the Greek *genos*, origin, generation, nativity.

The ancients called them *Chalalai*, and by the general name *mathematici*; accordingly, the several civil and canon laws, which we find made against the mathematicians, only respect the *genethliaci*, or astrologers.

They were expelled Rome, by a formal decree of the senate; and yet found so much protection from the credulity of the people, that they remained therein unmolested. Hence an ancient author speaks of them as *benignus genas*, and in *eccelesia nostra semper & vultu, & tractantur*.

Antipater and Aeschinopolus have shown, that *genethliaci* should rather be founded on the time of the conception than on that of the birth. Varron.

GENETHLIACUM, *GENETHLIACIUM*, is a composition in verse, on the birth of some prince, or other illustrious person; wherein the poet promises him great honours, advantages, success, victories, &c. by a kind of prophetic prediction. Such is the eclogue of Virgil to Pollio, beginning,

Siculis Maja, paula majora canamus.

There are also *genethliac* speeches or orations, made to celebrate a person's birth-day.

GENETIDES, in *Natural History*, a name given by the ancients to the stone, more generally known under the name *enchymones*. This was the spar incruated on the tops and sides of subterranean caverns, which they supposed daily to bring forth more, and therefore gave the powder of it to women at the time of their lying-in, to promote their speedy delivery.

GENETTA, a small animal of the weasel kind. See *GENETTA*.

GENETTE, in the *Monney*, a Turkish bit, the curb of which is all of one piece, and made like a large ring, and placed over the liberty of the tongue. When they bridle a horse, they make his chin pass through this curb, which surrounds his beard. This sort of bit was much used at the court of France when *Guillet* wrote. See *GENET*.

GENETYLLIS, *Genetia*, in *Antiquity*, a solemnity celebrated by women in honour of *Genetyllis*, the goddess of that sex.

GENEVA, or GIN, a popular name for a compound water, which is, or ought to be, procured from the berries of the juniper-tree, distilled with brandy or malt-spirits. The word is formed from *genere*, the French name of the juniper-berrie.

The best *genet* we now have, is made from an ordinary spirit, distilled a second time with an addition of some juniper-berries; but the original liquor of this kind was prepared in a very different manner. It was a custom in the distilling of spirits from wort, or other fermented liquors, to add in the working some aromatic ingredient, such as ginger, cortex Winterana, or grains of paradise, to take off the bad flavour, and to give a pungent taste to the spirit. Among other things used with this intent, some tried the juniper-berries, and finding that they gave not only an agreeable flavour, but very valuable virtues also to the spirit, they brought it to a general custom, and the liquor sold under this name. The method of adding the berries was to the malt in the grinding: a proper proportion was allowed, and the whole was reduced to mast together, and worked in the common way. The spirit thus obtained was flavoured as *origene* with the berries, and exceeded all that could be made by any other method. Our common distillers leave out the juniper-berries entirely from the liquor they now make

and sell under that name. Our chemists have by them into the ferret, that the oil of juniper-berries, and that of turpentine, are very much alike in flavour, though not in price; and the common method of making what is called *genet* in London, is with common malt spirit, and a proper quantity of oil of turpentine distilled together. Shaw's Essay on DRILL, p. 7. See *DISTILLATION*.

GENEVIEVE, St. GENEVIEVE, or St. GENEVIEVE, fathers or religious of St. Genesvire, the name of a congregation of regular canons of the order of St. Augustine, established in France.

The congregation of St. Genesvire is a reform of the Augustine canons. It was begun by St. Charles Faure, in the abbey of St. Vincent de Senlis, whercof he was a member, in the year 1618.

In the year 1634, the abbey was made *claustrum*; and a general chapter, composed of the superiors of fifteen houses who had now received the reform, chose F. Faure confessor of the abbey of St. Genesvire, and general of the whole congregation. Such were its beginnings.

It has since increased very much, and it now consists of above a hundred monasteries; in some whercof the religious are employed in the administration of the parishes and hospitals; and in others, in the celebration of divine service, and the instruction of ecclesiastics in seminaries for the purpose.

The congregation takes its name from the abbey of St. Genesvire, which is the chief of the order, and whose abbot is the general thereof. The abbey itself took its name from St. Genesvire, the patronus of the city of Paris, who died in the year 510. Five years after her death, Clovis erected the church of St. Genesvire, under the name and invocation of St. Peter, where her relics are still preserved, her shrine visited, and her image carried with great processions and ceremonies, upon extraordinary occasions, as when some great favour is to be interceded for.

GENIAL, GENIALIS, an epithet applied by the ancients to certain sciences, whom they supposed to preside over generation.

They were thus called *a genialis*, from *genus*; or, according to the correction of Scaliger and Vollius, *a genialis*, *in genus*, *procreans*: yet *Festus* says, that they were also called *genialis*, which seems to require the former reading. M. Dacier, in a note, shews that *a genialis* has the sense of *warlike*.

Among the *genial* gods, *dei geniales*, says *Festus*, were water, earth, fire, and air, which the Greeks called *zemyntes*. The twelve signs were sometimes also ranked in the number; as also the sun and moon.

GENICULARIS, in *Botany*, a name used by some authors for the great garden vicia, called *gala*. See *EMAC. IND. 2*.

GENICULI, in *Botany*, the joints or knots which appear in the shoots of plants; whence botanists call those marked therewith *geniculate plants*.

GENIO-GLOSSI, in *Anatomy*, the name of a pair of muscles, proceeding inwardly from the fore-part of the lower jaw, under another called *genio-hyoides*, and which, enlarging themselves, are inserted into the base of the tongue. They serve to pull the tongue forward, and to thrust it out of the mouth.

The word is formed from *genus*, *mentis*, the *idea*; and *glossa*, *lingua*, the tongue.

GENIO-HYOIDEUS, in *Anatomy*, a muscle of the *ex hyoidis*, which, with its partner, is short, thick, and fleshy, arising from the internal parts of the lower jaw-bone, called the chin; and dilating themselves, are soon lessened again, and inserted into the superior part of the fore-bone of the *ex hyoidis*. These pull upwards and forwards the *ex hyoidis*, and assist the *genio-glossi* in thrusting the tongue out of the mouth.

The word is formed from *genus*, *mentis*, the *idea*; and *hyoides*, *hyoides*.

GENIO-PHARYNGEUS, in *Anatomy*, is a name given by *Winflow* to a muscular portion, really distinct from the *genio-glossi*, inserted in the side of the pharynx, and joined to the *genio-glossi* all the way to the chin.

GENIPA, in *Botany*, the name of a genus of plants of the *pentandria monogyna* class, the characters of which are these: the flower is of the monopetalous kind, and is shaped like a bell, and very wide at the mouth: the pistil arises from the cup, and is fixed in the mummy of a nail to the hinder part of the flower. The cup finally becomes an oval fleshy fruit, divided into two cells, and containing a number of flattened seeds. There is only one known species of this genus, which is the oval-fruited *genipa* of authors.

GENISTA, in *Botany*. See *EROGIUM*.

GENISTELLA, in *Botany*, the name of a species of *genipa*. GENITA-mens, in *Mythology*, a goddess who presided over child-birth, to whom the Romans sacrificed a dog.

GENITAL,

GENITAL, GENITALIS, in *Anatomy*, something that relates to generation.

Genital parts denote the parts in both sexes employed in generation, otherwise called *actus*, *gubernatio*, or *procreatio*. See *Tub. Anat. (Spiral)*, p. 8, q. 30, 11, 12, 15, &c. See *PARIS, TESTICULI, CLITORIS, HYMEN, &c.*

GENITAL, *genit genialis*, are sometimes used in the ancient Roman poets for those we otherwise call *capitulum*.

GENITALIS, in the argument of the fourth book of the *Aeneid*, takes this word in a different manner; the *genitalis*, he observes, were such as were not born of human parents, and were not thus called *quasi geniti ex hominibus*, but rather because they themselves had begot human children.

GENITALIA, or **GENITORIA**, in *Anatomy*, a name sometimes given to the testes or testicles of a man, on account of their office in generation.

GENITED, in *Grammar*. See **GENERATED**.

GENITES, *Tyones*, or **GENETI**, among the *Hebrews*, those that descended from Abraham, without any mixture of foreign blood.

The Greeks distinguished by the name of *geniti* such of the Jews as were issued from parents, who, during the Babylonish captivity, had not allied with any gentile family.

GENITIVE, in *Grammar*, the second case of the declensions of nouns.

The relation of one thing considered as belonging in some manner to another, has occasioned a peculiar termination of nouns, called the *genitive* case.

In English, the *genitive* case is made by prefixing the particle *'s*, in French, *de*, or *du*, &c. though, in French, there are no cases at all, or at most only two, in either of those languages, inasmuch as they do not express the different relation of things by different terminations, but only by additional prepositions. See *CASE*. In the Latin, this relation is expressed in divers manners, thus we say, *caput hominis*, the head of a man; *color regis*, the colour of a king; *opus Dei*, the work of God, &c.

As the *genitive* case serves to express very different, and even opposite relations, there sometimes arises an ambiguity therefrom; thus, in the phrase *valetudo Achillis*, the wound of Achilles, the *valetudo*, *Achillis*, may either signify passively the wound Achilles has received, or actively the wound Achilles has given; thus, in this passage of St. Paul, *Corin. sum quod vobis mori, vobis vitam*, &c. *non potest separare a charitate Dei in Christo*, &c. the *genitive*, *Dei*, has been taken by interpreters in two different senses: some, giving it the relation of object, understood the passage of the love which the elect bear to God in Jesus Christ; whereas others give it the relation of subject, and explain it of the love which God bears the elect in Jesus Christ.

In the Hebrew tongue, the *genitive* case is marked after a manner very different from that of the Greek and Latin; for whereas in those languages the noun governed is varied, in the Hebrew the noun governing undergoes the alteration.

GENITURA, GENITURA, a name which some authors give to the *SEXU*, both that of the male and female.

GENITURA, in *Botany*, a name given by some authors to the antherum or *STAMEN*. A plant common in gardens, and used in medicine and cookery.

GENIUS, in *Metaphysics*, a good or evil spirit, or demon, whom the ancients supposed fell over each person, to direct his birth, accompany him in life, and be his guard, until death. Those that attended women were females, and called *Jannae*, but those that attended men were males, and called *Genii*. They seem, in their original, to be nothing else but in particular bent and temper of each person's soul; and as every man's own temper is to a great measure the cause of his happiness or misery, each of these were supposed to thence, and have an equal feeling in all the enjoyments and sufferings of the persons they attended. See *HORACE*, lib. ii. ep. 2. ver. 185. The ancients had their *Genii* of nations, of cities, of provinces, &c. Nothing is more common than the following inscription on medals: *GENIUS POPULI ROMANI*, the Genius of the Roman people; or, *GENIO POP. ROM.*, to the Genius of the Roman people.

In this sense, *genius* and *lar* were the same thing, as, in effect, *Genius* and *Apothanas* signify they were.

The Platonists, and other eastern philosophers, supposed the *Genii* to inhabit the vast region, or extent of air, between earth and heaven. They were a sort of intermediate powers, who did the office of mediators between gods and men. They were the interpreters and agents of the gods; communicated the will of the deities to men; and the prayers and vows of men to the gods. As it was unbecoming the majesty of the gods to enter into low trifling concerns, this became the lot of the *Genii*,

whose nature was of a middle kind, between the two; who derived immortality from the one, and passion from the other; and who had a body framed of an aerial nature. Most of the philosophers, however, held that the *genii* of particular men were born with them, and died. Thus Plutarch attributes the casting of oracles partly to the death of the *Genii*.

The heathens, who considered the *Genii* as the guardian spirits of particular persons, believed that they rejoiced and were afflicted at all the good and ill fortune that befell their wards. They were or very secretly appeared to them; and then only in favour of some person of extraordinary virtue or dignity. They likewise held a great difference between the *Genii* of different men; and that some were much more powerful than others; on which principle it was, that a wizard in *Apollonius* bids *Antony* keep at a distance from *Octavius*, because *Antony's Genius* was inferior to, and stood in awe of, that of *Octavius*.

There were also evil *Genii*, who took a pleasure in persecuting men, and bringing them evil tidings: such was that in *Paterculus*, &c. which appeared to *Brutus* the night before the battle of *Philippis*. These were also called *larvae* and *tormenta*. See *DEMONIUM*.

GENIUS is more frequently used for the force or faculty of the soul, considered as it thinks or judges.

Thus we say, a happy *genius*, a superior *genius*, an elevated *genius*, a narrow confined *genius*, &c. In like manner we also say, a work of *genius*, a want of *genius*, &c.

GENIUS is also used, in a more restrained sense, for a natural talent, or disposition in one thing more than another. In which sense we say, a *genius* for verse, for mathematics, &c.

For the difference between *genius* and *talent*, see *TALENT*.

GENOA *Genova*, in *Anatomy*, the name of a famous composition, called also the *Saliva of Apollonius*. In great virtues are the cutting pains in the extremities of the body, and allaying the violent pains in the bowels, to which many women are subject after delivery. The prescription is given at large in *Vellicus*, but the medicine is now out of use.

GENSDARMES. See **GENDARMES**.

GENTIAN, or **FELLOWORT**, *Gentiana*, in *Botany*, a genus of the *pentandria digynia* class. Its characters are these: it hath a permanent empanclement to the flower, cut into five acute segments; the flower hath one petal, which is tubulosity, and cut into five flat parts at the top; it hath five awl-shaped stamens, shorter than the petal, terminated by single funiculi; in the centre is situated an oblong, cylindrical germen, having no style, but crowned by two oval stigmas, which afterward becomes an oblong taper-pointed capsule with one cell, containing many small seeds fastened to the sides of the capsule. There are twelve species, one of which is the common *gentian* of the Rhone, whose root is one of the principal ingredients in bitterness; it grows naturally in the pastures in Switzerland, and in the mountainous parts of Germany; from whence it is brought to England for medicinal use.

The ancients, to render it the more considerable, denominated it from *Gentius*, king of *Byzantium*, who is supposed to have been the first that discovered the admirable virtues of this plant.

The root *gentian* is of a yellowish colour, and extremely bitter; it is sometimes as thick as the arm, but more commonly divided into branches no bigger than the thumb: its stem grows several feet high, being very smooth and glossy, though divided by knots from space to space, out of which arise the leaves, which somewhat resemble those of poplars. Its flowers, which likewise accompany the knots, are yellow; and its seed is flat, round, smooth, and light.

The root is to be chosen dry, new, of a moderate thickness, free from earth, and furnished with little branches or fibres; and it is possible that which is dried by the air, which is distinguishable by the colour, it being blackish within, when dried in the oven; and of a golden yellow, when in the air.

This root is one of the best Rhomeic bitters in the materia medica; it procures an appetite, and greatly assists digestion. It has also been exalted as a scorbatic and alexipharmic, and as a certain remedy for the bite of a mad dog. On this occasion it is not only recommended internally but externally, in the form of a cataplasm, made of Venice treacle, and the powder of this root, applied to the wound. An ounce of the *gentian* root, with the same quantity of fresh lemon-peel, and a dram and a half of dried orange-peel, infused for an hour or two in three quarters of a pint of boiling water, make a very elegant bitter. The bitter *fructus* are commonly prepared by macerating the above quantity of the root, for some days, in a pint of proof spirit, with four drams of dried orange-peel, and two of lesser custardum seeds. See *Stomachicis* *ELIXIRS*.

Wines and malt liquors are likewise impregnated with the virtues of this root in different proportions. An ounce of the *gentian* root, the same quantity of fresh lemon-peel, and two drams of long pepper, communicate by maceration, without heat, a grateful warmth and bitterness to a quart of mountain. The virtue of the root is extracted by all these menstria, and also by rectified spirit. The tincture in rectified spirit is of an orange-yellow colour; inspissated, it yields an intensely bitter extract: the watery infusions are of a dark brownish red; and leave, when inspissated, an extract, in larger quantity, but less bitter, than the other. These extracts are made into pills, with or without aromatic additions. There is an Indian *gentian* brought from America by the Portuguese, of a pale yellowish colour, jointed and marked with knots and circles like ipseosamba, more intensely bitter than any of the official bitter drugs. This root is greatly commended in obdurate intermittents, and other disorders; a scruple is said to be more effectual than repeated half drams of bark.

There was a mixture of henbane root brought over some years ago with the common *gentian*, which occasioned violent disorders, and, in some instances, proved fatal. This root is of a pale colour than *gentian*, and its longitudinal wrinkles finer and closer; the poisonous root, when cut, appears white, without any degree of the yellow hue, which is deep in *gentian*; and its taste is not bitter, but mucilaginous. *Lewin's Mat. Med.*

GENTIANAE RADIX. See WATER.

GENTIANA nigra, a name given by some botanical authors to the mountain *DAUCUS*, or black *hiansia*.

GENTIANELLA, little *gentian*, a diminutive of the name *gentiana*, commonly applied to the smaller species of *gentian*, or the broad-leaved Alpine *gentian*, with a large flower.

GENTILE, GENTILI, a pagan, or person who adores false gods. The Hebrews applied the name גִּתִּיל, *gentil*, *gentili*, to all the people of the earth who were not Israelites or Hebrews.

Some will have it that the *gentile* were thus called in contradistinction to the Jews, because the latter had a positive law to observe in matters of religion, whereas the *gentile* had only the natural law; hence they are called *gentile*, *quia sunt uti gentili fuerunt*, because they remain as in a state of nature.

The Jews apply the denomination *gentile* much as the Christians do that of infidels. St. Paul is called the *doctor*, or *apostle of the gentile*, which appellation he first gave himself, Rom. xi. 13. "As I am the apostle of the *gentile*, I magnify mine office."

The calling of the *gentile* to Christianity has been predicted in the Old Testament, as it was accomplished in the New. See Psal. li. 8. Isa. li. Joel ii. 29. Math. viii. 11. xii. 18. Acts. ii. 18. xiii. 47. 48. xxviii. 28. Rom. i. 5. xii. 10. 13. 14. 25. Eph. ii. 11. Rev. x. 2. xxi. 2.

GENTILE, GENTILI, in the Roman Law and History, a name which sometimes expresses those whom the Romans otherwise call *Barbarians*; whether they were allies of Rome, or not. In which sense the word occurs in Ammianus, Ausonius, and the Notitia Imperii.

GENTILIS was also used, in a more peculiar sense, for all strangers, or foreigners, not subject to the Roman empire; as we see in the Theodosian Code, in the title De Nuptiis Gentilium; where the word *gentilis* stands opposed to *premiarius*, or the inhabitants of the provinces of the empire.

The word is likewise used, in this sense, in the Greek; but it was not introduced either into that, or the Latin tongue, till after Christianity was established; it being taken from Scripture.

GENTLITIA Jura, among the Romans. See SACRA.

GENTLITIUS, an epithet used by some authors, to express *miscellaneous*, propagated from father to son, and running through whole families; such as are more usually called hereditary disorders. Such is the gout very frequently, and often many others.

GENTLE pit ore, in Mineralogy, a name given by our miners in Suffolk, to a kind of iron ore found in considerable plenty in that county, and very readily running in the fire, though not over rich in metals. It is a shining substance, and lies in several parts of that county in form of a moderately thick stratum. It is of a dusky brown colour, and in some places much paler than in others. It hath always a great number of glittering fragments in it, and very often contains fossil shells, and other extraneous substances in it.

GENTLEMAN, a person of good family, or descended of a family which has long borne arms, the grant of which adds gentility to a man's family.

The word is formed of the French *gentilhomme*, or rather of *gentil*, fine, fashionable, or becoming; and the Saxon *man*, q. d. *lord*, or *house* has *man*. The same signification has the Italian *gentiluomo*, and the Spanish *ca-*

dalge, or *hijo dalge*, that is, the son of somebody, as is a person of note. If we go farther back, we find that *gentleman* originally derived from the Latin *gentilis*, which was used among the Romans for a race or noble persons, of the same name, born of free or immemorial parents, and whose ancestors had never been reduced to death by law. Thus Cicero, in his *Tullius*, *gentilis fuit, qui inter se velut fratres amicitia amicitiaqueque majorum nexu societatem forebat, qui capite non sunt amittendi*, &c. Some hold, that it was formed from *gentile*, i. e. *pages*; and that the ancient Franks, who conquered Gaul, which was then converted to Christianity, were called *gentiles* by the natives, as being yet barbarians. Others relate, that towards the declension of the Roman empire, as recorded by Ammianus Marcellinus, there were two companies of brave soldiers; the one called *gentilium*, and the other *frankorum*; and that it was hence we derived the names *gentleman* and *esquire*. This sentiment is confirmed by Paquier, who supposes the appellation *gentilis* and *esquiers* to have been transmitted to us from the Roman soldiery; it being to the *gentilium* and *saturii*, who were the bravest of the soldiery, that the principal benefices, and portions of lands, were assigned. See BENEFICE. The Gauls observing, that, during the empire of the Romans, the *saturii* and *gentilis* had the best tenements, or appointments, of all the soldiers on the frontiers of the provinces, became insensibly accustomed to apply the same names, *gentilium*, and *esquiers*, to such as they found their kings gave the best provisions or appointments to. Paquier. Rech. lib. ii. cap. 45.

In strictness, Chamberlayne observes, a *gentleman* is one whose ancestors have been freemen, and have owed obedience to none but their prince: on which footing, no man can be a *gentleman* who is not born so. Among us, the term *gentleman* is applicable to all above yeomen; so that noblemen may be properly called *gentlemen*.

In our statutes, *gentilis homo* was adjudged a good addition for a *gentleman*, 27 Edw. III. The addition of knight is very ancient; but that of *esquire*, or *gentleman*, was rare, before Henry V.

We read that J. Kingdon was made a *gentleman* by king Richard II.

As it may justly be asked, what constitutes a *gentleman* with us? the reply is easy; being a *gentleman*, is being entitled to bear arms. And Mr. Camden observes, that the distinction of a *gentleman* of countenance, or an upstart, and a *gentleman* of blood, is the bearing of arms from the grandfather; and that he who bears arms from his grandfather, is to all intents and purposes a *gentleman* of blood; for which cause it is requisite by the statutes of the Bath, that every knight before his admission, proves himself to be so qualified; which done it carries with it, if his merit be equal, a passport also to the order of the Garter. Notitia Anglicana, p. 24. See also Doddridge's Honour's Pedigree, p. 147. Smith, De Rebus Angl. & Foreisicis, fol. 34.

Guillim, in his chapter of *Gentlemen*, says, that they have their beginning either of blood, as being born of worshipful parents; or that they have done something, either in peace or war, whereby they deserve to bear arms, and be accounted *gentlemen*. He farther says, chap. xxv. if a *gentleman* be bound apprentice to a merchant or other trader, he hath not thereby lost his gentility; and he desires it may be remembered, for the honour of trade, that king Henry VIII. thought it no dishonour to him, when he quitted his queen, to take to his wife Anne, the daughter of Thomas Bullen, some time mayor of London. To which may be added the thought, that the first William, who founded our royal race, was the grandson of a tanner.

Sir Edward Coke says, that *esquires* and *gentlemen* are only names of worship, and not of dignity. And before these the heralds rank all colonels, sergeants at law, and doctors in the three learned professions. See PREFERENCE.

GENTLEMAN of the black rod. See BLACK.

GENTLEMAN of the chamber. See BED-CHAMBER.

GENTLEMEN of the chapel, are officers whose duty and attendance is in the royal chapel, being in number thirty; ten whereof are priests, and the other twenty called *clerks of the chapel*, who assist in the performance of Divine service. One of the first ten is chosen for confessor of the household, whose office it is to read prayers every morning to the household for many, to visit the sick, examine and prepare communicants, and administer the sacrament.

Another, well versed in music, is chosen first organist; who is master of the children; to instruct them in music, and what is necessary for the service of the chapel; a second is likewise an organist; a third a fiddler; and a fourth a violist.

There

There are likewise three *sargars*, so-called from the silver rods they usually carry in their hands; being a friar, a young man, and groom of the stable; the first attends the dean, and sub-dean; finds, furnishes, and other necessities for the chapel; the second has the whole care of the chapel, keeps the pews, and feeds the nobility and gentry; the groom has his attendance within the chapel-door, and looks after it.

GENTLEMAN, *see* PENSIOSITY.

GENTLEMAN, GENEKOSA, is a good addition for the estate and degree of a woman, as *gentes* is for that of a man; and if a *gentleman* be named *gentes* in any original writ, appeal, &c. it hath been held that he may abate, and quash the same. 2 Inst. 668.

GENTOOS, in *Modern History*, according to the common acceptance of the term, denote the professors of the religion of the bramins, or BRACHMANA, who inhabit the country called Hindostan, in the East Indies, from the word *jan*, a region, and *hind* or *hindus*; which Terribach, as we learn from colonel Dow's translation of his History, supposes to have been a son of Ham, the son of Noah. It is observed, however, that Hindoo is not the name by which the inhabitants originally styled themselves, but, according to the idiom of the SHANSCRIT, which they use, *jambudwip*, from *jambus*, a jackall, an animal common in their country, and *dewp*, a large portion of land surrounded by the sea, or *dwarcadwip*, from *dwant*, i. e. a continent, and *dwart*, the name of one of the first Indian rajahs. It is also observed, that they have assumed the name of Hindoo only since the era of the Tartar government, to distinguish themselves from their countrymen, the Mussulmen. The term *Gento*, or *Gen*, in the ShanSCRIT dialect, denotes animal in general, and in its more confined sense mankind, and is never appropriated particularly to such as follow the doctrines of Brhmin.

These are divided into four great tribes, each of which has its own separate appellation; but they have no common or collective term that comprehends the whole nation under the idea affixed by the Europeans to the word *Gento*. Mr. Halhed, in the preface to his translation of the Code of Gentoo Laws, conjectures, that the Portuguese on their first arrival in India, hearing the word frequently in the mouths of the natives, as applied to mankind in general, might adopt it for the domestic appellation of the Indians themselves, or, perhaps, their bigotry might force from the word *Gento* a fanciful allusion to gentile or pagan. The Hindoos, or *Gentos*, vie with the Chinese as to the antiquity of their nation. They reckon the duration of the world by four jogues, or distinct ages; the first is the Sattve jogue, or age of purity, which is said to have lasted about 3,000,000 years, during which the life of man was 100,000 years, and his stature twenty-one cubits; the second, the Tittah jogue, or the age in which one third of mankind were reprobate, which consisted of 2,400,000 years, when men lived to the age of 10,000 years; the third, the Dwapar jogue, in which half the human race became depraved, which endured to 600,000 years, when men's lives were reduced to a thousand years; and fourthly, the Collee jogue, in which all mankind were corrupted, or rather diminished, which the word *adha* imports. This is the present era, which, they suppose, will subsist for 400,000 years, of which near five thousand are already past, and man's life in this period is limited to a hundred years. It is supported by many authors, that most of the *Gento* MYSTERS, or scriptures, were composed about the beginning of the collee jogue; but an objection occurs against this supposition, viz. that the Bramins take no notice of the deluge, to which the Bramins reply, that all their scriptures were written before the time of Noah, and the deluge never extended to Hindostan. Nevertheless, it appears from the Bramins themselves, that they claim a much higher antiquity than this; instances of which are recited by Mr. Halhed.

The doctrine of transmigration is one of the distinguishing tenets of the *Gentos*. With regard to this subject it is their opinion, according to Mr. Holwell, that those souls which have attained to a certain degree of purity, either by the innocence of their manners, or the severity of their mortifications, are removed to regions of happiness, proportioned to their respective merits; but that those who cannot so far surmount the prevalence of bad example, and the powerful degeneracy of the times, as to deserve such a promotion, are condemned to undergo continual punishment in the animation of successive animal forms, until, at the stated period, another renovation of the four jogues shall commence, upon the dissolution of the present. They imagine six different spheres above this earth, the highest of which, called *sattve*, is the residence of Brhmin, and his particular favourite. This sphere is also the habitation of those men who never uttered a falsehood, and of those women who have voluntarily burned themselves with their husbands; the

prophecy of which practice is expressly enjoined in the code of the *Gento* laws. This code, printed by the East India company in 1776, is a very curious collection of Hindoo jurisprudence, which was collected by the most experienced pundits, or lawyers, from eastern originals in the ShanSCRIT language, who were employed for this purpose from May 1773 to February 1775; afterwards translated into the Persian idiom, and then into the English language, by Mr. Halhed.

The several institutes contained in this collection are interwoven with the religion of the *Gentos*; and revered as of the highest authority. The curious reader will discover an astonishing similarity between the institutes of this code and many of the ordinances of the Jewish law, between the character of the bramins or priests, and the Levites; and between the ceremony of the leap-year, under the Mosaic dispensation, and a *Gento* ceremony, called the *shumans* day, in which a horde answers the purpose of the goat. Many obsolete customs and usages alluded to in many parts of the Old Testament, may also receive illustration from the institutes of this code. It appears from the code, that the bramins who are the priests and legislators of the country, have resigned all the secular and executive power into the hands of another cast or tribe; and no brammin has been properly capable of the magistracy since the time of the latter jogue; the only privilege of importance which they have appropriated to themselves, is an exemption from all capital punishments; they may be degraded, branded, imprisoned for life, or sent into perpetual exile; but it is every where expressly ordained, that a brammin shall not be put to death on any account whatsoever.

We have already observed, that the Hindoos are divided into four great and original tribes, which, according to the *Gento* theology, proceeded from the four different members of Brhmin, the supposed immediate agent of the creation under the spirit of the Almighty. These tribes are the bramins, which proceeded from his mouth, and whose office is to pray, read, and instruct; the Chhetrees, which proceeded from his arms, whose office is to draw the bow, to fight, and to govern; the Sier, proceeding from the belly or thighs, who are to provide the necessities of life by agriculture and traffic; and the Booder from the feet, which are ordained to labour, serve, and travel.

Few christians, says the translator of the *Gento* Code, have expressed themselves with a more becoming reverence of the grand and impartial designs of Providence in all its works, or with a more extensive charity towards all their fellow-creatures of every profession, than the *Gentos*. It is, indeed, an article of faith among the bramins, that God's all merciful power would not have permitted such a number of different religions; if he had not found a pleasure in beholding their varieties. Those who are desirous of being further acquainted with the principles, manners, and various institutes of the *Gentos* may consult Holwell's interesting historical Essay, &c. 1766. Dow's History of Indostan, 4to. 1768; and the Code of *Gento* Laws. See also SHANSCRIT and VEDAS.

GENUFLEXION, of *genu*, knee, and *flexio*, I bend, the act of bowing, or bending; the knee or rather of kneeling down.

The Jewish Rabbins, in his Onomasticos, shews, that *genuflexion*, or kneeling, has been a very ancient custom to the church, and even under the Old Testament dispensation; and that this practice was observed throughout all the year, excepting on Sundays, and during the time from Easter to Whitsunday, when kneeling was forbidden by the council of Nice.

Others have shewn, that the custom of not kneeling on Sundays had obtained from the time of the apostles; as appears from St. Irenaeus, and Tertullian; and the Aethiopic church, scrupulously attached to the ancient ceremonies, still remains that of not kneeling at divine service. The Russians esteem it an indecent posture to worship God on the knees. Add, that the Jews usually prayed standing. Rabbins give the reason of the prohibition of *genuflexion* on Sundays, &c. from St. Basil, Anastasius, St. Justin, &c.

Baronius is of opinion, that *genuflexion* was not established in the year of Christ 38, from that passage in Acts. x. 25. where St. Paul is expressly mentioned to kneel down at prayer; but Saurin shews, that nothing can be thence concluded.

The same author remarks, also, that the primitive Christians carried the practice of *genuflexion* so far, that some of them had worn cravats in the floor where they prayed; and St. Jerome relates of St. James, that he had contracted a hardness on his knees equal to that of camels.

GENUS, in *Arith.* The ancient algebraists distributed that or into two *gours*, or kinds the *LOGICUS*, and *ARITHMETICUS*.

GENUS,

GENUS, in *Anatomy*. The *genus nervosum*, or *nervous* kind, or, as others say, the *nervous system*, is an expression pretty frequent among authors; signifying the nerves, considered as an assemblage, or system, of similar parts, distributed throughout the body.

GENUS, **GENERA**, in *Diversity*, denotes a system, or assemblage, of several plants, agreeing in some one or more common characters in respect of the structure of certain parts; whereby they are distinguished from all other plants.

The distribution of plants into *genus*, and species, is absolutely necessary to ease the memory, and prevent its being oppressed, and overburdened with an infinity of different names. The knowledge of a *genus* comprehends, in a kind of miniature, that of all the plants belonging thereto, each being denominated from some circumstance, common to the whole kind, to save the embarrassment of too many particular names.

Something like this, even the common people do, especially in the instance of manumales, &c. but in many other plants the difficulty is infinitely greater, as it is hard to find any thing is common among them, wherein as found the *genus*.

Hence botanists differ as to the manner of regulating the *genus*, and the characters wherein they are to be established. Mr. Ray's distribution, see under **PLANT**.

One of the late writers, Monk, Tournefort, after a long and accurate discussion, has chose, in imitation of Celsus and Columella, to regulate them by the flowers and fruits, considered together; so that all plants, which bear a resemblance in those two respects, are of the same *genus*; after which the respective differences, as to root, stem, or leaves, make the different species, or subdivisions. See **BOTANY**.

Mr. Ray made some objections to this distribution, which grew into a considerable controversy between the two authors. The question was, whether the flowers and fruits were sufficient to establish *genera*; and to determine whether a plant was of this *genus*, or that.

The same M. Tournefort introduces another higher kind of *genus*, or class, which is only regulated by the flowers. He observes, that he has never hitherto met with above fourteen different figures of flowers; which, therefore, are all that are to be retained in the memory: so that a person who has a plant in flower, whose name he does not know, will immediately see what class it belongs to, in his Elements of Botany; and the fruit appearing some days afterwards, determines its *genus* in the same book; and the other parts give its species.

It is a wonderful rule to the memory, to have only fourteen figures of flowers to retain, and, by this means, to be enabled to descend to six hundred and seventy-three *genera*, which comprehend eight thousand eight hundred and forty-six species of plants; which was the number of those then known by land and sea. The *genera* of plants, by the sexual system of Linnaeus, which is now generally adopted, are to be regulated by the **FRUCTIFICATION** only: so that all vegetables which agree in their parts of fructification are to be put together under one *genus*; and all that differ in those parts are to be separated. The characteristic mark of each *genus* is to be determined by the number, figure, proportion, and situation of all the parts; but as there are few *genera*, in which all the parts are constant in every one of the species, we ought, wherever it is possible, to fix upon some one single circumstance that is constant, and make it the essential character. There is, however, no one part of fructification that can be relied on as a constant characteristic mark of all *genera*; but in some, one part of the fructification is found to be the most constant; and in others, another the more constant any part of the fructification is found through the several species of any *genus*, the more it may be relied on with certainty as a characteristic mark for that *genus*. But if this characteristic mark is wanting, in any particular species, caution should be observed, lest *genera* should be confounded that ought to be distinguished; and when it is observed in some species of another *genus* near akin to it, care should be taken that the *genera* are not multiplied by parsing species that should really stand together. See Lee's *Introduct. to Botany*, p. 154, &c.

GENUS, **KIND**, in *Logic* and *Metaphysics*, is that which has several species under it; or it is the origin and radix of divers species, joined together by some affinity, or common relation, between them.

Genus is a nature, or idea, so common and universal, that it extends to other general ideas, and includes them under it.

Thus, animal is said to be a *genus*, in respect of man and brute; because man and brute agree in the common nature and character of animals; so a right lined figure, of four sides, is a *genus* in respect of a parallelogram, and a trapezium; and so, likewise, is substance, in respect

of substance extended, which is body; and thinking substance, which is mind.

A good definition, say the schoolmen, consists of *genus* and difference.

In the general, *genus* may be said to be a class, or *classis*, more extensive than species; and which is not convertible with it; for though we may say, that all body is substance, yet it cannot be said all substance is body.

Add, that whatever may be said of the *genus*, will be said of the species under it; e. gr. whatever is said of *ani*, being, will equally hold of the body.

The schoolmen define the *genus* *logice* to be, an universal which is predicable of several things of different species; and divide it into two kinds: the one, the *communis*, which is the highest, or most general; and has nothing above it to respect as a *genus*; the other the *subalternum*, which they likewise call *medium*.

Genus commune is that which holds the highest place in its class, or predicament; or that which may be divided into several species, each whereof is a *genus*, in respect of other species placed below it.

Thus, in the predicament of things subsisting of themselves, *substantia* has the place and effect of *genus commune*, and is predicated of all the things contained in that class: for both *Plato*, and man, and animal, and even *spiritus*, are properly called substance.

Accordingly, there are as many *commune genera*, as there are classes of predicaments, or categories.

Genus subalternum, is that which, being a medium between the highest *genus* and the lowest species, is sometimes considered as a *genus*, and sometimes as a species.

Thus, bird, when compared with animal, is a species; when to a crow, and eagle, or the like, it is a *genus*.

Genus, again, is divided into *remotum*, remote, where between it and its species there is another *genus*; and *proximum*, or next, where the species is immediately under it; as man under animal.

Genus is also used for a character, or manner applicable to every thing of a certain nature, or condition. In which sense it serves to make capital divisions in divers sciences; as music, rhetoric, botany, anatomy, &c. E. gr.

Genus, in *Music*, by the ancients called *genus musica*, denotes a certain manner of subdividing the principles of melody, i. e. the consonant intervals, into their constituent parts.

The moderns, considering the octave as the most perfect interval, and that where all the other concords depend in the present theory of music; the division of that interval is considered as containing the true division of the whole scale.

But the ancients went to work somewhat differently: the *diatessaron*, or fourth, was the least interval which they admitted as concord; and therefore they sought, first, how that might be most conveniently divided; from which they constituted the *diapente*, or fifth; and *diapason*, or octave.

The *diatessaron* being thus, as it were, the root, or foundation of the scale; what they call the *genera*, kinds, arose from its various divisions; and hence they defined the *genus mixtum*, the manner of dividing the *tetrachord*, and disposing its four sounds as to succession.

The Greeks constituted three such *genera* known by the names of **ENHARMONIC**, **CHROMATIC**, and **DIATONIC**. The enharmonic was not subdivided, but the chromatic was divided into three species, and the diatonic into two; so that the ancients had six species, or different divisions of the fourth in use. The moderns know but four, and one of these, the enharmonic, is scarce ever met with. It does not appear that the ancients themselves could accurately define these several species. Aristoxenus left it to the ear and practice, and did not pretend to assign any true proportions in numbers. However, he has attempted to convey some idea of these *genera* and species, by supposing the fourth divided into thirty parts. That is (as Ptolemy understands him) he supposes the difference of a chord and its fourth to be divided into thirty parts; and then assigns a certain number of these parts to each interval, or division of the various species. Hence the fourth, containing two tones and a half, the tones will each have twelve parts, and the semi-tone six.

In the enharmonic, he makes the interval between the hypate and parhypate, as also between the parhypate and the lichanos, to be a *dissema quadratum*, or $\frac{1}{4}$; and from the lichanos to the nete he makes a *tritone*, or $\frac{3}{4}$. So that the enharmonic divisions will be $3 + \frac{1}{4} + \frac{1}{4} = 3\frac{1}{2}$.

In the chromaticum molle, he makes the interval between the hypate and parhypate, as also from the parhypate to the lichanos a *tritone* diatonic, or $\frac{3}{4}$; and from the lichanos to the nete $\frac{1}{4}$; that is, an undivided interval equal to a tone, a semitone, and a tritone diatonic. Hence the intervals of this species will be represented by the numbers $4 + \frac{1}{4} + \frac{1}{4} = 5$.

In the chromaticum hemelium, or *semitonium*, he makes

makes

makes the interval from the hypate to the parypate, and from thence to the lichanus, a diesis *falsiquartera*, that is $\frac{1}{4}$ of the enharmonic diesis, or $\frac{1}{4}$ parts of his division of the fourth. The remaining undivided interval is of 21 parts, being equal to a tone, a hemitone, and a quadrantal diesis. This species will be represented by the numbers, $4\frac{1}{2} + 4\frac{1}{2} + 21 = 30$; or, to avoid fractions, $9+9+42=60$.

In the chromaticum tonicum, or *tonicum*, he makes the interval between the hypate to the parypate, and from thence to the lichanus, a hemitone, or $\frac{1}{2}$, and from thence to the nete, a tone and a half, or $1\frac{1}{2}$. Hence the species will be expressed by the numbers, $6+6+18=30$.

In the diatonicum molle, he makes the interval between the hypate and parypate a hemitone, or $\frac{1}{2}$, from thence to the lichanus $\frac{1}{2}$, and from this to the nete $\frac{1}{2}$; so that this species will be represented by the numbers $6+9+15=30$.

In the diatonicum intenfum or *syntonium*, the interval between the hypate and parypate is according to him a hemitone; and between the parypate and lichanus, as also between the lichanus and nete, is a tone. Hence the expression of this species will be $6+12+12=30$.

The same divisions are in Euclid; and Ptolemy gives the like proportions from Ariftozenus, only doubling the numbers to avoid fractions.

Ariftozenus does not pretend that the divisions he propounds are accurate. He seems to doubt of the diatonic being two tones and a half; and of its being at all measurable by any small interval, as the hemitone or diesis. He questions whether the enharmonic diesis be precisely the fourth part of a tone; or if the chromatic diesis be its third part; all which doubts are very well grounded. And it seems as if this famous musician had only proposed his divisions of the tetrachord, as approxi-

mations to convey some idea of the different species to the imagination; and not as an accurate standard to guide the voice, and hand, in singing and playing.

This is the doctrine of the ancients concerning their fix species of fourths. How to reconcile this to modern notions, and with the true principles of music, might be a work of some difficulty. Dr. Keppel has given us his opinion as to what their fix species would accurately be. How far his opinion is deducible from the remains of the ancient musicians, has not yet been publicly shown. We have mentioned his doctrine under the heads CHROMATIC, DIATONIC and ENHARMONIC, and shall here give them in one short view.

Intervals of the

Enharmonic, $12 = 4 + 8 + 11$.

Chromaticum molle, $12 = 1 + 1 + (3 + 9)$.

Chromaticum falsiquarterum, $12 = 8 + 4 + 3$.

Chromaticum tonicum, $12 = 8 + 8 + (7 + 1)$.

Diatonicum molle, $12 = 8 + 2 + (7 + 4)$.

Diatonicum intenfum, $12 = 8 + 4 + 7$.

To understand which, observe, that $\frac{1}{4}$ stands for the diesis enharmonic, $\frac{1}{2}$ for the semi-tone minor, $\frac{3}{4}$ for the semi-tone major, 1 for the tone minor, $1\frac{1}{2}$ for the tone major, 2 for the third minor, $2\frac{1}{2}$ for the third major, 3 for the fourth; and when two intervals are placed within a parenthesis, it signifies a single interval equal to the two joined by the sign of addition. Thus $(3+4)$ is an interval equal to the third minor and diatonic enharmonic; $(7+1)$ is equivalent to the tone major and semi-tone minor, commonly called a superfluous tone; and lastly $(7+4)$ signifies a tone major and diesis enharmonic, which interval, no more than $(3+4)$ has no particular name. Phil. Trans. N^o 421. p. 272.

Dr. Wallis has given us a synopsis of the *genera* and species according to Ariftozenus; we shall here insert it, as it gives light to the doctrine of the ancient tetrachords.

Generum Synopsis secundum Ariftozenum.

The gradual approach of the planets, in the different species, to the notes, shows why this chord was called *fiat*. The length of this scheme, or the side divided into thirty parts, is supposed to be the difference of any chord, and its fourth. Ptolemy takes these divisions in an ascending fourth; that is, the length of the two chords, or the whole of one chord, is terminated at *hypate*; and the termination of the shorter chord, or of that part of the long chord sounding a fourth to the whole, is at *nete*. So that we must imagine ninety parts added upwards to this scheme beyond *nete*; and then, for instance, the lengths of the chords, or parts of a chord representing the *diatonic tetraorch* of Aristoxenus, according to Ptolemy, will be 120, 114, 102, and 90. Ptolemy Harmon. page 92. Edit. Wallis in Oper. tom. iii.

But we must observe, that the ninety parts might be added downwards in the foregoing scheme, from *hypate*; and then we should have a descending fourth expressed by the following numbers, 90, 96, 108, and 120, which is most perfectly in tune, and gives us the *sonorous major*, the *tone major*, and the *tone minor*. For $7:4::120:90$ is the proportion of lengths of chords expressing the *sonorous major*, $7:3::120:96$ is in like manner a *tone major*, and $7:2::120:108$ is the expression of the *tone minor*. On the other hand, Ptolemy's numbers are much out of tune, and such as a musical life Aristoxenus dividing a string by his ear could not fall upon. We do not know that any commentator of the ancients ever made this observation; but if we pursue it through all the species, we shall find a very sensible difference in the expressions of the proportions of the various intervals found according to Ptolemy's manner, and those found in the way here mentioned, and exemplified in the *diatonic tetraorch*. Aristoxenus and his followers determined the several species, or divisions of the *musical* by intervals, making the whole *diatonic tetraorch* equal to two times and a half. But the Pythagoreans setting aside this method, took another, whereby they sought for three ratios, which added together would produce the ratio of 4 to 7, being the expression of the fourth or *diatonic*. And as this might be variously done, so they contrived various differences of *genus*.

But they did not admit all ratios indiscriminately. They chiefly regarded such as were multiple and superparticular; and did not admit of the superpartient, but through necessity, and much less of incommensurable expressions. Ptolemy gives us several divisions of the *tetrachord*, partly of his own and partly of others, which we shall here place in one short view from Dr. Wallis's Appendix to Ptolemy's Harmonics.

GENUS. By the word *genus*, in *Natural History*, we understand a certain analogy of a number of species making them agree together in the number, figure, and situation of their parts in such a manner, that they are easily distinguished from the species of any other *genus*, at least by some one article. This is the proper and determinative sense of the word *genus*, whereby it forms a subdivision of any class or order of natural beings, whether of the animal, vegetable, or mineral kingdom, all agreeing in certain common and distinctive characters. See **GENERAL NAME.**

GENUS, in *Astronomy*, is one of the common places or **TOPOGRAPHY**, and contains under it two or more sorts of things differing in nature. See **GENUS** in *Logic*. Besides, authors distinguish the use of *theory*, as also *ontology*, or *discovery*, produced thereby, into three *genus*, or kinds; *ampliative*, *delimitative*, and *judiciary*. To the *ampliative* kind belong **PANTRY**, **CELESTIAL**, **ETHICAL**, **PHYSICAL**, **PHYSICAL**, **PHYSICAL**, &c. To the *delimitative* kind belong **PERIODS**, **DIFFUSIONS**, **COMMENDATIONS**, &c. To the *judiciary* kind be-

long **DEFENSES**, and **ACCUSATIONS**. See **RHETORIC**, **QUALITY**, &c.

GEOCENTRIC, of *the earth*, and *surrounding*, in *Astronomy*, is applied to a planet, or its orbit, to denote it concentric with the earth; or, as having the earth for its centre, or the same centre with the earth.

All the planets are not *geocentric*; the moon, alone, is properly *geocentric*.

GEOMETRIC *arc* of a planet is its latitude from the earth; or the inclination of a line drawn to meet the planet and the earth, to the plane of the earth's (or true) ecliptic.

Or it is the angle which the straight line (connecting the planet and the earth) makes with a line drawn to meet a perpendicular let fall from the planet to the plane of the ecliptic. See **LATITUDE**.

Thus in *Tab. Astronom.* fig. 40. the angle $\angle T$ is the measure of the planet's *geometric* latitude, when the earth is in T ; and the angle $\angle t$ the measure of it when the earth is in t .

GEOMETRIC *place* of a planet is the place wherein it appears to us, from the earth, supposing the eye there fixed; or, it is a point in the ecliptic, to which a planet, seen from the earth, is referred.

GEOMETRIC *longitude* of a planet, is the distance measured on the ecliptic, in the order of the signs, between the *geometric* place and the first point of *Aries*.

GEOMETRIC, that part of practical geometry which teaches how to divide, or lay out, lands, or fields, between several owners.

The word is *Greek*, *γεωμετρικη*, formed of *γη*, *terra*, *earth*, and *μετρον*, *measure*, *measure*.

GEOMETRIC is also applied by some, to all the operations of geometry which are performed in the field.

This is more usually called **SURVEYING**, when employed in the measuring of lands, grounds, roads, countries, provinces, &c.

GEOMETRIC *figures*, the art of measuring surfaces and solids, not by imaginary right lines, as is done in geometry, but by sensible and visible things; as by the *body's rays*, &c.

GEODES, in *Natural History*, a genus of crustated bodies formed into large and in great part empty cases, enclosing a small quantity of earth or *semicircular* matter. See **SINUS**, *Tab. Foss.*, *Class. 2.*

Of this genus are five known species.

GEOTHECA, in *Botany*, a genus of the *diadelphica* *decussata* class: the calyx is parted into five segments, the corolla is ovate, and the nucleus compressed. Of this genus there is only one species.

GEOGRAPHICAL *mile* is a minute, or the fortieth part of a degree of a great circle. See **MILE**.

GEOGRAPHICAL *table*. See **MAP**.

GEOGRAPHY, formed of *γη*, *terra*, *earth*, and *γραφω*, *write*, *write*, *write*, the doctrine or knowledge of the earth, both as it is itself, and as to its affections; or a description of the terrestrial globe, and, particularly, of the known habitable part thereof, with all its parts.

Geography makes a branch of mathematics, of the mixed kind; because it considers the earth, and its affections as depending on quantity; and, consequently, as measurable; viz. its figure, place, magnitude, motion, celestial appearances, &c. with the several circles imagined on its surface.

Geography is distinguished from **cosmography**, as a part from the whole; this latter considering the whole visible world, both heaven and earth.

From **TOPOGRAPHY**, and **CHOROGRAPHY**, it is distinguished, as the whole from a part.

Clinton considers **geography** as either *extensive* or *intensive*; but Varenus more justly divides it into *general* and *particular*, or *universal* and *particular*.

Geography, *general*, or *universal*, is that which considers the earth in general, without any regard to particular countries, or the affections common to the whole globe; as its figure, magnitude, motion, land, sea, &c. And this may be subdivided into *absolute geography*, which respects the body of the earth itself, its parts and peculiar properties. See *relative*, which accounts for the appearances and accidents owing to celestial causes; and *comparative*, which explains those properties, that arise from comparing different parts of the earth together.

Geography, *partial*, or *particular*, is that which considers the constitution of the several particular regions, or countries; their bounds, figure, &c. with the mountains, forests, mines, waters, plants, and animals, &c. therein; as also, their climates, seasons, heat, weather, distance from the equator, &c. and their inhabitants, arts, foods, commodities, customs, language, religion, policy, cities, &c.

Special **geography** may be subdivided, with regard to the several periods of its progress, into *antient*, including a descrip-

description of the earth conformable to the knowledge which the ancients had till the decline of the Roman empire; of this kind Callistratus's Ancient Geography is an excellent summary: the geography of the *middle age*, which extended from the fall of the Roman empire to the reformation of learning, and makes *geography*, comprehending the actual description of the earth in that time. With regard to its objects and use, *geography* may be divided into several, which treat of the divisions and subdivisions which nature has made in the surface of the globe, and the complexion, language, state of its inhabitants, &c. &c. comprehending the different revolutions which any country or town has undergone; civil, or political, including the government of any country; *physical*, describing those countries and places that are mentioned in scripture and ecclesiastical history; *astronomical*, giving an account of the celestial jurisdiction established and exercised in various countries; and *physical*, which considers not only the surface of the globe, but also its invisible nature and substance. *Geography* is very ancient, at least the *physical part* thereof; for the ancient writers scarcely went beyond the description of countries.

The Chaldeans and Egyptians, who were distinguished by their skill in geometry and astronomy, were of course the first persons that paid any particular attention to *geography*; and it is said that the first map was made by order of Scythia I. who conquered Egypt.

It was a constant custom among the Romans, after they had conquered and subdued any province, to have a map, or painted representation thereof, carried in triumph, and exposed to the view of the spectators.

Historians relate, that the Roman senate, about a hundred years before Christ, sent geographers into divers parts, to make an accurate survey and measurement of the whole globe; but they scarce ever few the twentieth part thereof.

Before them, Neco, king of Egypt, ordered the Phoenicians to make a survey of the whole coast of Africa; which they accomplished in three years: Darius procured the Ethiopians, and the monarch of the Indus, to be surveyed. Thales of Miletus, Aristarchus of his disciples, who it is said have constituted the first sphere; Democritus, Eudoxus, &c. who made the use of maps common in Greece; Antipater of Miletus, who presented to Cleomenes, king of Sparta, a table of brass, on which he had depicted the known earth, with its seas and rivers; and other Greeks, styling themselves of the assistance derived from the Chaldeans and Egyptians, procured the study and enlarged the extent of this science. It appears that in the time of Socrates geographical maps were used at Athens, for this philosopher humbled the pride and boast of Alcibiades, by setting him to point out his territories in Asia in a map; and Pliny relates, that Alexander, in his expedition into Asia, took two geographers, Diogenes and Biston, to measure and describe the route; and that from their itineraries, the writers of the following ages took many particulars. Indeed, this may be observed, that whereas most other arts are successively by war, *geography* and fortification have been improved thereby.

Ptolemy the famous geographer of Marcellus flourished in the time of Alexander; and Aristotle seems to have been no less conversant with *geography* than philosophy: after Alexander, Seleucus Nicator, Theophrastus, the disciple of Aristotle, Eratosthenes, who published three books of geographical commentaries, and corrected a chart of Anaximander, Hipparchus, who corrected the observations of Eratosthenes, and thus furnished occasion for a dispute which greatly contributed to the improvement of *geography*, Apollonius of Cydon, who lived under Ptolemy Philometor, and Mesias, who, about fifty years after him, published a description of the whole world, Atticus of Ephesus, who gave a description of the earth in eleven books, often cited by Strabo and Pliny, and many others, whose names it would be tedious to enumerate, distinguished themselves by the cultivation and improvement of this science. *Geography* was transmitted, with the other arts, from Greece to Rome: Polybius, under a commission from Scipio Asiaticus, reconnoitred the coasts of Africa, Spain, and France, and measured the distances of all these places which Hannibal had visited in his march over the Pyrenees and Alps. Varro's works contain many geographical remarks: Zenodorus, Theodorus, and Polydeus were employed under the consularship of Julius Cæsar and Mark Anthony in surveying and measuring the globe. The commentaries of Cæsar are well known: Ptolemy encouraged Ptolemaeus, who made an imperfect measurement of the earth by celestial observations, in different places under the same meridian. Augustus was a distinguished patron and promoter of this science; in-

der whom Strabo published his *geography*. And the taste for the study and advancement of *geography* was greatly encouraged under Tiberius, Claudius, Vespasian, Domitian, and Adrian. Adrien of Chazax, who lived to the commencement of the first century of the Christian era; Pomponius Mela, who published a book entitled *De Sine Orbis*; Metius Pomponianus, who, having depicted the earth on a parchment, fell a sacrifice to the jealousy of Domitian, the emperor suspecting that he aimed at the empire; Hilary the naturalist, who has defined the countries known in his time in the third, fourth, fifth, and sixth books of his Natural History; Marinus the Tyrian, who corrected and enlarged the dictionaries of preceding geographers; and the emperor Antoninus, deserve particular mention. This abstract of the history of ancient geographers, notwithstanding whose successful labours, *geography* was still in a very imperfect state, brings us to a period, about the 150th year of the Christian era, in which Ptolemy of Alexandria contributed greatly to the improvement of this science, by a more ample and accurate description of the terrestrial globe than any had yet given of it. He availed himself of numerous observations and ancient charts; he corrected the mistakes and supplied many defects of others; and by reducing the distances of places on the earth to degrees and minutes, after the manner of Ptolemaeus, making use of the degrees of longitude and latitude, and fixing the situation of places by astronomical observations, he reduced *geography* into a regular system, and laid a foundation for those further discoveries and improvements, which naturally resulted from the progress, and at present advanced state of geometry, astronomy, navigation, and commerce. Many valuable geographical works appeared under Diocletian, Constantine, and Maximian, &c. Under the emperor Theodosius the provincial and itinerary chart or table, since known under the name of Peutinger, was depicted and formed; and the last work, that ought to be classed with those of the ancients, was the *Notitia Imperii*, attributed to Eucherius, who lived between the years 400 and 450 of the Christian era. The age of barbarism succeeded the fall of the Roman empire; and the arts and sciences were obliged to seek refuge and protection from the Arabians and Orientals in Asia; the principal of whom, distinguished by their attention to *geography*, were Almasum, caliph of Babylon, and Abulafia, a Syrian prince. After the revival of learning in Europe, and particularly during the two last centuries, *geography* has derived very considerable accretions from travels, voyages, and a variety of nautical and astronomical observations. For a fuller account of the history of ancient *geography*, see the preface to Berton's edition of Ptolemy's *Theatrum Geographicum Veteris*, Vol.

The art, however, must needs have been exceedingly defective, as a great part of the globe was then unknown; particularly all America, the northern parts of Europe and Asia, with the Terra Australis, and Magellanica; and as they were ignorant of the earth's being capable of being tiled round, and of the torrid zone's being habitable, &c.

The principal writings, in this art, among the ancients, are, Ptolemy's eight books; among the moderns are Johannes De Sacerdotio De Sphæra, with Clavius's Comment: Ricciolus's *Geographia* and *Hydrographia Reformata*; Weigelus's *Speculum Terre*; De Chales's *Geographia*, in his *Mundus Mathematicus*; and, above all, Varenus's *Geographia generalis*, with Jurin's additions: to which may be added, Leibniz's *Elementa Geographicæ generalis*; Sturm's *Compendium Geographicum*; Wolfius's *Geographia*, in his *Elementa Mathematicæ*, Gordon's, Salmon's and Guthrie's *Grammars*, &c.

GEOMANCY, GEOMANTIA, a kind of divination, performed by means of a number of little points, or dots, made on paper at random; and considering the various lines and figures, which those points present; and thence forming a pretended judgment of futurity, and deciding any question propoed.

The word is formed of the Greek *yo, terra, earth*; and *manja, divination*: it being the ancient custom to cast little pebbles on the ground, and thence to form their conjectures, instead of the points afterwards made use of.

Polydore Virgil defines *geomancy* a kind of divination performed by means of cleft or chunks made in the ground; and takes the Persian Magi to have been the inventors thereof.

GEOMETRICAL, something that has a relation to *geometry*. Thus we say a *geometrical method*, a *geometrical genius*, *geometrical strictness*, a *geometrical contrivance*, a *geometrical demonstration*.

Geometry itself seems to lead us into errors: after once reducing a thing to geometrical consideration, and finding that it answers pretty exactly, we pursue the view, are pleased with the certainty and agreeableness of the demonstrations, and apply the geometry farther and farther, till we often out-run nature.

Hence it is, that all machines do not succeed: that all compositions of music, wherein the concords are the most exactly observed, are not agreeable: that the most exact astronomical computations do not always suited the precise time and quantity of an eclipse, &c.

The reason is, that nature is not a mere abstract; mechanical levers and wheels are not geometrical lines and circles, as they are often supposed to be: the same for tunes is not the same in all men; nor at all times in the same man; and as to astronomy, as there is no perfect regularity in the motions of the planets; their orbits hardly seem reducible to any fixed, known figure.

The errors, therefore, we fall into in astronomy, music, mechanics, and the other sciences to which geometry is applied, do not properly arise from geometry, which is an infallible science, but from the false use, or the misapplication of it.

GEOMETRICAL CONSTRUCTION of an equation, is the contriving and drawing of lines and figures, whereby to demonstrate the equation, theorem, or canon, to be geometrically true. See **CONSTRUCTION OF EQUATIONS**.

GEOMETRICAL LINE OF CURVE, called also *algebraic line*, or *curve*, is that wherein the relations of the abscissas to the semiordinate may be expressed by an algebraic equation. See **ALGEBRAIC CURVES**.

Geometrical lines, are distinguished into classes, orders, or genera, according to the number of the dimensions of the equation that expresses the relation between the ordinates, and the abscissas: or, which amounts to the same, according to the number of points in which they may be cut by a right line.

Thus, a line of the first order will be only a right line; those of the second, or quadratic order, will be the circle, and the conic sections; and those of the third, or cubic order, will be the cubical and Newtonian parabolas, the cycloid of the ancients, &c.

But a curve of the first order (because a right line cannot be reckoned among the curves) is the same with a line of the second order; and a curve of the second order, the same with a line of the third order; and a line of an infinitesimal order is that, which a right line may cut in infinite points; as the spiral, cycloid, the quadratrix, and every line generated by the infinite revolutions of a radius.

However, it is not the equation, but the description, that makes the curve a geometrical one: the circle is a geometrical line, not because it may be expressed by an equation, but because its description is a postulate; and it is not a simplicity of the equation, but the simplicity of the description, which is to determine the choice of the lines for the construction of a problem. The equation that expresses a parabola, is more simple than that which expresses a circle; and yet the circle, by reason of its more simple construction, is admitted before it.

The circle and the conic sections, if you regard the dimensions of the equations, are of the same order; and yet the circle is not numbered with them in the construction of problems, but by reason of its simple description is depressed to a lower order, viz. that of a right line; so that it is not improper to express that by a circle, which may be expressed by a right line, but it is a fault to construct that by the conic sections, which may be constructed by a circle.

Hence, therefore, the law must be taken from the dimensions of equations, as observed in a circle, and so the distinction be taken away between plane and solid problems: or the law must be allowed not to be strictly observed in lines of superior kind; but that since, by reason of their more simple description, may be preferred to others of the same order, and be numbered with lines of inferior order.

In constructions that are equally geometrical, the most simple are always to be preferred, this law is so universal as to be without exception. But algebraic expressions add nothing to the simplicity of the constructions; the bare descriptions of the lines here are only to be considered; and these alone were considered by these geometers, who joined a circle with a right line. And as these are easy or hard, the construction becomes easy, or hard; and therefore it is, foreign to the nature of the thing, from any thing else to establish laws about constructions.

Either, therefore, with the ancients, we must exclude all lines but the circle, and perhaps the conic sections, out of geometry; or we must all according to the simplicity of the descriptions; if the trochoid were admitted

into geometry, we might, by its means, divide an angle in any given ratio: would you therefore blame those, who would make use of this line to divide an angle in the ratio of one number to another; and content, that this line was not defined by an equation, but that you must make use of such lines as are defined by equations?

No, when an angle were to be divided, for instance, into four parts, we should be obliged to bring a curve defined by an equation of above a hundred dimensions to do the business; which nobody could describe, much less understand; and should prefer this to the trochoid, which is a line well known, and described easily by the motion of a wheel, or circle: who would not see the absurdity?

Further, therefore, the trochoid is not to be admitted at all in geometry; or else, in the construction of problems, it is to be preferred to all lines of a more difficult description; and the reason is the same for other curves. Hence, the trisections of an angle by a conchoid, which Archimedes in his *Leemias*, and Pappus in his *Collectiones*, have preferred to the invention of all others in this case, must be allowed to be good; since we must either exclude all lines, besides the circle, and right line, out of geometry, or admit them according to the simplicity of their descriptions; in which case, the conchoid yields to none, except the circle. Equations are expressions of arithmetical computations, and properly have no place in geometry, except in so far as arithmetic truly geometrical (that is, lines, surfaces, solids, and proportionals) may be said to be some equal to others: multiplications, divisions, and such sort of computations, are newly received into geometry, and that apparently contrary to the first design of this science; for whoever considers the construction of problems by a right line and a circle, found by the first geometers, will easily perceive, that geometry was introduced that we might expeditiously avoid, by drawing lines, the tediousness of computation.

It should seem, therefore, that the two sciences ought not to be confounded together: the ancients so industriously distinguished them, that they never introduced arithmetical terms into geometry; and the moderns, by confounding both, have lost a great deal of that simplicity, in which the elegance of geometry principally consists. Upon the whole, that is arithmetically more simple, which is determined by more simple equations; but that is geometrically more simple, which is determined by the more simple drawing of lines: and in geometry, that ought to be reckoned best, which is geometrically most simple.

GEOMETRICAL LINE, or *plane*, called also simply *line*.

See **LOCUS**.

GEOMETRICAL METHOD. See **METHOD**.

GEOMETRICAL METHOD OF THE ANCIENTS. It is to be observed, that the ancients exhibited the higher parts of their geometry on the same principles as the elements of that science, by demonstration of the same kind; and that they seem to have been careful not to suppose any thing done, till by a previous problem they had shown how it was to be performed. Far less did they suppose any thing to be done that cannot be conceived, as a line or circle to be actually continued to infinity, or a magnitude to be diminished till it becomes infinitely less than what it was. The elements into which they resolved magnitudes were finite, and such as might be conceived to be real. Unbounded liberties have been introduced of late, by which geometry which ought to be perfectly clear, is filled with mystries. See *Mac LAURIN'S FLUXIONS*, Intr. p. 39, 40.

GEOMETRICAL NOTION. See **EVOLUTE**, and **OSCULUM**.

GEOMETRICAL PART, is a measure consisting of five feet.

See **PAGE**, and **PAOT**.

GEOMETRICAL PLAN, in *Architecture*. See **PLAN**.

GEOMETRICAL PLANE. See **PLANE**.

GEOMETRICAL PROGRESS. See **GEOMETRICAL PROGRESSION**.

GEOMETRICAL PROPORTION, called also absolutely, and simply, *proportion*, is a similitude or identity of ratios.

Thus, if A be to B, as C to D, they are in *geometrical proportion*; so 8, 4, 30, and 15, are *geometrical proportions*. See **PROPORTION**.

GEOMETRICAL SOLUTION of a problem, is when the problem is directly solved according to the first principles, and rules of geometry, and by lines that are truly geometrical.

In this sense we say, *geometrical solution* in contradistinction to a mechanical, or instrumental solution, wherein the problem is only solved by ruler and compasses.

The same term is likewise used in opposition to all ill-rect and inadequate kinds of solution, as by infinite serieses, &c.

We have an *geometrical way* of finding the quadrature of the

the circle, the duplicature of the cube, or two mean proportionals; mechanical ways and others, by infinite series, we have.

The ancient, Pappus informs us, in vain endeavored at the trisection of an angle, and the finding out of two mean proportionals by a right line and a circle. Afterwards they began to consider the properties of several other lines; as the parabola, the spiral, and the conic sections; and by some of these endeavored to solve these problems. At length, having more thoroughly examined the matter, and the conic sections being reduced into geometry, they distinguished geometrical problems into three kinds; viz.

1. *Plane ones*, which deriving their original from lines on a plane, may be regularly solved by a right line, and a circle.

2. *Solid ones*, which are solved by lines deriving their original from the construction of a solid that is of a cone.

3. *Linear ones*, to the solution of which are required lines more compounded.

According to this distinction, we are not to solve solid problems by other lines than the conic sections; especially if no other lines but right ones, a circle, and the conic sections, must be received into geometry.

But the moderns, advancing much farther, have received into geometry all lines that can be expressed by equations; and have distinguished, according to the degree of the equations, these lines into kinds; and have made it a law, not to construct a problem by a line of superior kind, that may be constructed by one of an inferior kind.

GEOMETRICAL figures. See SQUARE.

GEOMETRICAL table. See PLAIN table.

GEOMETRICALLY, *proportionally*, are quantities in continual proportion, or which proceed in the same constant ratio; as 6, 12, 24, 48, 96, 192, &c.

They are thus called, in contradistinction to equidistant quantities, which are called, though somewhat improperly, *arithmetically proportionals*.

GEOMETRY, the science, or doctrine of extension, or extended things; that is, of lines, surfaces, or solids. The word is Greek; *geometria*, formed of *geo*, or *earth*, and *metron*, *measure*; it being the necessity of measuring the earth, and the ports and places thereof, that gave the first occasion to the invention of the principles and rules of this art; which has since been extended and applied to numerous other things; inasmuch that geometry with arithmetic, is now the general foundation of all mathematics.

Heronius, lib. II. p. 109. edit. Weßelingii, Diodorus, lib. I. c. 51. or vol. I. p. 91. edit. Amst. 1766. and Strabo, lib. XIII. vol. II. p. 136. edit. Amst. 1767, ascribe the Egyptians to have been the first inventors of geometry; and the annual inundations of the Nile to have been the occasion of it; for that river bearing away all the bounds and landmarks of men's estates, and covering the whole face of the country, the people, say they, were obliged to distinguish their lands by the construction of their figure and quantity; and thus, by experience and habit, formed themselves a method, or art, which was the origin of geometry. A farther contemplation of the daughters of nature of fields thus laid down, and plotted in proportions might naturally enough lead them to the discovery of some of their excellent and wonderful properties; which speculation continually improving, the art became gradually improved, as it continues to do to this day. Josephus, however, seems to attribute the invention to the Hebrews; and others, among the ancients, make Mercury the inventor. Vol. VI. Virg. de Invent. lib. I. cap. 15.

From Egypt geometry passed into Greece, being carried thither, as some say, by Thales, whose it was much cultivated and improved by himself, Pythagoras, Anaxagoras of Clazomenae, Hippocrates of Chios, and Plato, who testified his conviction of the necessity and importance of geometry in order to the successful study of philosophy by the following inscription on the door of his academy, *non admittens nescire, sit ut ne ignarus de geometria eam hinc*. About fifty years after Plato lived Euclid, who collected together all those theorems which had been invented by his predecessors in Egypt and Greece, and digested them into fifteen books, entitled the *Elements of geometry*; and those propositions which were not satisfactorily proved, he most accurately demonstrated. The next to Euclid of those ancient writers, whose works are extant, is Apollonius Pergæus, who flourished in the time of Ptolemy Soter, about two hundred and thirty years before Christ, and about a hundred years after Euclid. The third ancient geometer, whose writings remain, is Archimedes of Syracuse, who was famous about ten years after Apollonius.

Vol. II. N^o 155.

We can only mention Euclidus of Cnidus, Archimedes of Tarentum, Philolaus, Eudoxus, Aristarchus of Samos, Dioscurides, the inventor of the *quadratrix*, Menaechmus, his brother, and the disciple of Plato, the two Archimedes, Conon, Theodorus, Menaechmus, Theonides, Hippias, and Nicomedes, the inventor of the conchoid; besides whom there are many other ancient geometers, to whom this science is indebted. The Greeks continued their attention to geometry, even after they were taken by the Romans. Whereas the Romans themselves were to little acquainted with this science, even in the most flourishing time of their republic, that they gave the name of mathematicians, as Tacitus informs us, to those who pursued the sciences of arithmetic and judicial astrology. Nor were they more disposed to embrace geometry, as we may reasonably imagine during the decline, and after the fall of the Roman empire. The case was different with the Greeks, among whom we find many excellent geometers since the commencement of the Christian era, and after the translation of the Roman empire. Pappus flourished under Marcus Aurelius; and we have extant the works of Pappus of Alexandria, who lived in the time of Theodosius; the commentary of Eutocius, the Mathematician, who lived about the year of Christ 540, on Aristotle's mathematical works; and the commentary on Euclid, by Pappus, who lived under the empire of Augustus. The consequent inundation of ignorance and barbarism was infectious to geometry as well as the other sciences; and those few who applied themselves to this science, did, were calumniated as magicians. However, in the times of European darkness, the Muslims were distinguished as the guardians and promoters of science; and from the ninth to the fourteenth century they produced many illustrious, great, great, geometers, &c.

At the revival of letters, there was formerly one European capable of combining and communicating the works of the ancient geometers; and geometry made by the progress still the time of Des Cartes, who published his *Geometry* in 1637. However, in 1657, Bonaventura Cavalieri, an Italian of the order of St. Francis, published his *Geometry of Indivisibles*; Gregory St. Vincent, in 1647, published his treatise, intitled *Quadratura Circuli & Hyperbolæ*, a work abounding with excellent theorems and demonstrations; and Pascal, about the same time, published his treatise of the cycloid. Geometry, as far as it was capable of deriving aid and improvement from the immensity of infinity, was indebted to the labors of Fermat, Barrow, Wallis, Mercator, Brouncker, J. Gregory, Hugenius, and others; to whom we may add Newton and Leibniz. Not FLOXOMUS. But Sir Isaac Newton contributed to the progress of pure geometry by his two treatises *De Quadratura Curvarum*, and *Philosophiæ Naturalis Principia Mathematica*, which are always be considered as the most extensive and successful application of geometry to physics. We cannot farther transcribing in this place the complements paid to this author by the editors of the Encyclopædia, who, considering the various monuments of the author's genius, and that he had made his principles often serve for the use of twenty-four, are tempted, may say, in substance to the words of Pope, that the figures of Newton themselves, even celestial globes, and that they contemplate him as a being occupying a kind of middle station between man and deity; or at least they cannot forbear exclaiming, *Non sumus, sed propter!* What a distance does their labor between one man and number!

The modern geometers are innumerable; and the names of Cotes, Maclaurin, Simpson, &c. will always be held in esteem and veneration by those who are devoted to the study of exact and mathematical science.

The philosophy of geometry is almost infinite. Few of us meet but may be reminded to the investigation by lines, upon which they become of geometrical consideration; it being a *metaphysical* that makes comparison, and gives the reasons of lines.

A human mind, metaphysical, and, in a word, all the sciences which render things susceptible of more and less, &c. all the profits and sciences, however, may be referred to geometry; for all speculative truths consist only in the relation of things, and in the relations between these relations, they may be all referred to lines. Consequences may be drawn from them; and their consequences, again, being rendered sensible by lines, they become permanent objects, which may be constantly exposed to a rigorous attention and examination; inasmuch as we have infinite opportunities both of collecting, to their certainty, and pursuing them farther.

The reason for instance, why we know so distinctly, and

Geometry itself seems to lead us into errors: after once reducing a thing to geometrical consideration, and finding that it answers pretty exactly, we pursue the view, are pleased with the certainty and agreeableness of the demonstrations, and apply the geometry farther and farther, till we often outrun nature.

Hence it is, that all machines do not succeed: that all computations of music, wherein the comports are the most rigidly observed, are not agreeable to that the most exact astronomical computations do not always forestall the precise (one and quantity of an eclipse, &c.)

The reason is, that nature is not a mere abstract, mechanical lever and wheels are not geometrical lines and circles, as they are often supposed to be: the tale for times is not the same in all men; nor at all times in the same man; and so in astronomy, as there is no perfect regularity in the motions of the planets; their orbits hardly seem reducible to any fixed, known figure.

The errors, therefore, we fall into in astronomy, music, mechanics, and the other sciences to which geometry is applied, do not properly arise from geometry, which is an infallible science, but from the false use, or the misapplication of it.

GEOMETRICAL construction of an equation, is the contriving and drawing of lines and figures, whereby to demonstrate the equation, theorem, or canon, to be geometrically true. See **CONSTRUCTION** of equations.

GEOMETRICAL line of error, called also *algebraic line*, or *curve*, is that wherein the relations of the abscissas to the ordinates may be expressed by an algebraic equation. See *Algebraic Curve*.

Geometrical lines, are distinguished into classes, *orders*, or *genera*, according to the number of the dimensions of the equation that expresses the relation between the ordinates, and the abscissas: or, which amounts to the same, according to the number of points in which they may be cut by a right line.

Thus, a line of the first order will be only a right line: those of the second, or quadratic order, will be the circle, and the conic sections; and those of the third, or cubic order, will be the cubical and Neilan parabolas, the cissoid of the ancients, &c.

But a curve of the first gender (because a right line cannot be reckoned among the curves) is the same with a line of the second order; and a curve of the second gender, the same with a line of the third order; and a line of an infinitesimal order is that, which a right line may cut in infinite points; as the spiral, cycloid, the quadratrix, and every line generated by the infinite revolutions of a radius.

However, it is not the equation, but the description, that makes the curve a *geometrical* one: the circle is a *geometrical* line, not because it may be expressed by an equation, but because its description is a postulate: and it is not a simplicity of the equation, but the easiness of the description, which is to determine the choice of the lines for the construction of a problem. The equation that expresses a parabola, is more simple than that which expresses a circle: and yet the circle, by reason of its more simple construction, is admitted before it.

The circle and the conic sections, if you regard the dimensions of the equations, are of the same order; and yet the circle is not numbered with them in the construction of problems; but by reason of its simple description is dejected to a lower order, viz. that of a right line; so that it is not improper to express that by a circle, which may be expressed by a right line, but it is a fault to construct that by the conic sections, which may be constructed by a circle.

Hence, therefore, the law must be taken from the dimensions of equations, as observed in a circle, and to the distinction be taken away between plane and solid problems: or the law must be allowed not to be strictly observed in lines of infinite kinds; but that some, by reason of their more simple description, may be pitched to others of the same order, and be numbered with lines of inferior order.

In constructions that are equally *geometrical*, the most simple are always to be preferred: this law is to universal as to be without exception. The algebraic expressions add nothing to the simplicity of the construction; the base descriptions of the lines here are only to be considered; and these alone were considered by those geometers, who joined a circle with a right line. And as there are easy or hard, the construction becomes easy, or hard; and therefore it is foreign to the nature of the thing, from any thing else to establish laws about constructions.

Either, therefore, with the ancients, we must exclude all lines besides the circle, and perhaps the conic sections, out of geometry; or admit all according to the simplicity of the descriptions: if the trochoid were admitted

into geometry, we might, by its means, divide an angle in any given ratio: would you therefore blame those, who would make use of this line to divide an angle in the ratio of one number to another; and contend, that this line was not defined by an equation, but that you must make use of such lines as are defined by equations?

If, when an angle were to be divided, for instance, into four parts, we should be obliged to bring a curve defined by an equation of above a hundred dimensions to do the business: which nobody could describe, much less understand; and should prefer this to the trochoid, which is a line well known, and described easily by the motion of a wheel, or circle: who would not for the absurdity?

Either, therefore, the trochoid is not to be admitted at all in geometry; or else, in the construction of problems, it is to be preferred to all lines of a more difficult description; and the reason is the same for other curves. Hence, the triflections of an angle by a conchoid, which Archimedes in his Lemmas, and Pappus in his Collections, have preferred to the invention of all others in this case, must be allowed to be good; since we must either exclude all lines, beside the circle, and right line, out of geometry; or admit them according to the simplicity of their descriptions; in which case, the conchoid yields to none, except the circle. Equations are expressions of arithmetical computation, and properly have no place in geometry, except so far as quantities truly geometrical (that is, lines, surfaces, solids, and proportions) may be said to be some equal to others: multiplications, divisions, and such sort of computations, are newly received into geometry, and that apparently contrary to the first design of this science; for whoever considers the construction of problems by a right line and a circle, found by the first geometers, will easily perceive, that geometry was instituted that we might expeditiously avoid, by drawing lines, the tediousness of computation.

It should seem, therefore, that the two sciences ought not to be confounded together: that the ancients too industriously distinguished them; that they never introduced arithmetical terms into geometry; and the moderns, by confounding them, have lost a great deal of that simplicity, in which the elegance of geometry principally consists. Upon the whole, that is arithmetically more simple, which is determined by more simple equations; but that is geometrically more simple, which is determined by the more simple drawing of lines; and in geometry, that ought to be reckoned best, which is geometrically most simple.

GEOMETRICAL lines, or plane, called also *simply lines*.

See **LOCUS**.

GEOMETRICAL medium. See **MEDIUM**.

GEOMETRICAL method of the ancients. It is to be observed, that the ancients established the higher parts of their geometry on the same principles as the elements of that science, by demonstrations of the same kind; and that they seem to have been careful not to suppose any thing done; till by a previous problem they had shown how it was to be performed. For this did they suppose any thing to be done that cannot be conceived, as a line or series to be actually continued to infinity, or a magnitude to be diminished till it becomes infinitely less than what it was. The elements into which they resolved magnitudes were finite, and such as might be conceived to be real. Unbounded liberties have been introduced of late, by which geometry which ought to be perfectly clear, is filled with mysticism. See Mac Laurin's Fluxions, lutt. p. 30. seq.

GEOMETRICAL system. See **EVOLUTE** and **OSCURUM**.

GEOMETRICAL law, is a statute consisting of five facts.

See **PAGE** and **FOOT**.

GEOMETRICAL plan, in *Architecture*. See **PLAN**.

GEOMETRICAL plane. See **PLANE**.

GEOMETRICAL proportion. See **GEOMETRICAL PROPORTION**.

GEOMETRICAL proportion, called also *absolutely*, and *simply proportion*, is a similitude or identity of ratios.

Thus, if A be to B, as C to D, they are in *geometrical* proportion: to 8, 4, 20, and 10, are *geometrical* proportions. See **PROPORTION**.

GEOMETRICAL solution of a problem, is when the problem is directly solved according to the strict principles, and rules of geometry, and by lines that are truly *geometrical*.

In this sense we say, *geometrical* solution in contradistinction to a mechanical, or instrumental solution, where the problem is only solved by ruler and compasses.

The same term is likewise used in opposition to all ill^{re} rect and inadequate kinds of solutions, as by infinite series, &c.

We have no *geometrical* way of finding the quadrature of the

the circle, the duplicature of the cube, or two mean proportionals; mechanical ways; and others, by infinite series, we have.

The ancient, Pappus informs us, in vain endeavored at the trisection of an angle, and the finding out of two mean proportionals by a right line and a circle. Afterwards they began to consider the properties of several other lines; as the parabola, the spiral, and the conic sections; and by some of these endeavored to solve those problems. At length, having more thoroughly examined the matter, and the conic sections being received into geometry, they distinguished *geometrical problems* into three kinds, *viz.*

1. *Plane ones*, which deriving their original from lines on a plane, may be regularly solved by a right line, and a circle.

2. *Solid ones*, which are solved by lines deriving their original from the construction of a solid that is of a cone.

3. *Linear ones*, to the solution of which are required lines more compounded.

According to this distinction, we are not to solve solid problems by other lines than the conic sections; especially, if no other lines but right ones, a circle, and the conic sections, shall be received into geometry.

But the moderns, advancing much farther, have received into geometry all lines that can be expressed by equations; and have distinguished, according to the dimensions of the equations, these lines into kinds; and have made it a law, not to construct a problem by a line of superior kind, that may be constructed by one of an inferior kind.

GEOMETRICAL figures. See *SURFACE*.

GEOMETRICAL table. See *PLAIN table*.

GEOMETRICALLY proportional, are quantities in continual proportion; or which proceed in the same constant ratio; as 6, 12, 24, 48, 96, 192, &c.

They are thus called, in contradistinction to *arithmetically* quantities; which are called, though somewhat improperly, *arithmetically proportional*.

GEOMETRY, the science, or doctrine of extension, or extended things; that is, of lines, surfaces, or solids.

The word is Greek, *geometria*, formed of *geo*, or *earth*; and *metron*, *measure*; it being the necessity of measuring the earth, and the parts and places thereof, that gave the first occasion to the invention of the principles and rules of this art; which has since been extended and applied to numerous other things; in which that *geometry* with arithmetic, is now the general foundation of all mathematics.

Herodotus, lib. ii. p. 109. edit. Weidagii, Diogenes, lib. i. § 81. or vol. i. p. 91. edit. Amst. 1746. and Strabo, lib. xxi. cap. i. p. 1336. edit. Amst. 1707. ascribe the Egyptian to have been the first inventors of geometry; and the annual inundations of the Nile to have been the occasion of it; for that river bearing away all the bounds and landmarks of men's estates, and covering the whole face of the country, the people, say they, were obliged to distinguish their lands by the consideration of their figure and quantity; and thus, by experience and habit, found themselves a method, or art, which was the origin of *geometry*. A further contemplation of the dimensions of figures of fields thus laid down, and pictured in proportion, might naturally enough lead them to the discovery of some of their excellent and wonderful properties; which (population continually improving, the art became gradually improved, as it continues to do to this day. Josephus, however, seems to attribute the invention to the Hebrews; and others, among the ancients, make Mesaurus the inventor. Pappus, de Invent. Res. lib. i. cap. 18.

From Egypt *geometry* passed into Greece, being carried thither, as some say, by Thales; where it was much cultivated and improved by himself, Pythagoras, Anaxagoras of Clazomenae, Hippocrates of Chios, and Eudoxus, who testified his conviction of the necessity and importance of *geometry* in order to the philosophical study of philosophy by the following inscription on the door of his academy, *non geometria sapientia, ut atque constantia geometria sine hoc.* About fifty years after Plato lived Euclid, who collected together all those theorems which had been invented by his predecessors in Egypt and Greece, and digested them into fifteen books, entitled the *Elements of geometry*; and those propositions which were not satisfactorily proved, he more accurately demonstrated. The next to Euclid of those ancient writers, whose works are extant, is Apollonius Pergenus, who flourished in the time of Ptolemy Evergetes, about two hundred and thirty years before Christ, and about a hundred years after Euclid. The third ancient geometer, whose writings remain, is Archimedes of Syracuse, who was famous about ten years after Apollonius.

Vol. II. N° 155.

We can only mention Euclidus of Cnidus, Archimedes of Tarentum, Philolaus, Eudoxus of Cnidus, Simon, Diodorus, the inventor of the quadrant, Menelaus, his brother, and the disciple of Plato, the two Archimedes, Conon, Theodorus, Nicomedes, Tautochrone, Hermotimus, and Nicomedes, the inventor of the conchoid; besides whom, there are many other ancient geometers, to whom this science is indebted. The Greeks continued their attention to *geometry*, even after they were invaded by the Romans. Whereas the Romans themselves were to little acquainted with this science, even in the most flourishing time of their republic, that they gave the name of *mathematicians*, as Tacitus informs us, to those who pursued the sciences of arithmetic and judicial astrology. Nor were they more disposed to cultivate *geometry*, as we may testifyably imagine during the decline, and after the fall of the Roman empire. The case was different with the Greeks, among whom we find many excellent geometers since the commencement of the Christian era, and also the translation of the Roman empire. Ptolemy lived under Marcus Aurelius; and we have extant the works of Pappus of Alexandria, who lived in the time of Theodosius; the commentary of Eutocius, the Meander, who lived about the year of Christ 540; the Arabians' interpretation of a circle; and the commentary of Boethius, by Pappus, who lived under the empire of Augustus. The consequent inundation of ignorance and barbarism was disadvantageous to *geometry*, as well as the other sciences; and those few who applied themselves to this science, &c. were calumniated as magicians. However, in those times of European darkness, the Arabians were distinguished as the guarding and promoting of science; and from the ninth to the fourteenth century they produced many illustrious geometers, geographers, &c. At the revival of letters, there was scarcely any European capable of translating and commenting on the works of the ancient geometers; and *geometry* was almost neglected till the time of Des Cartes, who published his *Geometry* in 1637. However, in 1653, Blaise Pascal, an inhabitant of the order of Jansenists, published his *Geometry of Indivisible Curves*; in 1659, Vincent Cavalieri, an inhabitant of the order of Jesuits, published his *Geometry of Indivisible Figures*; in 1684, published his *Geometriae*, entitled *Quadratura Circuli & Hyperbolae*, a work abounding with excellent theorems and paralogisms; and Pascal, about the same time, published his treatise of the cycloid. *Geometry*, as far as it was capable of derivation and improvement from the arithmetic of numbers, was indebted to the labors of Fermat, Barrow, Wallis, Mercator, Brunkius, J. Gregory, Hergott, and others; to whom we may add Newton and Leibniz. See *FLEXIBILITY*. But it was Newton who contributed to the progress of pure *geometry* by his two treatises *De Quadraturis Curvarum*, and *Enumeratio Linearum Terminum Infinitum* for Corollary, and still further by his incomparable and immortal work, entitled *Philosophiæ Naturalis Principia Mathematica*, which will always be considered as the most extensive and successful application of *geometry* to physics. We cannot better transcribe in this place the commendation paid to this author by the editors of the *Encyclopædia*, who, considering the various monuments of the author's genius, and that he had made his principal discoveries before the age of twenty-four, are transported, they say, to subscribe to the words of Pappus, that the physics of Newton resembles even celestial intelligences; and that they cannot further exclaiming, *ferre ferreus ingens*! what a distance does there subsist between one man and another!

The modern geometers are innumerable; and the names of Cotes, Maclaurin, Simpson, &c. will always be held in esteem and veneration by those who are devoted to the study of geometry and mathematics.

The province of *geometry* is almost infinite; few of us, least but may be a hundred to the imagination by lines, upon which they become of geometrical consideration; it being *geometry* alone that makes comparisons, and gives the relations of lines.

Arithmetic, made, machinery, &c. in a word, all the figures which render things susceptible of more and less, &c. all the profits and accounts of commerce may be referred to *geometry*; for all geometrical truths consist only in the relation of things, and in the relation between these relations, they may be all referred to lines.

Consequences may be drawn from them; and their consequences, again, being referred to lines, they become permanent objects, which may be constantly exposed to a rigorous attention and examination; and thus we have infinite opportunities both of acquiring, & displaying, and pursuing them further.

The reason for instance, why we know is distinctly, and more

Geometry itself seems to lead us into errors: after once reducing a thing to geometrical consideration, and finding that it answers pretty exactly, we pursue the view, are pleased with the certainty and agreeableness of the demonstrations, and apply the geometry farther and farther, till we often run our sails.

Hence it is, that all machines do not succeed: that all compositions of music, wherein the concords are the most highly observed, are not agreeable: that the most exact astronomical computations do not always forecast the precise time and quantity of an eclipse, &c.

The reason is, that nature is not a mere abstract mechanical power and wheels are not geometrical lines and circles, as they are often supposed to be: she talks for times is not the same in all men; nor at all times in the same man; and as to astronomy, as there is no perfect regularity in the motions of the planets; their orbits hardly form reducible to any fixed, known figure.

The crises, therefore, we fall into in astronomy, music, mechanics, and the other sciences to which geometry is applied, do not properly arise from geometry, which is an infallible science, but from the false use, or the misapplication of it.

GEOMETRICAL construction of an equation, is the contriving and drawing of lines and figures, whereby to demonstrate the equation, theorem, or canon, to be geometrically true. See **CONSTRUCTION** of equations.

GEOMETRICAL line or curve, called also *algebraic line*, or curve, is that wherein the relations of the abscissas to the ordinates may be expressed by an algebraic equation. See *ALGEBRAIC CURVES*.

Geometrical lines, are distinguished into classes, orders, or genera, according to the number of the dimensions of the equation that expresses the relation between the ordinates, and the abscissas: or, which amounts to the same, according to the number of points in which they may be cut by a right line.

Thus, a line of the first order will be only a right line: those of the second, or quadratic order, will be the circle, and the conic sections; and those of the third, or cubic order, will be the cubical and Nelian parabolas, the ellipsoid of the ancients, &c.

But a curve of the first gender (because a right line cannot be reckoned among the curves) is the same with a line of the second order; and a curve of the second gender, the same with a line of the third order; and a line of an infinitesimal order is that, which a right line may cut in infinite points; as the spiral, cycloid, the quadratrix, and every line generated by the infinite revolutions of a radius.

However, it is not the equation, but the description, that makes the curve a *geometrical one*: the circle is a *geometrical line*, not because it may be expressed by an equation, but because its description is a postulate: and it is not a simplification of the equation, but the easiness of the description, which is to determine the choice of the lines for the construction of a problem. The equation that expresses a parabola, is more simple than that which expresses a circle; and yet the circle, by reason of its most simple construction, is admitted before it.

The circle and the conic sections, if you regard the dimensions of the equations, are of the same order; and yet the circle is not numbered with them in the construction of problems; but by reason of its simple description is depressed to a lower order; viz. that of a right line; so that it is not improper to express that by a circle, which may be expressed by a right line, but it is a fault to construct that by the conic sections, which may be constructed by a circle.

Either, therefore, the law must be taken from the dimensions of equations, as observed in a circle, and so the distinction be taken away between plane and solid problems: or the law must be allowed not to be strictly observed in lines of inferior kinds; but that, however, by reason of their more facile description, may be preferred to others of the same order, and be numbered with lines of inferior orders.

In constructions that are equally *geometrical*, the most simple are always to be preferred: this law is so universal as to be without exception. But algebraic expressions add nothing to the simplicity of the construction; the mere descriptions of the lines here are only to be considered; and these alone were considered by those geometers, who joined a circle with a right line. And as these are easy or hard, the construction becomes easy, or hard; and therefore it is, foreign to the nature of the thing, times any thing else to establish laws about constructions.

Either, therefore, with the ancients, we must exclude all lines besides the circle, and perhaps the conic sections, out of geometry; or admit all according to the simplicity of the description; if the trochoid were admitted

into geometry, we might, by its means, divide an angle in any given ratio: would you therefore blame those, who would make use of this line to divide an angle in the ratio of one number to another; and contend, that this line was not defined by an equation, but that too mult make use of such lines as are defined by equations?

If, when an angle were to be divided, for instance, into 1001 parts, we should be obliged to bring a curve defined by an equation of above a hundred dimensions to do the business; which nobody could describe, much less make ready; and should prefer this to the trochoid, which is a line well known, and described easily by the motion of a wheel, or circle; who would not run for the absurdity? Either, therefore, the trochoid is not to be admitted at all in geometry; or else, in the construction of problems, it is to be preferred to all lines of a more difficult description; and the reason is the same for other curves. Hence, the triflections of an angle by a conchoid, which Archimedes in his Lemmas and Pappus in his Collections, have preferred to the invention of all others in this case, must be allowed to be good; since we must either exclude all lines, beside the circle, and right line, out of geometry, or admit them according to the simplicity of their descriptions; in which case, the conchoid yields to none, except the circle. Equations are expressions of arithmetical composition, and properly have no place in geometry, except so far as quantities truly geometrical (that is, lines, surfaces, solids, and proportions) may be tied to be some equal to others: multiplications, divisions, and such sort of computations, are newly received into geometry, and that apparently contrary to the first design of this science, for whoever considers the construction of problems by a right line and a circle, found by the first geometers, will easily perceive, that geometry was instituted that we might expeditiously avoid, by drawing lines, the tediousness of computation.

It should seem, therefore, that the two sciences ought not to be confounded together; the ancients too industriously distinguished them, that they never introduced arithmetical terms into geometry; and the moderns, by confounding both, have lost a great deal of that simplicity, in which the elegance of geometry principally consists. Upon the whole, that is arithmetically more simple, which is determined by more simple equations; but that is geometrically more simple, which is determined by the more simple drawing of lines: and in geometry, that ought to be reckoned best, which is geometrically most simple.

GEOMETRICAL line, or *plane*, called also *simply line*.

See **LOCUS**.

GEOMETRICAL medium. See **MEANUM**.

GEOMETRICAL method of the ancients. It is to be observed, that the ancients established the higher parts of their geometry on the same principles as the elements of that science, by demonstrations of the same kind; and that they seem to have been careful not to suppose any thing done, till by a previous problem they had shown how it was to be performed. For let us suppose any thing to be done that cannot be conceived, as a line or series to be actually continued to infinity, or a magnitude to be diminished till it becomes infinitely less than what it was. The elements into which they related magnitudes were finite, and such as might be conceived to be real. Unbounded liberties have been introduced of late, by which geometry which ought to be perfectly clear, is filled with mysteries. See Mac Laurin's Fluxions, letter p. 39, 40.

GEOMETRICAL system. See **EVOLUTE**, and **ORCULUM**.

GEOMETRICAL yard, is a measure consisting of five feet.

See **PAGE**, and **FOOT**.

GEOMETRICAL plan, in *Architecture*. See **PLAN**.

GEOMETRICAL place. See **PLACE**.

GEOMETRICAL progression. See **GEOMETRICAL PROGRESSION**.

GEOMETRICAL proportion, called also *absolutely*, and *simply*, *proportion*, is a similitude or identity of ratios. See **RATIO**.

Thus, if A be to B, as C to D, they are in *geometrical proportion*: so 2, 4, 30, and 15, are *geometrical proportions*. See **PROPORTION**.

GEOMETRICAL solution of a problem, is when the problem is directly solved according to the strict principles, and rules of geometry, and by lines that are truly *geometrical*.

In this sense we say, *geometrical solution* in contradistinction to a mechanical, or instrumental solution, where the problem is only solved by ruler and compasses.

The same term is likewise used in opposition to all intricate and inadequate kinds of solutions, as by infinite serieses, &c.

We have no *geometrical way* of finding the quadrature of

the

the circle, the duplicate of the cube, or two mean proportionals, mechanical ways and others, by infinite series, we have.

The ancients, Pappus informs us, in vain endeavoured at the trisection of an angle, and the finding out of two mean proportionals by a right line and a circle. After words they began to consider the properties of several other lines; as the parabola, the ellipse, and the conic sections; and by some of these endeavoured to solve those problems. At length, having more thoroughly examined the matter, and the conic sections being reduced into geometry, they distinguished geometrical problems into three kinds: viz.

1. *Plane ones*, which deriving their original from lines on a plane, may be regularly solved by a right line, and a circle.

2. *Solid ones*, which are solved by lines deriving their original from the consideration of a solid; that is, of a cone.

3. *Linear ones*, to the solution of which are required lines more compounded.

According to this distinction, we are not to solve solid problems by other lines than the conic sections; especially if no other lines but right ones, a circle, and the conic sections, must be received into geometry.

But the moderns, advancing much farther, have reduced into geometry all lines that can be expressed by equations; and have distinguished, according to the dimensions of the equations, those lines into kinds, and have made it a law, not to construct a problem by a line of higher kind, than may be constructed by one of an inferior kind.

GEOGRAPHICAL SPHERE. See SPHERE.

GEOMETRICAL TABLE. See PEARL TABLE.

GEOMETRICALLY PROPORTIONAL, are quantities in continual proportion, or which proceed in the same constant ratio; as by 12, 24, 48, 96, 192, &c.

They are thus called, in contradistinction to equidistant quantities; which are called, though somewhat improperly, *ARITHMETICALLY PROPORTIONAL*.

GEOMETRY, the science, or doctrine of extending, or extended things; that is, of lines, surfaces, or solids.

The word is Greek, *γεωμετρικη*, formed of *γη*, or *γῆ*, earth; and *μετρον*, measure; it being the necessity of measuring the earth, and the parts and places thereof, that gave the first occasion to the invention of the principles and rules of this art; which has since been extended and applied to numerous other things; inasmuch that *geometry* with *arithmetic*, is now the general foundation of all mathematics.

Herodotus, lib. ii. p. 102. edit. Weilingii, Diodorus, lib. i. p. 31. or vol. i. p. 91. edit. Amst. 1746. and Strabo, lib. xiv. vol. ii. p. 116. edit. Amst. 1757, ascribe the Egyptian to have been the first inventors of *geometry*; and the annual inundations of the Nile to have been the occasion of it; for that river bearing away all the loam and husks of men's clay, and covering the whole face of the country, the people, say they, were obliged to distinguish their lands by the configuration of their *figure*, and quantity; and thus, by experience and trial, learned themselves a method of art, which was the origin of *geometry*. A farther contemplation of the draughts of figures of fields thus laid down, and plotted in proportion, might naturally enough lead them to the discovery of some of their excellent and wonderful properties; which speculation continually improving, the art became gradually improved, as it continues to do to this day. Josephus, however, seems to attribute the invention to the Hebrews; and others, among the ancients, make Mercury the inventor. Ptolemy, de Isidoro. lib. i. cap. 18.

From Egypt *geometry* passed into Greece, being carried thither, as some say, by Thales; whose it was much cultivated and improved by himself, Pythagoras, Anaxagoras of Clazomenae, Hippocrates of Chios, and Plato, who testified his conviction of the necessity and importance of *geometry* in order to the successful study of philosophy by the following inscription on the door of his academy, *quis inquit non sciens, let at the entrance of geometry enter here*. About fifty years after Plato lived Euclid, who collected together all those theorems which had been invented by his predecessors in Egypt and Greece, and digested them into fifteen books, entitled the *ELEMENTS of geometry*; and those propositions which were not satisfactorily proved, he more accurately demonstrated. The next to Euclid of those ancient writers, whose works are extant, is Apollonius Pergæus, who flourished in the time of Ptolemy Epiphanes, about two hundred and thirty years before Christ, and about a hundred years after Euclid. The third ancient geometer, whose writings remain, is Archimedes of Syracuse, who was famous about ten years after Apollonius.

Vol. II. N° 150.

We can only mention Eudoxus of Cnidus, Archimedes of Tarentum, Philolaus, Euclidides, Antisthenes of Samos, Dinocrates, the inventor of the *spiral*, Eratosthenes, Menecmus, his brother, and the disciple of Plato, the two Archimedes, Conon, Trismeleus, Nicomedes, Leon, Theodorus, Hermotimus, and Nicomedes, the inventor of the *conchoid*; besides whom, there are many other ancient geometers, to whom this science is indebted. The Greeks commanded their attention to *geometry*, even after they were subdued by the Romans. Whereas the Romans themselves were to little acquainted with this science, even in the most flourishing time of their republic, that they gave the name of *mathematicians*, as Tacitus informs us, to those who pursued the chimera of divination and judicial astrology. Nor were they more disposed to cultivate *geometry*, as we may reasonably imagine during the decline, and after the fall of the Roman empire. The case was different with the Greeks, among whom we find many excellent geometers since the commencement of the Christian era, and after the translation of the Roman empire. Bodinus found under Marcus Aurelius, and we have extant the works of Pappus of Alexandria, who lived in the time of Diocletian, the comestary of Eutocius, the Academic, who lived about the year of Christ 440, an Aristotelian's commentary of a circle, and the comestary on Euclid, by Pappus, who lived under the empire of Anastasius.

The consequent foundation of ignorance and barbarism was unfavourable to *geometry*, as well as the other sciences; and those few who applied themselves to this science, &c. were celebrated as *magicians*. However, in the times of European darkness, the Muslims were distinguished as the guardians and promoters of science; and from the ninth to the fourteenth century they produced many astronomers, geometers, geographers, &c. At the revival of letters, there was scarcely one European capable of translating and commenting on the works of the ancient geometers; and *geometry* made but the progress till the time of Des Cartes, who published his *Geometry* in 1637. However, in 1657, Bonaventura Cavalieri, an Italian of the order of Jesuits, published his *Geometry of Indivisible Geometry*; in 1659, in 1667, published his treatise, intitled *Quadratura Circuli & Hyperbolæ*, a work abounding with excellent theorems and paradoxes; and Pascal, about the same time, published his treatise of the cycloid. *Geometry*, as far as it was capable of deriving aid and improvement from the arithmetic of numbers, was indebted to the labours of Fermat, Barrow, Wallis, Mercator, Brouncker, Gregory, Huygens, and others; to whom we may add Newton and Leibnitz. See FLOXUS.

But to have Newton contributed to the progress of pure *geometry* by his two treatises *De Quadratura Curvarum*, and *Enumeratio Linearum Tertio Ordinis*; by Cotesius, and still further by his incomparable and immortal work, intitled *Philosophiæ Naturalis Principia Mathematica*, which will always be considered as the most extensive and successful application of *geometry* to physics. We cannot finish this article in this place, the consideration just to this author by the editors of the *Encyclopædia*, who, considering the various monuments of the author's genius, and that he had made his principal discoveries before the age of twenty-four, are tempted, not far to subscribe to the words of Pope, that the faculty of Newton surpasses even celestial intelligences; and that they contemplate him as a being exceeding a kind of middle station between man and deity; or at least they cannot forbear exclaiming, *non hominem præstat*; what a distance does there stand between our man and another!

The modern *geometry* is innumerable; and the names of Cotes, Maclaurin, Simpson, &c. will always be held in esteem and veneration by those who are devoted to the study of *geometry* and mathematics.

The province of *geometry* is almost infinite; few of our best but may be represented to the imagination by lines, upon which they become of *geometrical* consideration; it being *geometry* alone that makes comparisons, and finds the relations of lines.

Astronomy, music, mechanics, and, in a word, all the sciences which render things susceptible of more and less, i. e. all the precise and accurate sciences may be reduced to *geometry*; for all speculative truths consisting only in the relation of things, and in the relations between whole relations, they may be all referred to lines. Consequently may be drawn from them, and their consequences, again, being rendered sensible by lines, may become permanent objects, which may be constantly exposed to a rigorous attention and examination; so that we have infinite opportunities both of acquiring, and their certainty, and pursuing their further.

The reason for instance, why we know so distinctly, and

mark to precisely, the concords called *stave, fifth, fourth*, &c. is that we have learnt to express sounds by lines, i. e. by chords accurately divided; and that we know, that the chord, which sounds *clavier*, is double of that with which it makes *clavier*; that the *fifth* is the sesquialterate ratio, or as three or two; and so of the rest. The ear itself cannot judge of sounds with such a nice precision; its judgments are too faint, vague, and variable, to form a science. The finest bell tuned ear cannot distinguish many of the differences of sounds; whence many musicians deny any such differences; as making their sense their judge. Some, for instance, admit no difference between an octave and three ditones; and others, none between the greater and lesser tone; the comma, which is the real difference, is infensible to them; and much more the *seismo*, which is only half the comma.

It is only by reason, then, that we learn, that the length of the chord which makes the difference between certain sounds, being divisible into several parts, there may be a great number of different sounds contained therein, useful in music, which yet the ear cannot distinguish. Whence it follows, that had it not been for arithmetic and *geometry*, we had had no such thing as regular fixed music; and that we could only have succeeded in that art by good luck, or force of imagination; i. e. music would not have been any science founded on incontestable demonstrations: though we allow, that the tunes composed by force of genius and imagination, are usually more agreeable to the ear, than those composed by rule. So, in mechanics, the heaviness of a weight, and the distance of the centre of that weight from the fulcrum, or point it is sustained by, being inseparable of plus and minus, they may both be expressed by lines: whence *geometry* becomes applicable thereto; in virtue whereof infinite discoveries have been made, of the utmost use in life.

Geometrical lines and figures are not only proper to represent to the imagination the relations between magnitudes or between things susceptible of more and less; as spaces, times, weights, motions, &c. but they may even represent things which the mind can no otherwise conceive, e. g. the relations of incommensurable magnitudes.

It must be observed, that this use of *geometry* among the ancients was not strictly scientific, as among us; but rather symbolical: they did not argue, or deduce things and properties unknown from lines; but represented or delineated by them things that were known. In effect, they were not used as means or instruments of discovering, but as images or characters, to preserve, or communicate, the discoveries that were already made.

The Egyptians, Gale observes, used *geometrical* figures, not only to express the generations, mutations, and destructions of bodies; but the manner, attributes, &c. of the spirit of the universe, who, diffusing himself from the centre of his unity, through infinite concentric circles, pervades all bodies, and fills all space. But of all other figures they most affected the circle, and triangle; the first, as being the most perfect, simple, capacious, &c. of all figures; whence Hermetes borrowed it to represent the divine nature; describing God to be an intellectual circle or sphere, whose centre is every where, and circumference no where. See Kirch. *Optic. Egyptiac.* and Gale Phil. General. lib. ii. cap. 2.

The ancient *geometry* was confined to very narrow bounds, in comparison of the modern. It only extended to right lines and curves of the first order, or conic sections; whereas into the modern *geometry* new lines of infinitely more and higher orders are introduced.

Geometry is commonly divided into four parts, or branches; *PLANIMETRY*, *ALTIMETRY*, *LONGIMETRY*, and *STEREOMETRY*.

Geometry, again, is distinguished into *theoretical* or *speculative*, and *practical*.

The first contemplates the properties of continuity, and demonstrates the truth of general propositions, called *THEOREMS*.

The second applies those speculations and theorems to particular uses in the solution of PROBLEMS.

GEOMETRY, SPECULATIVE, again may be distinguished into *elementary* and *higher*.

GEOMETRY, elementary or common, is that employed in the consideration of right lines, and plain surfaces, and solids generated therefrom.

GEOMETRY, higher or sublime, is that employed in the consideration of curve lines, conic sections, and bodies formed therefrom.

The writers who have cultivated and improved *geometry* may be distinguished into elementary, practical, and those of the sublime *geometry*.

The principal writers of elements, see enumerated under ELEMENTS.

Those of the higher *geometry* are Archimedes, in his books *De Sphaera*, *Cylindro*, and *Circuli Dimensionibus*; as also *De Spirali*, *Conoidibus*, *Sphaeroidibus*, *De Quadratura Parabola*, and *Arenario*; Kepler, in his *Stereometria Nova*; Catalanis, in his *Geometria Galvianorum*; and Tartagliola, *De Solidis Sphaericis*; Pappus Alexandrinus, in *Collectionibus Mathematicis*; Paulus Guldinus, in his *Mechanica* and *Statica*; Barrow, in his *Lectiones Geometricae*; Huygens, *De Circuli Magnitudine*; Bullialdus, *De Lineis Spiralibus*; Schoten, in his *Exercitationes Mathematicae*; De Billy, *De Proportionibus Harmonicis*; Lalouere, *De Cycloide*; Ferri, *Ernest. Com. ab Hardenstein, in Dialectica Circularum*; Viviani, in *Exercit. Mathematicae de Formatione & Mensura Formarum*; Bep. Palma, in *Geomet. Exercitation. and Apoll. Pergensis, De Sectione Rationis*.

For practical *geometry*, the fullest and completely treatises are those of Mallet, written in French, but without the demonstrations; and those of Schweener and Cantelani, both in High Dutch. In this class are likewise to be ranked Clavius, Tacquetus, and Ozanam's *Practical Geometries*; De la Hire's *École des Apprentis*; Reinholdus's *Geodesia*; Hartman Beyer's *Stereometria*; Vogler's *Geometria Subterranea*; all in High Dutch; Hülfs, Gellert, Guldmanus, Scheffele, and Ozanam, on the Section, &c.

GEOMETRY, characteris } See CHARACTER.
GEOMETRY, physical } See PHYSICAL.

GEOMORPH, *topography*, in *Antiquity*, the division or class of the ancient Athenians, employed in agriculture.

GEOPONIC, something describing or relating to AGRICULTURE. Cato, Varro, Coscomella, Palladius, and Pliny, are sometimes called *geponic* writers.

GEORGE, St. a name whereby several orders, both military and religious, are denominated. It took its rise from a saint famous throughout all the East, called by the Greeks *Μεγαλειότης*, i. e. great *martyr*.

On some medals of the emperors John and Manuel Comneni, we have the figure of St. George armed, holding a sword or javelin in one hand, and in the other a buckler, with this inscription; an O, and therein a little

α, and Ε-ΠΙΟC, making Ο ΑΓΙΟΣ ΓΕΩΡΓΙΟΣ, O

Holy George. He is generally represented on horseback, as being supposed to have frequently engaged in combats in that manner.

He is highly venerated throughout Armenia, Moscovy, and all the countries which adhere to the Greek rite; from the Greek, his worship has long ago been received into the Latin church; and England and Portugal have both chosen him for their patron saint.

GEORGE, St. is particularly used for an English order of knights, more commonly now called the *order of the Garter*. See GARTER.

GEORGE, knight of St. There have been various orders under this denomination, most of which are now extinct; particularly one founded by the emperor Frederic III. in the year 1476, to guard the frontiers of Bohemia and Hungary against the Turks; another, called St. George of Alfama, founded by the kings of Arragon; another in Austria and Carinthia; and another in the republic of Genoa, still subsisting, &c.

GEORGE, religious of the order of St. Of these there are divers orders and congregations; particularly a canon regular of St. George in Alga, at Venice, established by authority of pope Boniface IX. in the year 1404. The foundation of this order was laid by Bartholomew Colonna, who preached, in 1360, at Padua, and some other villages in the state of Venice. Pope Pius V. in 1570, gave these canons precedence of all other religious. Another congregation of the same institute in Sicily, &c.

St. GEORGE's cross. See CROSS.

GEORGEABLE, a piece of gold, current at six shillings and eight pence in the reign of king Henry VIII.

GEORGIAN monks and nuns are religious of Georgia, in Asia, who follow the rule of St. Basil.

GEORGIC, something that relates to the culture or tillage of the ground.

The word is borrowed from the Latin *georgicus*, and that of the Greek *γεωργικός*, of *γεω*, terra, earth; and *ργος*, opus, labor, of *ργον*, opus, work.

The *Georgics* of Virgil are four books composed by that poet on the subject of agriculture.

GEOSCOPY, a kind of knowledge of the nature and qualities of the ground or soil, gained by viewing and considering it.

The word is formed of the Greek *γῆ*, earth, and *σκοπεῖν*, I see, view.

Geratopy is only conjectural; but its conjectures are very well grounded.

GEOSTATICS. See STATICS.

GERANITES, of *geranos*, a crane, in *Natural History*, a name given by some authors to such pieces of AGATE, or any other of the semi-pellucid gems, as have round spots in them, resembling in colour the eye of a crane.

GERANIUM, *crani bell*, in *Botany*, a genus of the *monadelphia divaricata* class. Its characters are these: the flower hath a permanent empalement, composed of five small oval leaves, and five oval or heart-shaped petals, spreading open, which are in some species equal, and in others the upper two are much larger than the three lower. It has ten stamens, alternately longer than each other, but shorter than the petals, and terminated by oblong tumours. In the bottom of the flower is situated a five-angled germ, which is permanent. The flower is succeeded by five seeds, each being wrapped up in the hulk of the book, where they are twisted together at the point, so as to form the resemblance of a hawk's beak. Linnaeus enumerates thirty, and Miller forty-three species.

The common wild sorts of this plant, and these also which are brought to the curious from the colder climates, are hardy enough, and require little care; but the African species, and the others from hot countries, which make very beautiful a figure in our green-houses, require great care in their culture and propagation.

These may be propagated by seed, which should be sown toward the end of March in beds of light earth, and carefully shading them from the sun, and giving them frequent but gentle waterings, till they are well rooted. The mats with which these beds are covered are to be taken off in gentle showers, and always in the hot weather at night, that the plants may have the benefit of the dew. They should remain about two months in this bed, by which time they will have taken root. Some pots of about seven inches wide are to be filled with light earth, and the plants are to be carefully taken up with as much as possible of their own earth about them, and planted severally in the middle of these pots; when they are to be set in a shady place, and watered at times till they have taken root. When they are well-rooted, they should be set in a more exposed place to harden them, and should stand out till the middle of October; but when the mornings begin to become frosty, they must be removed into the green-house, and then placed as near the windows as possible, and the windows should be opened upon them till the weather is very cold. During the winter, they must be frequently watered a little at a time, and their dead leaves should be pulled off. They must not stand under the shade of other plants, nor need any artificial heat.

Those who are desirous that their plants should be large and flower soon, sow the seeds on a moderate hot-bed in the spring, when they are come up, they should not be drawn weak, and the pots into which they are transplanted should be plunged into another moderate hot-bed, shading them from the sun, till they have taken root, and gradually insuring them to the open air, into which they should be removed in the beginning of June, and placed in a sheltered situation with other exotic plants.

The shrubby African *geraniums* are commonly propagated by cuttings, which, planted in a shady border, in June or July, will take good root in five or six weeks; and they may then be taken up and planted in separate pots, placing them in the shade till they have taken new root; after which they may be removed into a sheltered situation, and treated as the seedling plants.

Geranium stands recommended as one of the greatest volubilities and adherents of the vegetable world, and is highly extolled for its power of stopping profusions of the menfes, and hemorrhages of all kinds. Experience confirms the truth of this, especially among the poor people in the country, and it were to be wished that the plant could be brought into more esteem in the shops, where at present it is disregarded.

GERANOS, *Fraxin*, in *Antiquity*, a remarkable dance performed in the festival called *DELIA*.

GERARDIA, in *Botany*, the name of a genus of plants of the *didynamia angustifolia* class, the characters of which are these: the perianthium is composed of one leaf divided into five segments, and remains after the flower is fallen: the flower is of the labiate kind, and composed only of one leaf: the tube is longer than the cup, and of a cylindric figure: the upper lip is erect, plain, broad, oblate, and emarginated: the lower lip is bent backwards, and divided into three segments: the two side ones are long and emarginated, and the middle one shorter and blunt. The stamens are four filaments, somewhat shorter than the flower, and two of these are a little shorter than the other two. The stamens

are small. The pistil of this plant is small and oval. The style is simple and short, and the stigma is obtuse. The fruit is an oval bivalve capsule, containing two cells, and opening at the bottom when ripe: the seeds are single and oval. There are six species.

GERBERA, in *Botany*. See *AMERICA*.

GERE SOL, in *Metaphysics*, one of the *CLERES*.

GERFALCON, or *GERALCON*. See *FALCON*. This is naturally a very bold, wild and fierce bird, and is therefore very difficult to be reclaimed; but when that is done, it proves one of the very best kinds, and will fly at almost any thing. The beak of the *gerfalcon* is always blue, and the claws are remarkably long and strong.

In going up to the gate, the sportsman expresses it, these birds do not hold the same sort of course that others do, but immediately climb up upon the train on light of the bird, and as soon as they have reached her, they immediately make the attack, and generally pull her down at the first encounter; but if not, always at the second or third.

This sort of hawk is to be fed and rewarded like the others. It is of a very dry and crumbly nature, and is so foolish, that it loves to keep the calling a long time: therefore, instead of cotton, it is proper to give them sometimes a calling of tow, and to keep them sharp till As to the reclaiming this sort of hawk, it is only to be done by gentleness and kindness; and when the has been taught to be tamed loose, she is next to be learned to come to the pelt of hens or other fowl. But she must never be suffered to take any living fowl, for that will be apt to draw away her love from the hand and voice. Whenever she sees the falconer must be close to her, and must make her eat the choicest pieces out of his hand. There is great care to be taken in the making these birds, for as they are made at first, so they are for ever; and it is a necessary caution, with birds of this bold and fierce nature, not to hurry over the business, but to repeat the same thing very often till it is perfectly fixed. See *HAWK*.

GERM. See *GERMIN*.

GERMAN, in matters of *Gerontology*, signifies whole, entire, or own.

Germani, *quasi unum sint*, genus. Full. Hence,

GAEMAN, brother, denotes a brother both by the father's and mother's side, in contradistinction to uterine brothers, &c. who are only so by the mother's side.

GERMAN, *emile*, are those in the first or second degree, being the children of brothers or sisters.

Among the Romans we have no instance of marriage between consins *german* before the time of the emperress Claudius, when they were very frequent.

Theodosius prohibited them under very severe penalties, even fine and prostration. See *CONFRATERNITY*.

GERMAN *accus*, *brevis*, *hills*, *black*, *corn*, *compotes*, *empire*, *flour*, *language*, *major*, *manus*. See the several substantives.

GERMANDER, *reserium*, in *Botany*, a genus of the *didynamia angustifolia* class. Its characters are these: the empalement of the flower is of one leaf, cut into five acute equal segments at the top, and is permanent: the flower is of the lip kind, with one petal, having a short cylindrical tube, a little incurved at the chap; the upper lip is erect, and deeply cut into two acute segments; the lower lip spreads, and is cut into three; the middle one is large and roundish, the two side ones acute and erect; it hath four awl-shaped stamens, which are longer than the upper lip, and are prominent between the segments, terminated by small summits. It has a germen divided in four parts, supporting a slender style, crowned by two slender stigmas; the germen afterwards turns to four roundish naked seeds, which ripen in the empalement. Miller enumerates nineteen, and Linnaeus thirty-five species.

The smaller creeping *germander*, or *shamduy*, *minor reserium*, having oval leaves with crenated cuts, foot-stalks, and flowers growing almost in whorls, grows wild in the south of France and Germany; but with us it is raised in gardens, and flowers in June and July. The leaves and tops have been recommended as diuretic and diaphoretic. These are an ingredient in many of the compositions of the shops, and are given in infusion in fevers, in suppressions of urine, in the scarry, the gout, and jaundice; and where the use of it is continued sufficiently, generally with success. The tops, gathered when the seeds are formed, are generally preferred to the leaves. Their dose, in substance, is from half a dram to a dram, or more. They give out their virtues both to watery and spirituous menstria.

The water *germander*, or *germander*, having oblong saw-indented leaves, sitting close to the branches, and flowers growing by pairs at the wings of the stalk which is distended, grows naturally in the ile of Ely, and other fenny parts of England, is perennial, and flowers in July. The whole plant has an odour like that of garlic. The leaves,

the vehemence and energy of the expression, as the natural and genuine effect of it. *Geyare* is either natural, or from *imitation*. The former denotes such actions and motions, either of the whole body, or of some particular part of it, as naturally accompany our words, just as these result from the impressions of our minds. As to the whole body, it should not continue long in the same position, but be constantly changing, with a gentle and moderate motion. As to the several parts of the body, the head is the most considerable: to lift it up too high, has the air of arrogance and pride; to stretch it out too far or throw it back, appears clownish and unmanly; to hang it downwards on the breast, shows an unmanly bashfulness and want of spirit; and to suffer it to lean on either shoulder, argues both indolence in calm and feasted discourses, the head should keep its natural state and upright posture, occasionally moving, and turning gently sometimes on one side, and sometimes on the other, as occasion requires, and then returning back to its natural position. It should always accompany the other actions of the body, except in aversion, which is expressed by stretching out the right hand, and turning the head to the left. But nothing is more indecent than violent motions and agitations of the head.

The passions are principally represented by the countenance, and the several parts of the face contribute to the proper and decent *geyare* of the whole. In a calm and easy discourse, all the features retain their natural situation. In *forrow*, the forehead and eye-brows lower, and the cheeks hang down; but in expressions of joy and cheerfulness, the forehead and eye-brows are expanded, the cheeks contracted, and the corners of the mouth drawn upwards. Anger and resentment contract the forehead, draw the brows together, and thrust out the lips and teeth, elevates both the brows and forehead. To these natural signs of the passions the orator should endeavour to conform.

The motions of the eyes require the most careful management; because, as Cicero observes, other parts of the countenance have but few motions; whereas all the passions of the soul are expressed in the eyes by many different actions, that cannot possibly be represented by any *geyare* of the body, if the eyes be kept in a fixed posture. De Orat. lib. iii. cap. 59. Thus, in speaking on pleasant and delightful subjects, the eyes are brisk and cheerful; but they sink and are languid in delivering any thing melancholy and sorrowful. In anger, the eyes discover a certain vehemence and intemperance; in expressions of hatred and desecration, the eyes are turned either aside or downwards: thus Virgil has expressed Dido's resentment and disdain of Aeneas.

Ille fide fures oculis averfa torquet. Aen. lib. vi. ver. 459.

The eyes are also sometimes turned downwards, to express modesty; and they should be always turned towards the object which is addressed. A gentle and moderate motion of the eyes is commonly most suitable, whereby they may be directed to some of the audience with an air of respect and modesty; but their motions ought to vary, according to the different nature of the passions which they are designed to discover in the speaker, and convey to his hearers.

The shoulders should neither be elevated nor depressed: a continued motion of the arms should be avoided; their action should be very moderate, and follow that of the hands, which need never be idle. Quintilian lays great stress on the action of the hands, when he says, "The hands, without which all *geyare* is lame and weak, have a greater variety of motions than can well be expressed; for they are almost equal to our words. Do we not desire with them, promise, call, dismiss, illustrate, beseech, detect, fear, enquire, deny? Do not they express joy, sorrow, doubt, confession, penitence, measure, plenty, number, and time? Do not they excite, restrain, prove, admit, and flatter? that in to great a variety of speech among all nations and countries, this seems to me the common language of mankind." Inst. Orat. lib. xi. cap. 3.

As all bodily motion is either upward or downward, to the right or left, forward or backward, or circular, the hands are employed by the orator in all these, except the last; and as they should correspond with our expressions, they ought to begin and end with them. In admiration, and address to heaven, they must be elevated, but never raised above the eyes; and in speaking of things below us, they are directed downwards. Side motions should generally begin from the left, and terminate gently on the right: in demonstrating, addresting, and on several other occasions, they are moved forward; and in threatening, sometimes thrown back: when the orator speaks of himself, his right hand should be gently laid on his breast. When no other motion is necessary,

the hands should be kept about as high as the breast, so as to make nearly a right angle with the arm. They should never be suffered to hang down, nor to fall upon the cushion or bar. The left-hand should never move alone, but accommodate itself to the motions of the right: in motions to the left, the right-hand should not be carried beyond the left shoulder: in promises and expressions of compliment, the motion of the hands should be gentle and slow; but in exhortation and applause, more swift. The hands should be generally open; but in expressions of compunction and *improvement*, they may be closed. Neither the breast nor the belly should be thrust out; the trunk should be easy and flexible, following itself to the motions of the head and hands; and the feet should be kept steady.

There are other *geyare*, which arise from *imitation*; as when the orator describes some action, or personates another speaking: but here he should be careful not to overact his part, by running into any ludicrous or theatrical mimicry, or changing his action or voice in a manner unsuitable to his own character. See further on this subject, Ward's Oratory, vol. ii. p. 344. &c. p. 369. &c. Scherriani's Lect. on Elocution, lect. viii. p. 113. See also ACTION, IMITATION, PRONUNCIATION, and VOICE.

GESTUS *terre*, in *Law*. See GOOD *showing*.

GETHYLLIS, in *Botany*, the name of a genus of plants of the *didymandra monogyna* class; the characters of which are these: the cup is a spatula of the lanceolated form, composed of one membranaceous indurated leaf, and containing only one flower; the flower consists of one petal; its tube is extremely slender and long; the limb is plain, and is divided into six equal segments of lanceolated form, which are of about a third part of the length of the tube; the filamina are either twelve or eighteen setaceous filaments standing in the cup; they are short and erect, and the anthers are oblong: the germs of the pistil is oblong, and stands low in the spatula under the base of the flower; the style is capillary, and of the length of the filamina, and the stigma is trifid and obtuse: the fruit is an oblong, inflated, triangular capsule, containing three cells, in which are numerous seeds. There is one species.

GEUM, in *Botany*, *Arvens*, or *Herb. Bonini*. See HERB. BONINI.

GEZIRA *cubens*, in the *Astoria Medica* of the ancients, a name given to tarsi, by Avicenna, Serapion, and others. These authors do not give any explanation of what sort of substance they mean by this name, but seem to suppose it a thing universally known, and only give a list of its qualities.

GHALGHULUWA, in *Zoology*, the Ceylonese name of a species of East Indian serpent, a snake of a pale brown, variegated with transverse streaks of white, and found among rocks and flobes.

GHAN, is a name given in Muscovy to CARAVANFRAS.

GHEMARA. See GEMARA.

GHIERKINS. See GUBERKINS.

GIAGH, or JAGHON, a cycle of twelve years, in use among the Turks and Cathayans.

Each year of the *giagh* bears the name of some animal: the first, that of a mouse; the second that of a bullock; the third, of a lynx or leopard; the fourth, of a hare; the fifth, of a crocodile; the sixth, of a serpent; the seventh, of a horse; the eighth, of a sheep; the ninth, of a monkey; the tenth, of a hen; the eleventh, of a dog; and the twelfth, of a hog.

They also divide the day into twelve parts, which they call *giaghi*, and distinguish them by the names of the same animals. Each *giagh* contains two of our hours, and is divided into eight *sebs*, as many as there are quarters of hours in our day.

GIALLOLINO, in *Natural History*, a species of yellow ochre used in painting, and called in the colour-terms, Naples yellow. It is used both as an oil and a water-colour, and likewise in enamelling and caustic painting, and the colouring of china-ware. Dr. Hill. Hist. of Foss. p. 56. considers it as a kind of solar calx, impregnated with a ferruginous calx, and describes it as a very beautiful earth, of a bright and elegant yellow, between a gold and saffron colour, and of a very loose, spongy, porous, and flinty texture. It is remarkably heavy, of a dusty surface, and gritty to the touch; it breaks easily between the fingers, and stains the hands. It adheres but slightly to the tongue, and makes a very brisk fermentation with aqua fortis. It is found in some parts of Italy, particularly about Naples, whence it is said to have its common name. It sometimes, says Dr. Hill, lies on the surface of the earth, and in other places is dug at great depths. Others have supposed that it is one of the numerous heteroclit productions of the fire in Mount Vesuvius. But Mr. Pongracz has lately demonstrated, that it is produced by art, the person who pro-

puta it at Naples, scrupulously conceals every circumstance that might lead to a discovery of its nature and preparation, which are known only to himself. M. Pongouet has, however, found that it contains an abundant earth, a vegetable acid, united with lead, an aluminous and ammoniacal salt, and a calx of antimony. Accordingly, on mixing together intimately twelve ounces of ceruss or white lead, one of alum, one of sal ammoniac, and three ounces of diaphanous antimony, in an unglazed earthen pan covered over, and expelling the mixture to the heat of a moderate fire, during the space of seven or eight hours, he obtained a substance of the same colour with the *giallo*, and possessing all its properties; as he has been assured by the most able painters who have used it, and have found no difference between it and the true Naples yellow. *Hist. Acad. Sciences*, 1765.

GIANT, *gigante*, a man of extraordinary, enormous stature and bulk.

The reality of giants, and of nations of giants, is much controverted among the learned. Travellers, historians, and relations, both sacred and profane, furnish various instances thereof; a great part of which naturalists and antiquaries set aside.

Those among the ancients who speak of giants, as hills-triangles, and affirm there were such things, are *Cicero*, *De Bellis Gallicis*, lib. 1. *Tacitus*, *De Moribus Germanorum*, and *Aulus*, lib. 1. *Strabo*, lib. 10. c. 3. *St. Augustine*, *De Civit. Dei*, lib. 10. c. 1. and *Santo-Gratiano*, at the end of his preface, among the moderns, *Hieron*, *Macrobius*, *Isidorus*, *de Gigantibus*, *Chalcidius*, *De Gigantibus*, *Kluster*, *Mund. Generation*, lib. 10. sect. 10. c. 4. and to many others, that Stephenus in his notes on *Santo-Gratiano's* assertion, nothing can be more extravagant than to deny or allegorize the authorities we have concerning them.

Dr. Derham observes, that though we read of giants before the flood, *Gen. vi. 4.* and more plainly after it, *Numb. xiii. 33.* yet it is highly probable the size of man has always been the same from the creation; for as to the *Nephilim*, *Gen. vi.* the ancients vary about them, some taking them for monsters of impiety, others for rapine, tyranny; as to those, *Numb. xiii.* which were evidently spoken of as men of a gigantic size, it is probable the fears of the spies might add thereto.

Be this as it will, it is manifest, that in both these places giants are spoken of as surmounters and wonders of the age, not of the common stature; and such instances we have had in all ages. There are many fabulous relations: such as we take to be that of *Thamiochus*, who is said to have been dug up anno 1713, and to have been higher than the tropics, and twenty-six feet long; and no better we suppose the giants to have been, which *Ol. Magnus* gives an account of in his fifth book; such as *Harthen* and *Starcher*, among the men; and among the women, reports it (*ish* *ist* *prole* *in* *capit* *valde* *ratu* *mariti* *induta* *filiole* *supra* *longitudinis* *ratio* *totum* *30* *latitudinis* *later* *homines* *longi* *Ol. Mag.* lib. 5. c. 2.

But, as for the more credible relations of *Goliath* (whose height was six cubits and a span, *1 Sam. xiv. 9.* which, according to *Bishop Cumberland*, is somewhat above eleven feet English), of *Maximianus* the emperor (who was nine feet high), and others in *Augustus's* and other reigns, of about the same height, to which might be added the dimensions of a helicon, dug up in the place of a Roman camp, near *St. Alban's*, by an unlearned *Marcus Antoninus*, of which an account is given by *Mr. Chetwood*, who judged by the dimensions of the house, that the person was eight feet high, *Phil. Trans.* N^o 319. Their antique examples and relations, we say, may be matched, my outcome, with modern ones; of which we have divers in *J. Loderph. Comment.* in *Hist. Athiop.* lib. 6. c. 2. sect. 22. *Magrus*, *Contingit*, *D. Hakewel*, and others; which last speaks from *Nunus*, of poets and poets belonging to the emperor of China, fifteen feet high; and of others from *Parcha*, of ten or twelve feet high, and more. See that learned author's *Anth.* p. 201.

The existence of a race of men above the common stature, on the coast of Patagonia, in South America, has been the subject of dispute for the two last centuries. In one century almost all navigators, of every country, affirmed that there were such persons, and in the next the fact is denied by the greater number, and their predecessors are treated as blind or boasting fabulists. The *Xera Garciaño de la Vega*, in his History of Peru, relates that, according to a tradition universally received, a number of vessels or junks came to St. Helena with a company of giants on board, of a stature so enormous, that the natives of the country were not higher than their knees; that their eyes were as broad as the bottom of a

plate, and their limbs proportionally large. But these are fables, similar to those relative to the same subject in other parts of the world. See *GIANTS* next.

Turner, the naturalist, reports that he had seen, near the river *Plata*, on the coast of *Brasil*, a race of giants, who went stark naked, one of whom was seven feet high; but he acknowledges that he saw no others. The ocular witness on the affirmative side of the question are, *Miguelin*, *Loaisa*, *Sarmiento*, and *Nodal*, among the Spaniards; *Cavendish*, *Hawkins*, and *Kuivert*, among the English; *Schald*, *De Noort*, *Le Maire*, and *Spilberg*, among the Dutch; and among the French, those who went in the expedition from *Marseilles* and *St. Malo*, in the year 1704.

Kuivert affirms, that he measured several dead bodies, which he found buried at *Fort Desfile*, which were from fourteen to sixteen spans high; and that he had frequently seen, at *Brasil*, one of the Patagonians, who, though a youth, measured no less than thirteen spans; and that the English prisoners at *Brasil* assured him, that they had seen many men of the same gigantic stature upon the coasts of the *Streights*; this account is also confirmed by *Schald* de *Witt*, and *Olivier de Noort*. *Ant. Casta*, a countryman on board de *Maire's* fleet, declares that he found, in the sepulchres on the coast of *Patagonia*, the bones of men who were between ten and eleven feet high. *Nodal* and *Mr. Richard Hawkins* merely relate, that these savages were a head taller than the inhabitants of Europe, and of such a stature, that the people on board their vessels called them giants.

Those who bear testimony to the contrary, are *Winter*, the Dutch admiral *Hermio*, *Froger* in *De Genes's* Narrative, and *Dr. John Narborough*. *Sir Francis Drake* also is silent with respect to the stature of the inhabitants of Patagonia; but *Winter* positively affirms, that the accounts of their being giants are falsehoods invented by the Spaniards. *Narborough* measured the skulls and the print of the feet of the *Guaycos* on the coast of the *Streights* of *Magellan*, which, he says, were of the common size; and he had often seen comparisons of them at *Port St. Julian*, who were neither taller nor bigger than other men. However, it may be observed, in general, that the greater part of those who hold the affirmative in this question, speak of people that inhabited the desert coasts of Patagonia to the east and west; and that, on the contrary, those who hold the negative, speak of those who inhabit the *Streights* upon the sides of the utmost point of America to the north and south. *Breker* relates, not from his own knowledge, but from the testimony of eye-witnesses, that there was, at a considerable distance within the country from the coast of *Chili*, an Indian nation, called by their neighbours *Gevoion*, who sometimes came down to the Spanish settlements, that were more than nine feet high, and were the same race with the Patagonians who live on the eastern coast. It appears, from various relations, that the inhabitants of the two borders of the *Streights* are of the common stature, and that the race, distinguished by the name of Patagonians, make their constant residence upon the desert coasts, scarcely accessible to any but themselves; and when European fleets frequented the *Streights*, they removed and retired in the interior part of the country; however, the current testimony of late navigators, particularly *Commodore Byron*, *Captain Wallis*, and *Captain Carteret*, will put an end to the doubts that have been hitherto entertained of the existence of such persons. *Commodore Byron*, who visited the coast of Patagonia in 1764, speaks of the inhabitants as of a gigantic stature; but he did not measure any of them, and only conjectured, by the proportion of their stature to his own and that of his companions, that they could not be less than six and a half, or seven feet in height, and proportionably strong and bulky. *Captain Wallis* had an interview with these people in 1766, and found, by measuring them, that the stature of the greater part of them was from five feet ten inches to six feet, though there were some who were six feet five, and six feet six inches, and one who was six feet seven inches. *Captain Carteret*, who attended *Captain Wallis* on this occasion, confirms the above account in his letter to *Dr. Mayer*. See *Phil. Trans.* vol. 52. art. 20. p. 20. See *See Hawkesworth's Voyag.* vol. 1. *Intro.* and p. 28. 1764.

GIANTS, *gigantes*, in ancient Mythology, were the sons of *Terra*, or the Earth, who made war against *Jupiter* and the celestial deities, to avenge the death of the *Titans*. These *giants* are represented as of an enormous height and size, and possessed of strength proportioned to their bulk: each of them had a hundred hands, and serpents instead of legs. Being determined to deluge *Jupiter*, they seized *Mount Ossa* upon *Tethys*, and *Olympus* upon *Ossa*, and from thence attacked the gods with huge rocks, some of which fell into the sea and became islands, and others

others fell on the earth and formed mountains. Jupiter summoned a council of the gods, and being informed that it was necessary to obtain the assistance of some mortal, with the advice of Pallas he called up Hercules, and with the aid of this hero, exterminated the giant Enceladus, Polybotes, Alcraon, Porphyrio, the two sons of Alorao, Epheides, Othos, Eurymas, Cleusar, Tythius, Pallas, Hippodamia, Agrius, Thoon, and Typhon, the last of whom it was more difficult to vanquish than all the others. Jupiter, having thus gained a complete victory, cast the rebels down to Tartarus, where they were to receive the full punishment of their enormous crimes: according to the accounts of some of the poets, he buried them alive under Mount Etna and different islands.

GIANTS' bones, a name too hastily given by the vulgar to certain bones and parts of skeletons, of an enormous size, found in England and other places. Of all the numbers of these, which have been publicly shewn about as wonders in nature, not one but has proved, on examination, a bone of an elephant, or else of a whale; the first, however, is usually the case, as the bones of elephants are much more frequently found buried in the earth than those of the whale. We had not long ago the first of a whale, now fossil, but recent, taken clean from the skin, and shewn about London for the head of a giant.

Sir Hans Sloane mentions a wrench of the tibia of a whale sent him from Oxfordshire, where it was dug up under ground, and afterwards used as a stool to sit upon, and vulgarly supposed part of a human back-bone. Now, if the whole size of the body had been calculated from this piece, the account would have been such a size as would have far exceeded all the fabulous stories of giants existing in the world.

Many skeletons of this kind have been found, which have been called the skeletons of giants: such are those of Philostratus, which are said to be the bones of men of twelve, twenty, and even thirty cubits high; that found in a mountain of Crete, and mentioned by Plato, forty-four cubits high; another of fifty cubits, found near Tanager in Mauritania, mentioned by Strabo, and supposed to be the skeleton of Antaeus; the skeleton of Pallas, found in Rome, and said to be taller than the walls of that city; another found in England in 1774, fifty feet long. Sir Austin Leake, in proof of the existence of giants before the flood, a grinders-tooth, which he saw on the bones of Uiter, which was in reality that of an elephant. The tooth in the church of St. Christopher, at Hippolis, and the flunder-bone of St. Christopher, preserved in a church at Venice, are of the same kind. The tooth preserved and shewn at Amberg, is only the grinder of an elephant; and another, belonging to a skeleton which was dug up near Tunis in 1636, was sent to the learned Heric, who took the impression of it in wax, and comparing it with the tooth of an elephant shewn near the place, found it to be of the same shape and size. Sir Hans Sloane has given an accurate and learned account of several other mistakes on this subject, for which we must refer to the Philol. Transact. N.º 202. However, Mout. Le Car, in a memoir not long since read before the Academy of Sciences at Rouen, recites a number of instances, in which skeletons, or parts of skeletons, of an enormous magnitude, have been found; these have been examined by anatomists, he says, and have been in their reported real bones; and hence he infers the existence of giants.

GIANTS' Caufway, a name given by the common people of the county of Antrim, in Ireland, to a vast quantity of that kind of black marble, called *asphaltum*, which finds in columns, and is natural to that marble, and runs out a great way into the sea.

The ignorance of the vulgar as to the nature of this stone, has occasioned this great pile of it to be supposed artificial, and the work of giants, once inhabitants there. But the truth is, that the basaltic, in whatever part of the world it is found, is always naturally of this figure. Whoever considers this amazing series of columns in Ireland, will be soon convinced no human hands could have formed them, and will find an accuracy in their figures, greater than could have been expected from the most cautious hand. The length of the several columns, and their joints so regularly placed in series, and the niceness of their articulations, by which no space or vacancy is left between, are wonderful.

Nature has been abundantly curious in the structure and formation of animal and vegetable bodies, but the fossils in general are less curiously put together; but this caufway of basaltic forms one of the works in this part of the creation, in which her greatest accuracy has been employed.

The single columns, of which this mass of piles consists, are sometimes octangular, sometimes of seven, or fewer

sides, but, generally, from three to nine sides only, when examined, they are found just such a mass of matter, as they are required in the places where they stand to fill up between others, so as to leave no vacancy. Each of these columns is composed of a great many joints of joints, each of which is so well fitted to the place, that the joining appears only a crack or crevice in the stone; yet these are regularly articulated, there being always a ball on one part, and a socket in the other to receive it, so that the joints cannot slip off from one another. The triangular and square columns are fewer in number than the others, but they stand principally in the most part of the large series, and are seldom seen, unless fringed after by a westerly eye.

The regular figure of the stone, composing this caufway, is not more wonderful than its quantity. (After several floors, at crystals, spars, and the remains of animals, such as *corals* and *striae*, are found only scattered thinly up and down; but nature has been profuse in this part of her workmanship, the whole country for many miles being full of it, and a wall made running no less than how far into the sea; far, besides what culture goes by the name of the *Green Caufway*, which itself of vast extent, there are great numbers of the same pillars at distance in other places.

There are two other smaller and imperfect caufways to the left hand of the great one, and farther in the sea, a great number of rocks show themselves at low water, which appear plainly all to consist of the same sort of columns. In going up the hill from the caufway, there are found, in different places, a vast number of the same columns; but these do not stand erect, but are laid slanting upwards in different angles and directions. Beyond this hill, eastward, also, at several distances, there stand a great number of the same pillars, placed straight and erect, and in clusters of different sizes. These are seen scattered, as it were, over the several parts of the hills.

One parcel of them is much admired, and called by the country people the *columns* or the *organs*. It stands in an elegant form, and faces the bottom of the hill. The columns, of which this cluster consists, are fifty in number, and they are so nicely put together, that the tallest stand in the middle, and the shorter gradually on each side of it to the end, so that they look like the ribs of a church organ viewed from the front. The tallest one of all these, which stands exactly in the centre, is fifty feet high, and consists of forty-four distinct joints. Five miles westward of the *Green Caufway* several ranges of tall pillars, of the same kind with those of the caufway, show themselves in clusters, and smaller piles standing for a long way on the sides of the rocks. A neighbouring church was built of the same of these pillars found thereabout; and this stone, on examination, proved to be the very same with that of the pillars of the *Green Caufway*. Other pillars have been observed at a still greater distance, so that their whole extent is not less than about eleven Irish miles, or fourteen English.

The inland pillars differ from those which run into the sea, and are called the *caufway*, only in the following particulars: some of the inland pillars are much larger than those of the caufway, being two feet and a half in diameter, and among these there are only found such as have three, four, five, and six sides, none of them having yet been found to have seven or eight sides, as many of those of the caufway itself have. And finally, these inland pillars, though composed of as many joints as those of the caufway, yet have not that convex articulation of the ball and socket, but are only joined by the laying one smooth surface on another; so that a joint of a single column may be slipped off from the rest, by a considerable force pressing against it. There is something like this observable also in some of the columns of the caufway itself, for among the numbers which are joined by the ball and socket, there are some which only adhere by being applied surface to surface. This is found only in a few of the columns, however, and they always stand within the clusters, and are composed of less than seven sides. In these also the joint is not made by the application of two horizontal planes, but by such as slant, so that it looks very like the breaking of an *entrecroix* or *striae*, or some other such fatty body of extraneous or animal origin.

Great numbers of the upper ends of the columns, which compose the caufway itself, are hollowed at the top, as if intended to receive another joint with a ball at its end, or as if such a joint had fallen off from them. These hollows are of great use to the neighbouring poor, for they make a kind of glass of them, and thus they easily procure themselves a kind of bay-water in summer. They fill these little basins with sea-water at high tides, and the heat of the sun and of the stone contributing greatly to the evaporation, as well as the thickness of the

the below, the whole luminosity is found evaporated in the time of four tides, and they take out the salt ready for use. The joints, of which these pillars consist, are generally convex at one end, and concave at the other; the flat part serving as a ball for the socket of the joint next below, and the other as a socket for the ball of the joint next above. But this is not an unalterable law in their formation; for there are joints found which are convex at both ends, and others which are concave at both ends to receive balls, or queer sockets both ways. The vast height of these straight-jointed pillars, especially of the more slender and perfect ones, is amazing. Forty feet is a very considerable height for a pillar, of perhaps less than a foot in diameter, yet this is far from being the whole real length of the pillar, for this appears above ground, but what is buried in the earth is not yet known. Some curious people have dug down eight feet at the base, and found the column ran in the same shape and regularity to that depth; and there appeared no room to doubt of its having gone in reality much farther.

The joints, as we see the pillars above the surface, are usually as many in number, as the pillar is feet high; but they are not regularly each of a foot long, for they are thickest at the upper part of the column, and gradually longer and longer as they approach the base. This is observed both in the island-columns, and in those of the casleway; but though the length of the joints differs, their convexities and hollows are much the same in all parts of the column.

It is to be observed, that where the top of any pillar seems complete, and no part to have been broken off, the summit of the topmost joint is usually flat and smooth, not even having provided any convexity or cavity in a part where it had no use.

There remains a very great difficulty to conceive by what means the three joints, so bulky and ponderous, and so perfectly distinct, and distinguished bodies from one another, could arrive at the places where they now are placed, or be carried to the tops of such high columns; but when we consider many other natural phenomena, we shall find to many things equally wonderful, that this will not appear the least work of nature because it is beyond our comprehension.

Dr. Richard Pococke endeavours to account for the joints in these pillars, by supposing that the several parts of the pillars were at first formed either in the shape of a cylinder, with the upper end, if not both ends, of a spherical figure; or that they were either spherical or oblate spheroids. For the pillars being composed, as he imagines, of crystal of six sides, and four of three, and of a very fine black lime, he apprehends that as the crystals and parts united, and formed an irregular body, the fine black sand filled up the interstices, and formed such cylindrical or spherical bodies in a flat state, but in this horizontal lamina or plates like state; because they mostly appear to be of this figure, the bones separate in such plates between the joints and those parts of the pillars which have been exposed to the weather and corroded by it appear in such plates; though in some cases there are perpendicular joints, as in a remarkable pillar which seems to be split through its whole length. It is, therefore probable, says Dr. Pococke, that, when this matter was in a fluid state, and when the stratum of rock was formed, on which it was made, the fluid contiguous to the rock continued in motion; that, after a time, some of the particles of matter, which compose these pillars, being disengaged from the particles of water, ceased to move and formed the parts of these pillars, which are next to the rock; in the above mentioned figures; so much being formed only at once, or in a very short time, as extends to the first joint; and then, either by change of season, or some other accident, so much more water mixed with these particles, as prevented their continuing to form themselves into such a shape and gave the former motion; that, afterwards, the decrease of the water might again be the cause of the former effect, and so on, till the pillars were formed; and the top of the last part was formed being convex, that which was formed upon it would probably be concave and adapt itself to it, either by its gravity being faster. Whilst all were in one or other of these figures, the gravitation of the second stratum above the first joint might operate in such a manner as that which was first formed, and fill fast, as to press it down; and thus eight bones being round one stone would naturally press the middle bone into the form of an octagon.

The internal substance of the stone composing these columns is extremely hard and compact. Its green, or grain, is so very fine, that the eye does not perceive it, unless examined very nicely, and that in the surface of a piece newly broken. It then shews itself like a very fine

glittering sand, thickly interperfed among a more opale matter; the whole is heavier than almost any other simple stone; yet it contains not the least particle of any metal so far as has been discovered. It is the purest and most homogeneous of any stone of this country; having no extraneous matter, no tincture of the animal kind in it, such as shells, entrocha, and the like, which are well known to be very common in the various strata of stone, in Ireland, and in many other parts of the world. However, Mr. Drury, well known for his models of several stones of this casleway, and his engravings of the prospects of the casleway itself, found in one of the flours a rough pebble in the shape of an egg, about 1 of an inch long, and above an inch thick; which, when it was polished, proved to be a white corallian.

Marble, in general, are very subject also to cracks, which, when filled up, as they usually are with sparry matter, make a sort of white vein; but such cracks and veins are not to be seen in the marble of these columns.

It has been tried in a glass-house, and found to melt with help, so as to make the black glass bottles.

From these observations some have concluded, that there is an analogy between this marble and crystal in their origin and formation, as the columns of crystal are alike pure and homogeneous, alike of a regularly angular figure, and both are alike free from veins, cracks, and extraneous substances. See Philol. Trans. N. 109, 212, 241. Lowth. Abing. vol. II. p. 514, 560. Phil. Trans. vol. XLIII. vol. XLIV. art. 34 and 35. See also the article TORRENTS.

There are other prismatic columns, similar to those above described, in our own island; particularly in the mountain of Caeridiff, near Dolgelly, in Merionethshire; where they probably form a group as in other places. Mr. Strange has given an account of two groups of prismatic basaltic columns, which he discovered in the Venetian state, in Italy: one in Monte Rosso, about seven miles nearly south from Padua, and the other in Monte del Diavolo, near San Giovanni Marone, about ten miles north-west of Vicenza. The form of the latter is nearly circular, resembling that of the Giant Columns; that of the former approaching more to an oblong or oval figure: the columns of San Giovanni are much about the same size, and measure about a foot in diameter; those of Monte Rosso are very unequal, some being a foot, while others scarcely exceed three inches in diameter: those of both these Venetian groups manifest all the varieties of prismatic forms observable in the Giant Columns, and other such groups; but they are commonly of five, six, or seven sides, and the hexagonal form seems mostly to prevail. The texture of the former sort is solid and uniform; the surface smooth, and the internal parts of a dark iron-grey colour; those of Monte Rosso have a rough and knotty surface; and, when broken, manifest a variegated colour, and unequal texture of parts; resembling an inferior sort of granite, of which the mountain is formed, and which serves as a ball for this range of columns.

Other groups of articulated basaltic columns have also been observed in the province of Velay and Auvergne in France; particularly by M. De Varennes, at Bland near Langeac, and by M. Desmarest, near St. Mont d'Or; and M. Sage mentions another near St. Alcan, in the same province. Kircher has long ago described a group of the same columns near Viterbo in Italy, Mundus Subterr. lib. viii. §1. cap. 15, &c. And Mr. Strange mentions another at Castel Nuovo, in the Euganean hills, about four miles south-west of that of Monte Rosso. The systematic mineralogists have, generally, assigned the same common origin to most lapideous solids, which they suppose to be generated by deposition from an aqueous fluid; but the structure and other phenomena of these basaltic columns prove them to be crystallizations or concretions of a particular kind, and generated immediately from an igneous fluid; and to be the effects of some intrinsic principle of organization, as Mr. Strange imagines, by which they appear to have been produced simultaneously, in a manner, upon the consolidation of the whole mass of matter, in which they lie, and with which they constantly bear the greatest analogy; and he supposes, that these regular bodies have been generated locally, and not in the midst of those violent convulsions of nature, which are commonly assigned for the origin of volcanic mountains in general. Phil. Trans. vol. LX. part I. art. 2. p. 75, &c. vol. LX. part II. art. 4. p. 345, &c. See BASALTES.

GIAR *alabastr*, in *Babylon*, a name given by Avicenna, Serapion, and the rest of the Arabian writers, to the potamogiton of those times. This is mistaken by some the water-ruth, but that it is founded on an error; it is certain that the plant thus called by the Arabians, was very different from the potamogiton of our times. Avicenna

tells us, it had flowers resembling those of the water-lily; and it seems either to have been the *lagitta aquatica*, or water arrow-head, or else the butomus, or some of the smaller species of *nymphaea*.

GIAROLA, in *Ornithologia*, the name of a bird of the falk kind, remarkable for its very long beak. It is of the size of the common lark. Its head, neck, back, and wings, are of a mottled colour, resembling that of the quail. The general colour of the feathers is a chestnut brown; and their edges are variegated with white, yellow, and red; the back part of its head has a sort of crown or ring of white feathers; its belly is white; its tail is so short that it seems to have none; it is timid, however, and is elegantly variegated with chestnut colour and white. Aldrovand. de Avibus, lib. xvii. cap. 30.

GIAROLO, in *Ornithologia*, a name by which a small bird of the lark kind, remarkable for its white tail, is known in the markets of Italy. It very much resembles the bird we call in English the *stirner*, but its beak is broad at the base, and tapers to a point, and its legs are thicker and shorter. It is not known among authors by any Latin name, except that Aldrovandus has called it the *cinctus terminis*, and cinetus is a very indeterminate name, being applied by different authors to several different birds.

GIB, in *Medicina*. See CRANE.

GIBBOUS, in *Surgery*, is used to denote a person bunched or hump-backed.

GIBBOUSITY is a preternatural incurvation of the spine dors either backward, or on one side. Infants are more subject to this disorder than adults, and it often proceeds from external than from internal causes. A fall, blow, or the like violence, frequently thus distorts the tender bones of infants. When it proceeds from an internal cause, it is generally from a relaxation of the ligaments that sustain the spine, or a caries of its vertebrae; though the spine may be indented forward, and the back thrown out, by a too frequent and repeated action of the abdominal muscles; and this, if not timely redressed, usually grows up, and fixes, as the bones harden, till in adults it is totally irremediable: but when the disorder is recent, and the person young, there are some hopes of a cure. The common method is by a machine of pasteboard, wood, or steel, which is made to press principally upon the gibbous part, and this, by long wearing, may set it right. The surgeons, however, have a different instrument, which they call a cross, much more efficacious, though not quite so convenient in the wearing; by the use of this, the parts are always prevented from growing any worse, and are often cured. During the application of these assistances, the parts should be at times rubbed with Hungary-water, spirit of lavender, and the like, and defended with a strengthening plaster of oxytocum, opodeldoc, or the like. Heister's Surg. part ii. p. 21.

That part of the liver, out of which the vena cava arises, is also called the *gibbus* part.

GIBBOSITY is also used in reference to the enlightened part of the moon, while she is moving from full to the first quarter, and from the last quarter to full again; for all that time the dark part appears horned, or falconed, and the light one bunched out, convex, or gibbous.

GIBBOSA fish, *gibbosa piscis*, in *Ichthyologia*, a name given by Mr. Ray to the fish called by the Dutch *trampog*. It is a smooth fish without scales; its belly is white; its fins and tail black. It grows to a considerable size, sometimes to four feet. It is caught all over the East Indies, near the sea shores, and is very firm, and much esteemed as food. It has its name from the remarkable rising of its back, which is like that of the perch, but much higher. Ray's Ichthyology. Append. p. 4.

GIBBELINS, **GIBELICINI**, **GIBELLINI**, or **GIBELINI**, a famous faction in Italy, opposite to another called the *Guelphs*.

The *Guelphs* and *Gibellins* ravaged and laid waste Italy for a long series of years: so that the history of that country, for the space of three centuries, is only a detail of their mutual violences and mortal wars.

The *Guelphs* strenuously asserting the power of the see of Rome, as the *Gibellins* did the emperor's right of sovereignty.

We have but a very obscure account of their origin, and the reason of their names: the generality of authors affirm, that they rose about the year 1240, upon the emperor Frederic II's being excommunicated by pope Gregory IX.

These princes, say they, making a tour among the cities of Italy, gave the name of *Gibellins* to such as he found well affected to him; and that of *Guelphs* to those who adhered to the pope. But as to the reason and signification of these words, there is a deep silence; *Gibellins* might possibly be formed of *gibellus*, *imperator*; whence *gibellus* fish, *imperator*. Of *guelphus*, the Italians might

Vol. II. N° 151.

make by corruption, *Gibellus*; so that *Gibellins*, in this light, should be the faction with *imperialists*, or such as followed the emperor's party.

By the way, some writers maintain, that the two factions arose ten years before; though still under the same pope and emperors.

Other historians relate that Conrad III. marching into Italy, in the year 1139, against the Neapolitans, Roger, count of Naples and Sicily, in order to defend his state, called to his assistance *Guelph*, duke of Bavaria; and one day, when the two armies were ready to join in battle, the Bavarians cried out in high Dutch, *his Guelph!* or, as others say, in Flemish, *his Guelph!* that is *his Guelph!* and that the Imperialists answered on their side, with the words *his, or his, Gibellus here, Gibellus!* calling the emperor by the name of the place where he had been bred.

Hornius refers the names to the war in 1145, between Henry the Proud, duke of Bavaria and Saxony, and Conrad III. duke of Swabia; the two princes preparing to engage near the town of Wittenberg, the Bavarians began to cry out *Guelph*, which was the name of duke Henry's brother; and the partisans of the emperor *Welshelien*, which was the name of the place where that prince was born and bred, in the duchy of Wittenberg, whose surname he bore: from which *Welshelien* the Italians at length formed *Gibellus*.

This account is confirmed by Martin Crusius: *Isidori Gibelini (Hilarii) patria Conrad regis & Wislone consensuensis*. Conrad being of Welshelien, that word, says Crusius, gave rise to *gibelinus*, and that to *gibelinus*, *Gibellus*, *Gibellini*.

Platina, on the other hand, asserts, that the name *Gibellus* arose from that of a German at Philopoli, whose brother, named *Guelph*, gave likewise his name to the opposite faction: the two brethren, it seems, bearing an irreconcilable hatred. Others maintain, that the emperor gave the appellation *Gibellus* to those of his party, from the German word *gipfel*, signifying ridge, or tip; because the empire rested on them, as the rafters of a house lean on the ridge, which joins them a-top.

Karus, a learned canon of Stralbourg, in the lives of the emperors of the house of Brunswick, is of the second opinion above related: in a battle, says he, between Wolf, or Guelph, and Frederic, the army of the first crying out, *his Wolf!* *his Wolf!* the second commanded his to cry out, *his Gibellus!* *his Gibellus!* the name of his birth-place; and the French and Lombards asking the signification of those words, they were answered, that by *Wolf* was meant the pope's party; and, by *Gibellus*, the emperor's.

Yet others contend, that the word *Gibellus* is only a softening of the word *gibelius*, or *gibelinus*; and that it arose from Gulpert, an antipope, set up by the emperor Henry III. in the year 1080.

Among many other conjectures, Maimbourg, in his *Hist. de la Decad. de l'Emp.* advances another opinion, that the two factions, and their names, arose from a quarrel between two very ancient and illustrious houses on the confines of Germany, that of the *Henrys of Ghibellin*, and that of the *Guelphs of Adorf*. See *Mai chival*.

It is said by some, that the *Gibellins*, when driven out of Italy, long after the year 1220, at which period the contest between them and the *Guelphs* ran very high, and settled at Amsterdam, were the inventors of the mercantile practice of re-exchange, or re-exchange, on bills of exchange, on account of the damages and charges they were put to, and the interest of the money of their bills protested, which had been given to them for the effects they had been obliged to leave behind them. Anderson's *Hist. Commerce*, vol. i. p. 110.

GIBET, or **GIBALT**, a machine in manner of a gallows, whereon notorious criminals, after execution, are hung in irons, or chains: as spectacles, in terror.

The word in French, *gibet*, properly denotes what we call *gallows*: it is supposed to come originally from the Arabic *gibul*, *munt*, *elevation of ground*; by reason *gibets* are usually placed on hills, or eminences.

GIBLETS, the offals, or entrails of a goose; including the heart and liver, with the feet, gizzard, &c.

The word is supposed to be formed of *gibellus*, from the French *gibellus*, *mischievous*.

Giblets make a considerable article in cookery: they boil *giblets*, stew *giblets*, make ragouts of *giblets*, *giblet-pies*, &c.

GIBUR, a general name given by some chemical writers, to all medicines drawn by their art from metallic or mineral substances.

GIDDINESS, the popular name for the distemper called by physicians *vertigo*.

Giddiness in horses is cured by a glyster and blood-letting.

to be repeated after two days moderate exercise. *Didl.*
Ruil. in voc.

GIFT MEHL, the name given by the German chemists and metallurgists, to the first appearance of arsenic, or the grey flowers arising from the roasting of cobalt, and flicking to the long wooden funnel, which they carry from the furnaces. The grey colour of these flowers is occasioned by the fumes of the fuel, and when they are afterwards sublimed in a close vessel, the arsenical flowers begin to grow clammy in that part of the vessel which is last made hot by the continuation of the fire, and there form themselves into a ponderous thick sublimata.

Nevertheless, this sublimata neither runs out, nor gets to the bottom of the vessel when the fire is increased. A tenacious doughy clamminess is indeed communicated to arsenic by the fire; but the fire alone cannot make it melt, but resolves it into a fume, which, when it can find no way to escape, often bursts the vessels in which it is confined.

The yellow arsenic, which has one tenth part sulphur, is by that mixture much more easily formed into a solid sublimata than the white arsenic alone; but the red arsenic, which contains double that quantity of sulphur, cannot easily be formed into a sublimata by ascent, because of its extreme readiness to fuse. The best way of preparing this is therefore to raise it out of a retort in the large and long neck of which it may be condensed, and thence fall while yet fluid into the receiver. Arsenic of this kind may be immediately produced out of some species of pyrites, without any previous addition; or by mixing a sulphurous pyrites of the common kind with one of the white ones, or with any other ore of arsenic; and by this process there will be separated an arsenic, either yellow or red, according to the smaller or larger proportion of the sulphur in the mixture of the whole.

The word *gift mehl*, is German, and signifies poisonous meal or flour.

GIFT, *donum*, in Law, is a conveyance which passeth either lands or goods, and is of a larger extent than a grant, being applied to things moveable and immovable; yet as to things immovable, when taken strictly, it is applicable only to lands and tenements given in tail; but *gift* and *grant* are often confounded. See DONATION.

A *gift* may be by deed, by word, or in law: thus all a person's goods and chattels, except in some special cases, may be given without deed; though such a gift is liable to suspicion. When such a gift is made in satisfaction of a debt, it should be done before witnesses of credit; the goods and chattels should be, at the same time, appraised to the full value; and the gift be expressly made in full satisfaction of the debt. As to *gifts* in law; if a man be married, all the goods and chattels of his wife belong to the husband: also, if a person be made executor of a will, by gift in law, all the testator's goods are his, after paying the testator's debts. And as to deed of gift, all things that be in livery, as messuages, lands, woods, &c. may be given or granted in fee, for life or years, at first; and be assigned over for ever afterwards. Such a deed may be made upon condition; and if it be of goods and chattels, the delivery of a *livery* is a good seal of the whole.

GIG-FISH. See FISH-GIG.

GIGANTIC. See GIANT.

GIGANTOMACHIA, the battle of the giants against the fabulous gods of the ancient heathens.

The word is Greek, *γίγαντες*, formed of *γίγας*, *gigas*, giant; and *μαχη*, combat, of *μαχομαι*, *gigas*, I fight.

Several of the poets have composed *gigantomachias*: that of Scarron is the finest of all his pieces.

GIGAROS, in *Botany*, a name given by some writers to the dracunculus.

GIGARTON, the skin or kernel of a grape or raisin.

Egineta observes, that grape-stones are drying and refrigerating; and the fumes of raisins, on analysis, afford an acid spirit, and empyreumatic oil, and, as some say, a very considerable quantity of a volatile salt.

GIGERIE, a term used by some writers, to express the offals of poultry of any kind, including the intestines, extremities, and whatever else is thrown away before the dressing. See GIBBET.

GIGG, *GIGA*, or *IG*, in *Musical and Dancing*, a gay, brisk, sprightly composition, and yet in full measure, as well as the allemand, which is more serious. Menage takes the word to arise from the Italian *giga*, a musical instrument mentioned by Dante.

Others suppose it to be derived from the Teutonic *gig*, or *gighe*, a *valde*. This is a favourite air in most nations of Europe: its characteristic is double time, marked 2, or 3: it consists of two strains, without any determinate number of bars.

GIGGS, among *Farriners*, small bladders, or bladders, on the inside of a horse's lips. They must be laid open, and cleansed with salt and vinegar, or alum-water.

GIGGLE, in the *Manufacture of Flax*, denotes a hole made in the earth, where fire is made to dry the flax laid over it.

GIGMILLS, a kind of fulling mill, for fulling and burling of woollen cloth, prohibited anno 5 and 6 Ed. VI. c. 22.

GIGOT, in the *Mange*, a branch after the form of a *gigue*, or leg, is a *BRANCH*, the lower part of which is round, and called in French *gargouille*.

GILAM-HIO, in the *Alutria Medica*, a name used by some authors for a peculiar sort of the *linum-aloes*, which is soft, whitish, and very sweet-tasted.

GILARUM, in *Botany*, a name used by Marcellus, for the *SERPILLIUM*.

GILBERTINES, an order of religious, thus called from St. Gilbert, of Sempringham, in the county of Lincoln, who founded the same about the year 1148: the monks of which observed the rule of St. Augustine; and were accounted canons; and the nuns that of St. Benedict. The founder of this order erected a double monastery, or rather two different ones, contiguous to each other, the one for men, the other for women, but parted by a very high wall.

St. Gilbert himself founded thirteen monasteries of this order, viz. four for men alone, and nine for men and women together, which had in them seven hundred brethren, and fifteen hundred sisters. At the dissolution there were about twenty-five houses of this order in England and Wales.

GILD, or **GUILD**, originally signifies a fraternity or company.

The word is formed from the Saxon *gildan*, *i. e.* to pay, because every man was *gildan*, *i. e.* to pay something towards the charge and support of the company. Hence also our *Guildhall*, *q. d.* the hall of the society or fraternity, where they meet, and make orders and laws among themselves.

The original of *gild*, or *guild*, is thus related: it being a law among the Saxons, that every freeman of fourteen years old should first foreswear to keep the peace, or be committed; certain neighbours, consisting of ten families, entered into an association, and became bound for each other, either to produce him who committed an offence, or to make satisfaction to the injured party: that they might the better do this, they raised a sum of money among themselves, which they put into a common stock; and when one of their pledges had committed an offence, and had fled, then the other nine made satisfaction out of this stock, by payment of money, according to the offence.

Because this association consisted of ten families, it was called a *decimaria*; and from hence came our later kinds of fraternities.

But, as to the precise time when these *gilds* had their origin in England, there is nothing of certainty to be found; since they were in use long before any formal licence was granted to them for such meetings.

It seems to have been about the close of the eleventh century, says Anderson, in his History of Commerce, vol. I. p. 70, that merchant-gilds, or fraternities which were afterwards styled corporations, came first into general use in many parts of Europe. Mr. Madox, in his *Firma Burgi*, chap. I. § 9. thinks, they were hardly known to our Saxon progenitors, and that they might be probably brought into England by the Normans; although they do not seem to have been very numerous in those days. The French and Normans might probably borrow them from the free cities of Italy, where trade and manufactures were much earlier propagated, and where, possibly such communities were first in use. See CITY.

Edward the Third, in the fourteenth year of his reign, granted licence to the men of Coventry, to erect a merchant's *gild* and fraternity of brethren and sisters, with a master, or warden; and that they might found chantries, bellow alms, do other works of piety, and constitute ordinances touching the same.

So Henry the Fourth, in his reign, granted a licence to found a *gild* of the Holy Cross, at Stratford upon Avon. **GILD**, in the royal boroughs of Scotland, is still used for a company of merchants, who are freemen of the borough.

Every royal borough has a dean of *gild*, who is the next magistrate below the bailiff. He judges of controversies among men concerning trade; disputes between inhabitants touching buildings, lights, watercourses, and other nuisances; calls courts, at which his brethren of the *gild* are bound to attend; manages the common stock of the *gild*; and amerces, and collects fines.

GILD, or GELD, according to Camden, also signifies a tribute, or tax. See GELD.

GILD, according to Crompton, also signifies an amercement. As in *loose-gild*, which he interprets a ptection within the forest.

Hence, to be quit of all manner of *gild*, is to be discharged from all manner of ptections to be made for gathering sheaves of corn, lamb, and wool, to the use of foresters.

GILD, or GELD, is also used among our ancient writers for a compensation, or mulct, for a fault committed. See URGELD.

Hence, *urgeld* is the price of a man; *urgeld* is the price of cattle; *urgeld*, the single value of a thing; *urgeld*, the double value, &c.

There are divers other words which end with *gild*, and shew the several kinds of payments; as *dovegild*, *vold-gild*, *sew-gild*, *horegild*, *figgild*, *penegild*, &c. which see.

GILD, or GUILD *rent*, are rents payable to the crown by any *gild* or fraternity; or such rents as formerly belonged to religious *gilds*, and came to the crown at the general dissolution: being ordered for sale by the stat. 22. Car. II.

GILDABLE, or GELDABLE, denotes a person tributary, that is, liable to pay tax, or tribute.

Camden, dividing Suffolk into three parts, calls the first *gildable*, because liable to tax; from which the two other parts were exempt, because ecclesiastical.

GILDABLE is also explained in an ancient MS. to be that land or lordship which is *sub distributione curie vicium*.

GILDER. See GUILD.

GILDMALDA *Tentorium* was used for the fraternity of Eastering merchants in London; called also the *STILLYARD*.

GILD-HALL, *q. d.* *Gilde aule*, the chief hall in the city of London. See GUILD-HALL.

GILD-MERCHANT, *gilda mercator*, was a certain privilege, or liberty, granted to merchants, whereby they were enabled, among other things, to hold certain pleas of land within their own precincts.

King John granted *gildum mercatorum* to the burgesses of Nottingham.

GILDING, or GUILDING, the art, or act, of spreading or covering certain substances with gold, either in leaf, or in amalgam with quicksilver.

The art of *gilding* was not unknown among the ancients, though it never arrived among them at the perfection to which the moderns have carried it.

Pliny assures us, that the first *gilding* seen at Rome, was after the destruction of Carthage, under the censorship of Lucius Mummius, when they began to *gild* the ceilings of their temples and palaces; the Capitol being the first place on which this enrichment was bestowed. But he adds, that luxury advanced on them so hastily, that in a little time you might see all, even private and poor persons, *gild* the very walls, vaults, &c. of their houses.

We need not doubt but that they had the same method with us, of beating gold, and reducing it into leaves; though, it should seem, they did not carry it to the same height; if it be true, which Pliny relates, that they only made seven hundred and fifty leaves, four fingers square, of a whole ounce. Indeed he adds, that they could make more; that the thickest were called *brutae Prae-nissinae*, on account of a statue of the goddess Fortune at Praeneste, gilt with such leaves; and that the thinner were called *brutae quassinae*.

The modern gilders also make use of gold leaves of divers thicknesses: but there are some so fine, that a thousand do not weigh above four or five drachms. The thickest leaves are used for *gilding* on iron, and other metals; and the thinnest on wood. But we have much advantage above the ancients, in the manner of using and applying the gold: the secret of painting in oil, discovered of late ages, furnishes us with means of *gilding* works that shall endure all the injuries of time and weather, which to the ancients was impracticable. They had no way to lay the gold on bodies that would not endure the fire but with whites of eggs, or size; neither of which will endure the water: so that they could only *gild* such places as were sheltered from the moisture of the weather.

The Greeks called the composition on which they applied their *gilding* on wood, *leucophorum*, or *leucophorum*; which is described as a sort of glutinous compound earth, serving, in all probability, to make the gold stick, and bear polishing. But the particulars of this earth, its colour, ingredients, &c. the antiquaries and naturalists are not agreed upon.

There are several methods of *gilding* in use among us; viz. *gilding on an oil size*, *gilding on a water size*, *gilding by the fire*, which is peculiar to metals; *gilding of book*, &c.

Method of GILDING in oil, or on an oil size. The basis of matter whereon the gold is applied, in this method, according to M. Pellicien, is the remains of colours found settled to the bottom of the pots wherein the painters wash their pencils. This matter, which is very viscid, they first grind; then pass it through a linen cloth; and thus lay it with a pencil on the matter to be gilt, after having first washed it once or twice over with size; and, if it be wood, with some white paint.

But however this method may obtain in France, the English *gilders*, in lieu heretofore, generally make use of a gold size, made of yellow oxen, ground fine with water, and laid to dry, on a chalk-stone; and then ground up with a due proportion of fat drying oil, to give it the body or degree of fluidity required.

Linseed oil may be prepared for this purpose, by putting such a quantity of it into a broad vessel as may cover the bottom about an inch deep, and adding to it as much water as will rise six inches or more above the bottom. Let the vessel be exposed to the sun and rain, and the contents be occasionally stirred for five or six weeks, till the oil appear of the consistence of treacle. Then separate the oil from the water, and place it in a long bottle or separating funnel used by the chemists, in such heat as will render it perfectly fluid; pour off the clear part, and strain the remainder through a funnel, and the whole will be fit for use. The water helps to clear and bleach the oil, and improve it in other respects.

If the piece to be *gilded* has not already had a coat of oil paint, prime it with the above composition, to which a small portion of vermilion may be added. When the priming is dry, the next operation is *fining* the work; which may be done by laying the above size on the fat oil, mixed with the *Japaner's* GOLD-SIZE, thinly over the work to be gilt, by means of a brush, or a large pencil: but care should be taken that the brush or pencil be made to pass into all the cavities and projecting parts, if the subject be carved. When great perfection is required, the work should be *fined* a second time, and some add a third *fining*.

When the work is almost dry, but while yet unskilful enough to catch and retain the gold, the workmen spread their gold leaves thereon, either whole or cut in pieces.

To take up and apply the leaves, they make use of a piece of fine, soft, well-carded cotton; or of a pallet for the purpose, or barely the knife, wherewith the leaves were cut, according to the parts of the work they are to *gild*, or the breadth of the gold to be applied.

In proportion as the gold is laid, they press it down smooth with a bunch of cotton, a hare's foot, or squirrel's tail, to make it stick, and, as it were, incorporate with the ground; and with the same hare's foot, or a camel's hair pencil, they mend any cracks that may happen therein, after the same manner as will be hereafter shown in *Water-GILDING*.

The squirrel's tail used in *gilding* is cut short, and sometimes spread in the fan-fashion, by means of a piece of wood formed like a pencil-lick, but broad at both ends, and split to receive the tail; but it will equally serve in its own form, when the hair is cut to a proper length. The cotton also should be formed into a ball, by tying it up in a piece of fine linen rag; for if it be used without the rag, the fibres adhere to the gold size, and embarrass the work. Small pieces of the gold leaf may be applied to those parts of the work, which the squirrel's tail and cotton cannot reach, by the point of a fine pencil, first breathed upon, and thus conveyed to their proper place. When the whole of the work is covered and dry, it may be brushed over with a camel's hair pencil, or soft hog's-hair brush, to take off from it all loose parts of the gold.

This sort of *gilding* is chiefly used for domes, and the roofs of churches, courts, banqueting-houses, &c. and for figures of plaster, lead, &c. that are to stand exposed to the weather.

Method of GILDING on a water size. Water *gilding*, or burnish *gilding*, is not performed without more apparatus; nor is it used so frequently, nor on such large works as the former: wooden works, and those of stucco, are almost the only ones gilt in this way; which, besides, must be sheltered from the weather. The size made use of for *gilding*, is to be made of shreds, &c. of parchment, or gloves, boiled in water, in the proportion of about a pound of the shreds to six quarts of water, to the consistence of a jelly, and then strained through flannel while hot.

If it be wood that is to be gilt, those parts that admit of it being first well rubbed with fish-skin, and then with Dutch ruther, it is primed with the above size, mixed with as much whiting as will give it a tolerable body of colour; and this mixture is made by melting the size, and

and frowning the powdered whiting into it gradually, and well stirring them together. For this whiting, some use plaster of Paris, well beaten and sifted; others Spanish white, or ceruss, &c. It is laid on with a stiff brush, and oftener or seldom repeated, according to the nature of the work: for pieces of sculpture, seven or eight lays suffice; for flat, or smooth works, they use ten or twelve. In the latter case they are applied by drawing the brush or pencil over the work: in the former, by dabbing it smartly on, that the fire may enter all the dents of the carving.

After the last coat is laid on, and before it be quite dry, a brush pencil, dipped in water, should be passed over the whole, to smooth it, and take away any inequalities that may have been formed; and when it is dry, the parts that admit of it should be again brushed over till they are perfectly even. The work should then be repaired, by freeing all the cavities from the priming; after which a water polish should be given to the parts designed to be burnished, by rubbing them gently with a fine linen rag, moistened with water.

The white thus finished, they proceed to yellow it, observing, that, if it be a piece of sculpture in relief, they always first touch up and repair the several parts, which the white ground may have disfigured, with little iron instruments, as graters, chisels, gouges, &c.

The yellow which they use is only common ocher, well ground and sifted, and thus mixed up with the size used for the white, only weaker by one half. This colour is laid on hot, and, in works of sculpture, it serves to supply the place of gold, which frequently cannot be carried into all the cavities and denings of foliages and other ornaments.

Over this yellow, which is now often omitted, is applied a lay, which is to serve for the ground whereon the gold is to be immediately laid; for the preparation of which, see *GOLD-FACE*. The ingredients being all ground together with warm size, mixed with two thirds of water, they apply two or three lays of the composition upon the yellow, each after the other is dried, taking care not to put any in the small cavities of the work, to hide the yellow. Some add a little vermilion to the *glazing* size. The brush used in this application is to be soft; and when the matter is well dried, they go over it with a stronger brush or soft cloth, to rub it down, and take off the little prominent grains, and thus facilitate the burnishing of the gold.

In order to proceed to *gild*, they must have three sorts of pencils; one to wet, another to touch up and amend, and a third to flatten: there is also required a cushion, to spread the gold leaves on when taken out of the book; a knife to cut them; and a hare's foot, or squirrel's tail, fitted with a handle, or else a piece of cotton, to take them up, direct, and apply them.

They begin with the wetting pencils, by which they moisten the layer last laid on with water, that it may be better receive and retain the gold: the leaves are then laid on the cushion, and taken up, if whole, with the squirrel's tail; if in pieces, with the other instrument, or even the knife with which they are cut, and laid and spread gently on the parts of the work before moistened. When the leaves happen to crack or break in laying on, they make up the breaches with little pieces of leaf taken up on the repeating pencil; and with the same pencil, or another somewhat bigger, they smooth the whole; pressing the gold into the dents, where it could not so well be carried with the squirrel's tail.

The work being thus far gilt, when dry, and fit for the purpose, which it will usually be in about twenty-four hours, remains either to be burnished, or matted.

To burnish it, is to smooth and polish it with a burnisher, which is usually a dog's or wolf's tooth, or a blood-stone, an agate, or a pebble, or something else very smooth, fitted in a handle for that purpose.

To mat, is to give it a light lark, in the places not burnished, with a pencil dipped in size, wherein a little vermilion sometimes has been mixed. This helps to preserve it, and prevent its flaking, when handled.

Some recommend for this purpose red lead, with a little vermilion ground with the white of an egg; but yellow ocher, or Dutch pink, with red lead, would better answer the end; or the *terra di Siena*, very slightly burnt, or mixed with a little red lead, would have a much better effect, and be more durable than any other mixture to near the colour of gold in shade. Murphys fire will likewise supply the place of the white of eggs. This operation of matting supercedes the necessity of yellowing, which is intended to give the appearance of *gilding* to the deeper and obscure parts of the carving where the gold cannot, nor is it thought necessary to be laid on.

The last thing is to apply a varnish, or lacquer, in all the little lines and cavities, and to stop and amend any little faults with shell gold.

The composition here called *vermilion*, is made of gum gutta, vermilion, and a little of some ruddy brown colour, ground together, with Venice varnish, and oil of turpentine. Some *gilders*, in lieu thereof, content themselves with fine laces, or diagen's blood, with gum-water.

Sometimes, instead of burnishing the gold, they burnish the ground or composition laid on last before it; and content themselves afterwards to wash the part over with size. The method is chiefly practised for the hands, face, and other rudiments in the relief; which, by this means, do not appear so very brilliant as the parts burnished; though much more so than the parts perfectly flat, or matted.

To gild a work, and yet preserve white grounds, they use to apply a layer of Spanish white, mixed with a weak fish-glass, on all the parts of the ground whereon the yellow, or the layer next under the gold, might run.

GILDING, JAPANESE, is performed by means of gold powder, or imitations of it, cemented to the ground by a kind of gold leaf for the method of preparing which, see *GOLD-FACE*.

This kind of *gilding* may be practised on almost any substance whatever, whether wood, metal, leather, or paper; not in those any preparation necessary, besides making the surface on which the size is to be laid, even and perfectly clean. When spread the Japanese size, mixed with a due proportion of oil of turpentine and vermilion, with a brush over the work, if the whole surface is to be gilt; or draw with it, by means of a pencil, the proper figure desired, avoiding carefully any other parts: when it is almost dry, so as to be capable, by its clamminess, of receiving the gold, dip a piece of wash-leather, wrapped round the finger, in the gold powder, described under *FINE GOLD*, and rub it lightly over the sized work; or spread the powder with a soft camel's hair pencil; and with a camel's hair-brush clear away the loose powder, after the gilded surface is dry. When last gold is used, the method of sizing must be the same as for the powders; but great care is necessary in laying them on, while the size is in a proper state of dryness.

There is a *false kind of gilding*, in which a colour of gold is given by painting and varnishes, without employing gold. Thus a very fine golden colour is given to brass, and to silver, by applying on these metals a gold-coloured varnish, which, being transparent, shows all the brilliancy of the metals underneath. Many ornaments of brass are varnished in this manner, which is called *gold lacquering*, to distinguish them from those that are really gilt. Silver leaves, thus varnished, are put upon leather, which is then called gilt leather; and many picture frames have no other than this counterfeit *gilding*, which may be discovered, by washing it with a little rectified spirit of wine: for the spirit will dissolve the varnish, and leave the silver leaf of its own whiteness. For plain picture frames, thin tin-foil may be used instead of silver; the tin-leaf, fixed on with glue, is to be burnished, then polished with emery, and a fine linen cloth, and afterwards with pumice, applied to the same manner; being then lacquered over with the varnish five or six times, it looks like burnished gold. See *LACQUERING*. Among the *false gildings* may also be reckoned those which are made with thin leaves of copper or brass, called Dutch leaf. In this manner are made all the kinds of what is called gilt paper. See *GILDING OF PAPER*.

GILDING OF LEAD. See *BOOK-BINDING*, and *GILDING OF PAPER*.

GILDING ON CHINA-WARE. The gold is very much valued on china-ware, and would be much more so were it not that it is very liable to lose its lustre, and to rub off. The Chinese, at present, have a method of preventing both these accidents, in a great measure, by means of a sort of polishing, which they give it, after it is laid on. They prepare for this purpose, a fine piece of agate, which they polish on one surface in as perfect a manner as possible. With this they rub over the gold as it lies on the porcelain several times, when it first comes from the baking. This gives the gold a lustre which it would not otherwise have, and fixes it down to the ware in such a manner that it cannot easily be got off. The principal mischief that gold, thus laid on, is subject to, is the tarnishing, or growing dull; this is remedied by the same sort of means. They use the vessel upon which they would revive the lustre of the gold, in common clear water; and while it is wet, they rub it with the same polished agate, adding a little fair water it takes to keep it moist. If the gold has not been well laid on at first, this may possibly raise it, or take it off in some places; but if it was originally put on with the help of this stone, as all the gold on porcelain now is, the rubbing it with it a second time never gives it any scratches, but recovers its primitive lustre and beauty. It must be observed that the rubbing with this stone must be all done one way, both in the first laying

on the gold, and in the brightening of it up afterwards. This may serve as a method for us as well as the Chinese, not only to recover the beauty of our tarnished gilt chinaware, but also to lay gold upon some of our home manufactures of this kind. Observe for Les Continues de l'Art. See PORCELAIN.

GILDING on enamel and glass is performed by burning, or annealing, i. e. by producing a cohesion of the gold with the glass or enamel, by the intermediation of a flux, or by producing the like effect without any. In both these methods, the gold is made to adhere to the enamel or glass, in consequence of the fusion or approach to that state, either of the flux used, or of the body of the enamel or glass itself, by which the gold is cemented to such body. The flux, when any is used, may be either simple glass of borax, or any of the preparations of FLUXES powdered; and the gold is used, either in the form of leaf gold, or in that of powder made mechanically, or by precipitation. See GOLD powder. When leaf gold is employed without any flux, the enamel or glass may be moistened with a very weak solution of gum arabic, and again dried. After being thus prepared, it should be breathed upon till it becomes a little adhesive or sticky, and then laid upon a sufficient number of leaves of gold; when the gold is thus united to the enamel or glass by the cementing quality of the gum arabic, the work is ready for burning. If a flux be used, it should be finely levigated, tempered with a very weak solution of gum arabic, and very thinly spread on the part of the work to be gilded; and when the gum water is almost dry, the leaf gold should be laid on the part thus prepared for it, which is then in a state proper for burning. In the present practice, the *aurum fulminans*, or precipitation of gold by alkaline salts, is made by those who gild glass in the greatest perfection; and the volatile alkali is employed for the precipitation by the chemist, who prepares it for this purpose. But when this kind of precipitate is chosen, the use of any flux must be avoided, and a very considerable degree of heat applied. The manner of using the precipitate powders of gold, the *aurum fulminans* excepted, as well as the leaf gold, may be varied, by adding to it or omitting any flux; but in what way however the powder is used, it is to be tempered with the oil of spike, and worked as the ENAMEL colours; and the quantity of flux, when any is used, may be a third of the weight of the gold. In cases where the glass is very hard, or where the opportunity of a strong heat cannot be conveniently obtained, the expedient of using a flux in the following manner may be adopted with great advantage. Grind glass of borax to a fine powder; and, having tempered it with oil of spike, lay it on the glass where the gilding is to be made; then burn the glass with a degree of heat, that will cause the borax to run; and when it is cold, apply the precipitate or leaf gold, and burn it again, as in other cases. After the work is burnt, if it is intended to be burnished, a proper lustre may be given to it, by rubbing the gilded part with a dog's tooth, or with a fine agate, or iron burnishers. Handmaid to the Arts, vol. ii. p. 374, &c. See Ruby GLASS.

Drinking glasses, with gilt edges, have been much admired in this country; the best of these are brought from Germany; those that are made in England, though equal in beauty to the foreign, being greatly inferior in the durability of the gilding. Dr. Lewis made several experiments with a view of discovering this art; from which he concludes, that the gold is cemented to them by means of an intervening matter, which will adhere to glass as not easily to be rubbed off. He tried mastic, and other resinous bodies rubbed warm on the glass, and several spirituous varnishes; but none of these were found to adhere sufficiently to the glass. He recommends to the trial of the artists in this way the hunderell varnishes; and glasses have been since prepared in England, probably on the principles which he has pointed out, with as durable gilding as those brought from Bohemia and Thuringia.

M. Zeigler, in a German translation of the Commercium Philosophico-Technicum, describes a varnish for this purpose, with the method of using it, which appeared from his experiments to be the best. This varnish is prepared by boiling fine transparent amber, reduced to powder, in a brass vessel, to the cover of which a valve is fixed, with as much drying oil as will just cover it; and by diluting the above solution with four or five times its quantity of oil of turpentine. This varnish may be made to dry sooner, and acquire greater firmness by grinding it with a little white lead, or rather with a mixture of white lead and masticum. It is to be applied very thin on the glass, and the gold leaf laid lightly on the varnished parts; when the varnish is thoroughly hardened, the gold may be burnished, by laying a piece of smooth paper between the tooth or steel burnisher, and the gold.

This gilding, M. Zeigler observes, is durable, and of a fine lustre. Com. Phil. Techn. p. 95, and 614.

GILDING of figures and letters on paper, and for the embellishments of manuscripts, is performed with leaf-gold, tempered with gum-water, or the characters may be drawn with a milky solution of gum ammoniacum made in water, and gold-leaf applied upon them when almost dry; or if all or any part of them is become quite dry, they may be again sufficiently moistened for receiving the gold by breathing on them. Letters raised from the surface of paper or parchment, in the manner of embossed work, such as are seen on ancient manuscripts, may be formed either by friction on a proper body with a solid piece of gold, or by leaf gold. The former method is practised by tempering pulverized crystal with strong gum-water, and with this paste forming the letters; when they are dry, they are rubbed with a piece of solid gold, as in polishing, and the letters will appear as if gilt with burnished gold. The letters are formed with an embossed figure, either of the separate letters, or of whole words, cut in steel; and each letter of these stamps, when they are used, is anointed evenly with a feather dip in oil. Then fill these concave letters with the above paste, and strike the stamps in a perpendicular direction on the paper or vellum, laid over some sheets of paper.

When the embossed letters are formed with leaf gold, the following, or a similar composition, must be used. Thicken beaten whites of eggs with as much vermilion as is necessary to give them the confidence of paper; use the stamps as before; and when the letters are dry, moisten them by a small pencil with strong gum-water; and when this is almost dry, cover the letters with leaf-gold, pressing it close to every part of them with cotton or soft leathers; after the gilding is dry, polish it with proper burnishers. Com. Phil. Techn. p. 64, and Handmaid to the Arts, p. 452, &c.

GILDING of fine silk, as straw-silk, carps, &c. may be performed without injuring the silk, by means of a cement, which Mr. Hooker, in his polithemous papers, directs to be prepared in the following manner: put some Burgundy pitch into a new earthen pot, and warm the vessel till it receives so much of the pitch as will fill round it; then strew some finely powdered amber over the pitch when growing cold; add a mixture of three pounds of linseed oil, and one of oil of turpentine; cover the vessel, and boil the contained ingredients over a gentle fire; grind the mixture as it is wanted, with so much pumice-stone as will reduce it to the consistence of paint. When the silk has been wiped dry, this mixture is spread upon it, and the gold leaf laid over it, and gently pressed down: after which, the silk may be immediately put into water, and the cement will harden, and be in no danger of falling off.

GILDING on leather. See LACQUERING.

GILDING of metals may be done by cleaning the surface of the metal, and applying gold leaves to it, which, by means of rubbing with a polished blood-stone, and a certain degree of heat, are made to adhere perfectly well. In this manner silver leaf is fixed and burnished upon brass, in making French plates; and sometimes also gold leaf is burnished upon copper and upon iron. Some metals, and particularly silver, may be gilt in the following manner: dip pieces of linen in the solution of gold by aqua regia, and then burn them to ashes; rub these ashes on the surface of the silver, well cleaned from any unctuous matter, with a wet linen rag, and the particles of gold contained in them will thus be applied to the silver, and adhere to it, without the application of heat, or intervention of any other body. Burnish the silver with a blood-stone, till it acquires the colour of gold. Most gilt ornaments on fans, snuff-boxes, and other toys of much show and little value, are nothing but silver gilt in this manner. See Method of GILDING metals by the fire.

GILDING on paper, parchment, and vellum. There are various methods used for this purpose, according to the several ends which the gilding is designed to answer. But for the most part size, properly so called, and gum-water, are used as the cements, and the powders are more generally employed than the leaf gold. See the three first articles in GILDING.

The gilding proper to be used with water-colours may be either with the leaf-gold or powder: the leaf-gold may be laid on the designed ground by means either of gum-water, or singlase size; observing, that the gum-water or size be of the weaker kind, and laid sparingly on the ground, and that proper time be allowed for it to be dry; and then the gold is applied to it, as in the articles above recited; and it may be polished, if necessary, by the dog's tooth, or other kind of burnisher. In gilding larger surfaces, it will be found useful to colour the ground with the gall-stone; and when colours are to be laid on the

gilding, the gill of any beast brushed over the gold will adapt it for receiving the colour. When the gold powders are used along with paintings in water-colours, they are previously formed into *gildings*. The *gilding* proper for the coloured paper used in binding books, and for other such purposes, is performed much in the same manner; only, that the gum water and size may be much stronger, and that they are generally conveyed to the ground by means of a wooden plate or point, or by an engraved roller, which make an impression of the intended figure or design. In this kind of *gilding*, the japanner's gold-fine may be also commodiously employed, and this should be always used when the embossed appearance is wanted in the greatest degree; and for this purpose it should be thickened with yellow ochre, mixed with as much red lead as the proper working of the paint will admit. Instead of the genuine leaf-gold, or sold powder, the German powder, formed of the leaves called Dutch gold, is commonly used in this kind of *gilding*. The edges of books or paper are gilt in the manner directed under the article *Book-binding*. The cement to be used for this purpose may be strong gum-water, fine glass size, or glass size, or if glass melted, with the addition of some common proof spirit of wine, and a fifth part of honey or sugar-candy, to which should be added a third part of bole armenic. Or the following composition may be used: mix equal parts of bole armenic and sugar-candy, well powdered, with the whites of eggs beaten to an oily consistence.

GILDING on thread and wire. See *GOLD-thread*, and *GOLD-wire*.

GILDING on wood. See the three first articles in *GILDING*.

Method of GILDING metals, or of gilding by the fire. There are two ways of *gilding* by fire; viz. that with liquid gold, and that with leaf-gold.

The first is performed with gold amalgamated with mercury, in the proportion of about six or eight parts of mercury to one of gold.

In order to this operation, they heat a crucible red-hot, then put the gold and mercury in it, and stir them gently about, till the gold be found melted and incorporated into a mass with the mercury. See *AMALGAMATION of gold*. They then cleanse it by grinding it in a glass, stone, or wooden mortar, with some common salt and water, and occasionally renewing the water, till the amalgam ceases to discolour it, and appears of a pure vivid brightness. From the mass they separate the mercury not united therewith, by squeezing it between the fingers through a piece of flannel thin, or a linen cloth. To prepare the metal to receive this amalgam, they scrub it with a wire-brush, and wet it with water or beer, continuing to rub and wet it till all the foulness which might hinder the effect, upon all the metals be removed; which done, to quicken the work farther, they rub a mixture of quicksilver and aqua fortis over it, the aqua fortis serving not only to cleanse the surface of the metal from any rust or tarnish it may have acquired, but also to facilitate the application of the amalgam to its surface, by dissolving part of the mercury of the amalgam; and besides, when this solution is applied to the copper, this latter metal having a stronger disposition to unite with the nitreous acid than the mercury has, precipitates the mercury upon its surface.

They proceed now to apply the amalgam of gold, in order to which they use a little knife, or a brush made of brass wire for the purpose; with which they spread or overlay the whole work, as evenly as may be, being careful to mix no part. Then giving the work a gentle heat before the fire, with the hair-brush they dab and spread the amalgam farther and cover on it.

Thus far advanced, the metal is set over the fire, upon a grate, or in a sort of cage, under which is a pan of charcoal, yielding a heat just sufficient for evaporating the mercury; by which means the mercury is raised in fumes, and leaves the gold alone adhering to the work; in proportion as the mercury, evaporating and flying off, discovers places where gold is wanting, they take care to supply them, by adding new pieces of amalgam with the knife or brush.

If a thicker rub than is required than can result from so much of the amalgam as is applied at once, the metal, after the first quantity has left its gold fixed on the surface, is rubbed again with the mixture of mercury and aqua fortis, and more of the amalgam spread upon it. After the evaporation of the mercury from this, another quantity may be applied in the same manner. When the mercury is evaporated, so that the surface becomes uniformly of a pale yellow colour, the metal is made to undergo other operations, by which its colour and lustre are heightened. For this purpose, it is first rubbed with a scratch brush, composed of fine brass wire, till its sur-

face is made clean and smooth; then it is covered over with a composition called *gilding wax*, and again exposed to the fire till the wax be burnt off; and this application is repeated till the gold appears of a proper colour. This *gilding wax* is composed of bees-wax, mixed with some of the following substances, viz. red ochre, verdigris, copper scales, alum, vitriol, and borax. Thus the colour of the *gilding* is heightened by a perfect dissolution of some mercury remaining after the former operation. The gilt surface is then covered over with a fine fine composition, consisting of equal quantities of nitre, in ammoniac, green vitriol, and verdigris, finely powdered, and mixed up into a paste with water or urine. The piece of metal thus covered is heated till the mixture is broken, and quenched in water or urine. This effect seems to be produced by the acid of urine, which is decomposed by the vitriolic acid of the nitre, or other vitriolic salt, during the exposure to heat, acting upon any particles of copper which may happen to be on the gilded surface. Some artists think they give an additional lustre to their gilt work, by rubbing it with a liquor prepared by boiling some yellow materials, as saffron, opium, or turmeric. The only advantage of this operation is, that a part of the yellow matter remains in some of the hollows of the carved work, in which the *gilding* is apt to be more imperfect, and to which it gives a rich and solid appearance.

This method of *gilding* by amalgamation is chiefly used for *gilding* copper, or rather copper mixed with a few parts of brass, thus forming a composition of copper and zinc, which more readily receives the amalgam, and yields a colour more resembling that of gold than three-fourths of copper.

Iron cannot be gilt by amalgamation, unless it be provisionally coated with copper, by dipping it in a solution of blue vitriol, or rubbed with the vitriol till a little mottled. Iron may also receive a golden coat from a saturated solution of gold in aqua regia, mixed with spirit of wine; because the iron, having a greater affinity with the acid, precipitates the gold from it. But the method commonly used of fixing gold upon iron is that mentioned in the next article.

GILDING by the fire with gold leaves. To prepare the metal for this *gilding*, it must be first well scratched, or raked, then polished with a pumice-stone, and thus left to the fire to blue, i. e. to heat, till it appear of a blue colour. This done, the first lay of gold is clamped thereon, and lightly rubbed down with a pumice-stone, and thus exposed to a gentle fire.

They usually only give it three such lays, or four at most, each lay consisting of a single leaf for the common work, and of two for the extraordinary ones; so that each lay they set it afire to the fire. After the last lay, the gold is in a condition to be finished.

Another method is mentioned by authors of *gilding* upon metals, and also upon cardinals and plants, which is, to fuse gold with regulus of antimony, to pulverize this mass, and spread the powder upon the piece to be gilt; afterwards to expose it to such a fire that the regulus may be evaporated while the gold remains fixed. But Dr. Lewis mentions the following inconveniences to which this method is subject: the powder does not adhere to the piece, and cannot be equally spread; part of the gold is dissipated along with the regulus, which is fusible with the heat necessary for the evaporation of regulus of antimony; and copper is liable to be corroded by the regulus, and to have its surface rendered uneven. See *Phil. Trans. Com. Phil. Tech. p. 77, No. p. 49, 1757, 1758, 1759, Martener's Dict. Chem. Eng. edit. 1777, art. GILDING*.

GILDING on glass. See *CURTAINS*.

GILDING on iron. A slip of the hollow diamond cane, cut up to a smooth and sharp edge, with a good piece of leather this cane knife cuts the gold leaf better than any one of steel, as it is apt to stick to this last.

GILDING on paper. A flat piece of wood, about three inches long, and an inch broad, covered with a piece of fine woollen cloth.

By breathing upon this paper, to moisten the cloth a little, and then clapping it gently down upon the gold leaf, this may be raised from the cushion, and conveyed to the work to be gilded.

GILDING on stone. See *GILDING of Metals*.

GILLAD, Latin of. See *BAISAM*.

GILGAN, Latin of. See *DRACONARIUM*, in *Botan.* See *DRACONARIUM*.

GILGUL, Hebrew of. A Hebrew phrase, literally signifying the *rolling of a wheel*. To conceive the use of this expression it is to be observed, that the Jews have a tradition that, at the coming of the Messiah, no creature shall rise any-where but in the Holy Land. What, then, shall become of all the faithful interred in other parts? Shall they perish, and remain in the state of death?

No, say the Jewish doctors; but God will dig them subterraneous canals, or cavities, through which they shall roll, from their tombs to the Holy Land; and, when they are arrived there, God will blow on them, and raise them again.

The imaginary passage of the exiles, or others, of the Jews, from their tombs to the Holy Land, by rolling underground, is what they call *gigil hammichin*, the rolling of the dead.

GILL. See GROUTING.

GILLA, in *Chemistry and Pharmacy*, is an Arabic term for salt, peculiarly used among us for the emetic salt of vitriol.

This salt is prepared from that mineral, by three or four repeated operations: viz. dissolution, in May dew, filtration, and crystallisation. In defect of May dew, rain-water may serve.

Gilla is used in tertians, and all fevers arising from a corruption of humours, in the first passages. It destroys worms, and prevents putrefaction. The dose is from twenty grains to half a drachm, taken in broth, or in cordial waters.

GILBARCO, *veat.* See TACOT.

GILLS, *framing in Natural History*, those membranous cartilaginous parts in fishes, whereby they respire.

What we call *gills*, in fishes, serve the purpose of lungs; respiration of air is as necessary to fishes as to terrestrial animals: there is always a quantity of air inclosed among water; and it is this air that fishes respire. The whole mechanism of their *gills* is contrived with this view: viz. to separate, and imbibe this air, from the water, and present it to the blood, after the same manner as it is presented to the lungs of other animals. All fish, therefore, have these *gills*, except the eel, and the petromyzon.

M. Du Verney has unravelled this infinitely complicated piece of mechanism, in the *gill* of a carp: the first thing that offers is a fabric, consisting of a great number of bony laminae, each subdivided into an infinity of bony fibres, whose office is, to sustain the innumerable ramifications of an artery dispatched thither from the heart: the use of these ramifications is, to present the blood, extremely subdivided, and as it were, each globule of blood by itself, to the water. Between these laminae, and throughout the whole texture of the *gills*, are an infinite number of very narrow passages, destined to receive and imbibe the water which the fish takes in by the mouth, into little pores. In this state the air, its prison-doors being now in some measure opened, makes its escape, and joins itself to the blood of all the little arteries.

The *gill* has necessarily an alternate motion of dilation and compression, which is effected by another very curious piece of mechanism; when they dilate, the water is taken in; and when they contract, it is expelled again. Hence it is probable, that it is in the very instant of contraction, that the air expelled from the water is forced to enter the pores of the little blood-vessels, because the force is then greater than at any other time; and this action requires a considerable force. The same reason holds with respect to the lungs of men: accordingly, M. du Verney maintains, that though the air enter the lungs in the time of inspiration, it is only received into the blood in that of expiration, when the superfluous air is carried off by the trachea; so that the real inspiration, i. e. the entrance of the air into the blood, should be the expiration.

The water is taken in by the mouth, and carried off again, freed of its air, by the *gills*; and the air gained from it, is distributed, first to the arteries of the *gills* and thence, by the law of circulation, to all the little veins in the fish.

The *gill* in all fish is eight in number, four being placed on each side the throat. The lowest *gill* is always much smaller than either of the others; the other three on each side are gradually larger to the upper one, which is in all fish the largest.

Every one of these *gills* is composed of a bony substance formed into a semicircle, in most kinds, or bent into the shape of a bow. On the convex side of which there is formed a sort of flange, or the resemblance of a leaf.

Each leaf is of a size that it is composed of a double row of bony laminae, furnished like to many fishes; and each of these laminae is fixed to the convex part of the bow, by means of the membrane with which that bow is covered. These laminae have one part convex, and the other concave. The convex side is covered with numerous bony or cartilaginous teeth, and these are longest near the base, and become more and more short, as they are less hairy on the concave side; the hairs being shorter, and continued only to the middle of the laminae, not running all the way along it. These hairs are all the way connected

to the *gill* by a very tender membranous substance which covers the laminae, but they are each fixed at the base. Arted, Ichthyology.

The concave part of every lamina is applied to the convex part of the next opposite lamina, and the laminae are all connected one with another, by means of a membrane which arises at their base, and is continued by half their length; at this part the membrane becomes stronger, and forms a sort of cord. The rest of the lamina is free, and terminates in an extremely fine and flexible point. Every one of these laminae is invested with a fine and thin membrane, and each serves to receive the ramifications of the vessels which are brought into the branchiae. The inside of every bow or bony femicle which makes one *gill*, gives place to one artery, one vein, and one nerve. The conformation of this hollow part of each *gill* is different in different fish: in some it contains a number of smooth tubercles, which are short, and scarce stand out beyond the surface: this is the case in the *gill* of the eel, the eel, &c. In some it is in this manner beset with very rough tubercles, as in the cod; in some other, these tubercles are rough, and reflexible teeth, as in the fishbone, &c. In some also the surface, instead of tubercles, is beset with a sort of long hairs resembling rays, as in the carp; and finally, in some this part is beset with real, but short prickles, as in the chace. The use of the *gill* in fish seems to be to receive the blood which is produced from the heart into the air, and draw it to the small parts of the lamina, from whence it is returned by veins which discharge it to every part of the body, and to serve for the office of respiration. The motion of the *gill* of fish is no way so beautifully seen as in the viewing those of a small eel with a microscope. Two rows of these are always bended towards one against the other, while their ends play against one another, touching and going back again very regularly and successively, and imitating the opening and shutting of a pair of bellows, in a regular succession; and, in the generality of fish, one pair does this, while another pair only continues advanced, so as to close with their base, and this is done alternately by one and another pair all the time that the observation is continued. Phil. Trans. N° 225.

GILLS, *officers of the*. See FRANCHIA.

GILLS, *leaf of the*. See VALVULI FRANCHIA.

GILLY-flower, or JULY-flower. See PINK.

GILLY-flower, *quatre*. See DANDY-VIOLET.

GILLY-flower, *stock*. See STOCK Gilly-flower.

GILT-head, *Latin*, in *Ichthyology*, the name of a broad and flat fish, not unlike the bream in shape. It sometimes grows to eight or ten pounds weight; its scales are moderately large, its back is of a blackish green, and its sides of a dusky brown, with a faint cast of yellow. At the upper angle of the covering of the *gill* it has usually a black spot, and under that often a purple one, between its eyes. It has a fine gold-coloured arch, or lateral mark, the convex or gibbous part of which is toward the mouth, the points toward the eyes, and therefore, in the Linnæan system, it is the *SPARUS latus arcus lateralis*. The dorsal fin extends almost the whole length of the back, and consists of twenty four rays, the eleven first spiny, the others soft; the pectoral fin consists of seventeen soft rays; the ventral of six rays, the first of which is very strong and spiny; the anal fin of fourteen, the three first spiny; and the tail is much forked. The gill-plates of this fish are flat and broad, like those of certain quadrupeds; bones which they have certain bones in the lower part of the mouth, which assist in grinding their food.

It is common in the markets of Rome, Venice, &c. and caught in great plenty in the summer months in different parts of the Mediterranean; in winter it is more scarce, but more valued. Some have conquered this fish with the sea-bream or *SPARUS pagrus* of LINNÆUS. See PAGRUS.

GIMBOLS, denote the brass-rings by which a sea-compass is suspended in its box that usually stands in the *STOWACE*.

GIMBLETTING, in Sea-language, is applied to the anchor, to denote the action of turning it round by the stock, so that the motion of the hook appears similar to that of the handle of a gubbin, when it is employed to turn the wheel.

GIMMER-lark, or GAMMER-lark, a term used for the female of ewe lamb.

GIN, in *Artillery and Mechanics*, is a machine for raising great weights, composed of three long legs, two of which are kept at a proper distance by means of two iron or wooden bars fixed to one of the legs by means of a bolt at one end, and by the other end to the other leg with a bolt and key, so that it may be put on or off at pleasure. At three feet from the bottom is a roller moving in chocks, that are fastened to these poles by two iron bands and two iron bells. The three legs of this machine are joined together

gilder, the gill of any beast brushed over the gold will adapt it for receiving the colours. When the gold powders are used along with paintings in water-colours, they are previously formed into *gilt-gold*. The *gilding* proper for the coloured paper used in binding books, and for other such purposes, is performed much in the same manner; only, that the pure water and size may be much stronger, and that they are generally conveyed to the ground by means of a wooden plate or print, or by an engraved roller, which make an impression of the intended figure or design. In this kind of *gilding*, the japanners gold-size may be also commodiously employed, and this should be always used when the embossed appearance is wanted in the greatest degree; and for this purpose it should be thickened with yellow ochre, mixed with as much red lead as the proper working of the print will admit. Instead of the genuine leaf-gold, or gold powder, the German powder, formed of the leaves called Dutch gold, is commonly used in this kind of *gilding*. The edges of books or paper are gilt in the manner described under the article *book-binding*. The cement to be used for this purpose may be strong gum-water, linseed oil, or glassy size; or (if glass is melted), with the addition of some common good spirit of wine, and a small part of honey or sugar-syrup, to which should be added a third part of bole armoniac. Or the following composition may be used: mix equal parts of bole armoniac and hypericancy, well powdered, with the whites of eggs beaten to an oily confidence.

GILDING on thread and wire. See **GOLD-thread**, and **GOLD-wire**.

GILDING on wood. See the three first articles in **GILDING**.

Method of GILDING metals, or of gilding by the fire. There are two ways of *gilding* by fire; viz. that with liquid gold, and that with leaf-gold.

The first is performed with gold amalgamated with mercury, in the proportion of about six or eight parts of mercury to one of gold.

In order to this operation, they heat a crucible red-hot, then put the gold and mercury in it, and stir them gently about, till the gold be found melted and incorporated into a mass with the mercury. See **AMALGAMATION of gold**. They then cleanse it by grinding it in a glass, stone, or wooden mortar, with some common salt and water, and occasionally renewing the water, till the amalgam ceases to discolour it, and appears of a pure vivid brightness. From the mass they separate the mercury not united therewith, by squeezing it between the fingers through a piece of flannel, or a linen cloth. To prepare the metal to receive this amalgam, they scrub it with a wire-brush, and wet it with water or beer; continuing to rub and wet it till all the foulness which might hinder the close union of the metals be removed; which does, to quicken the work farther, they rub a mixture of quicksilver and aqua regia over it: the aqua regia being not only to cleanse the surface of the metal from any rust or tarnish it may have acquired, but also to facilitate the application of the amalgam to its surface, by dissolving part of the mercury of the amalgam; and besides, when this solution is applied to the copper, this latter metal having a stronger disposition to unite with the nitrous acid than the mercury has, precipitates the mercury upon its surface.

They proceed now to apply the amalgam of gold, in order to which they use a little knife, or a brush made of bristles wire for the purpose; with which they spread or evenly the whole work, as evenly as may be, being careful to mix no part. Then giving the work a gentle heat before the fire, with the hair-brush they dab and spread the amalgam farther and evener on it.

Thus far advanced, the metal is set over the fire, upon a grate, or in a sort of cage, under which is a pan of charcoal, yielding a heat just sufficient for evaporating the mercury; by which means the mercury is raised in fumes, and leaves the gold alone adhering to the work: in proportion as the mercury evaporates and flying off, discovers places where gold is wanting, they take care to supply them, by adding new pieces of amalgam with the hair or brush.

If a thicker *gilding* be required than can result from so much of the amalgam as is applied at once, the metal, after the first quantity has left its gold fixed on the surface, is rubbed all over with the mixture of mercury and aqua regia, and more of the amalgam spread upon it. After the evaporation of the mercury from this, another quantity may be applied in the same manner. When this mercury is evaporated, and the surface becomes uniformly of a pale yellow colour, the metal is made to undergo other operations, by which its colour and lustre are heightened. For this purpose, it is first rubbed with a scratch brush, composed of fine hair wire, till its sur-

face is made clean and smooth; then it is covered over with a composition called *gilding wax*, and again exposed to the fire till the wax be burnt off; and this application is repeated till the gold appears of a proper colour. This *gilding wax* is composed of bees wax, mixed with some of the following substances; viz. red ochre, verdigris, copper scales, alum, vitriol, and borax. Thus the colour of the *gilding* is heightened by a perfect distillation of some mercury remaining after the former operation. The gilt surface is then covered over with a fine composition, consisting of equal quantities of nitre, sal ammoniac, green vitriol, and verdigris, finely powdered, and mixed up into a paste with water or urine. The piece of metal thus covered is heated till the mixture fumes, and quenched in water or urine. This effect seems to be produced by the acid of nitre, which is dissipated by the vitriolic acid of the alum, or other vitriolic salt, during the exposure to heat, acting upon any particles of copper which may happen to lie on the gilded surface. Some artists think they give an additional lustre to their gilt work, by adding to it a liquor prepared by boiling some yellow materials, in volatility, argemone, or turmeric. The only advantage of this operation is, that a part of the yellow matter remains in some of the hollows of the carved work, in which the *gilding* is apt to be more imperfect, and to which it gives a rich and solid appearance.

This method of *gilding* by amalgamation is closely used for *gilding* copper, or rather copper mixed with a few other parts of brass, thus forming a composition of copper and zinc, which more readily receives the amalgam, and yields a colour more resembling that of gold than the colour of copper.

Iron cannot be gilt by amalgamation, unless it be previously coated with copper, by dipping it in a solution of blue vitriol, or rubbed with the vitriol itself a little mended. Iron may also receive a golden veil from a saturated solution of gold in aqua regia, mixed with spirit of wine; because the iron, having a greater affinity with the acid, precipitates the gold from it. But the method commonly used of fixing gold upon iron is that mentioned in the next article.

GILDING by the fire with gilt leaves. To prepare the metal for this *gilding*, it must be first well fractured, or raked, then polished with a pollinary, and thus left to the fire to blue, i. e. to heat, till it appear of a blue colour. This done, the first lay of gold is clapped thereon, and lightly rubbed down with a pollinary; and thus exposed to a gentle fire.

They usually only give it three such lays, or four at most, each lay consisting of a single leaf for the common works, and of two for the extraordinary ones; after each lay they let it settle to the fire. After the last lay, the gold is in a condition to be burnished.

Another method is mentioned by authors of *gilding* upon metals, and also upon earthenware and glass; which is, to fore-paint with red oxide of antimony, to prepare this mass, and spread the powder upon the piece to be gilt, afterwards to expose it to such a heat that the red oxide may be evaporated while the gold remains fixed. But Dr. Lewis mentions the following inconveniences to which this method is subject: the powder does not adhere to the piece, and cannot be equally fixed; part of the gold is dissipated along with the vapours; gold is scarce with the heat necessary for the evaporation of red oxide of antimony; and copper is liable to be corroded by the red oxide, and to have its surface rendered uneven. Lewis's Com. Phil. Techn. p. 77, &c. p. 82, 231. See **1788**. Masquer's Dict. Chem. Eng. edit. 1777. art. **GILDING**.

GILDING-cupids. See **CRAFTSMAN**.

GILDING-knife. A dip of the hollow Spanish cane, cut up to a smooth and sharp edge, with a good pen-knife this cane knife cuts the gold leaf better than one of steel, as it is apt to flick in due fall.

GILDING-pallet. A flat piece of wood, about three inches long, and an inch broad, covered with a piece of fine woollen cloth.

By breathing upon this pallet, to moisten the cloth effectually, and then clapping it gently down upon the gold leaf, this may be raised from the cushion, and conveyed to the work to be gilded.

GILDING-horn. See **GILDING of metals**.

GILLAD. *Latin* *g.* See **BALAN**.

GILLAD. *Latin* *g.* *Dracophaena*, in *Batani*. See **MACADON**.

GILGUL *Hebrew*, a Hicton phrase, literally signifying the raising of the dead. To conceive the idea of this resurrection it is to be observed, that the Jews have a tradition that, at the coming of the Messiah, no living shall die any-where but in the Holy Land. What, then, shall become of all the faithful interred in other parts? shall they perish, and remain in the state of death?

No, say the Jewish doctors; but God will dig them subterranean canals, or cavities, through which they shall roll from their tombs to the Holy Land; and, when they are arrived there, God will blow on them, and raise them again.

This imaginary passage of the carcasses, or ashes, of the Jews, from their tombs to the Holy Land, by rolling underground, is what they call *gilgul hametzah*, the rolling of the dead.

GILL. See GROUND-IVY.

GILLS, in *Chemistry and Pharmacy*, is an Arabic term for salt, peculiarly used among us for the emetic salt of vitriol.

This salt is prepared from that mineral, by three or four repeated operations; viz. dissolution, in May-dew; filtration, and crystallization. In defect of May-dew, rain-water may serve.

Gills is used in various, and all fivers arising from a corruption of humours, in the first passages. It dissolves worms, and prevails purgation. The dose is from twenty grains to half a drachm, taken in broth, or in cordial waters.

GILLARDO, trout. See TROUT.

GILLS, described in *Natural History*, those membranous cartilaginous parts in fishes, whereby they respire.

What we call *gills* in fishes, serve the purposes of lungs; respiration of air is as necessary to fishes as to terrestrial animals: there is always a quantity of air enclosed among water; and it is this air that fishes respire. The whole mechanism of their *gills* is contrived with this view; viz. to separate, and imbibe this air, from the water, and present it to the blood, after the same manner as it is presented to the lungs of other animals. All fish, therefore, have these *gills*, except the cartaceous and petromyzon.

M. Du Verney has unravelled this infinitely complicated piece of mechanism, in the *gill* of a carp; the first thing that offers is a fabric, consisting of a great number of bony laminae, each subdivided into an infinity of bony fibres, whose office is, to sustain the innumerable ramifications of an artery dispatched thither from the heart: the use of their ramifications is, to present the blood, extremely subdivided, and, as it were, each globule of blood by itself, to the water. Between these laminae, and throughout the whole texture of the *gills*, are an infinite number of very narrow passages, destined to receive and subdivide the water which the fish takes in by the mouth, into little parcels. In this state the air, its prison-doors being now in some measure opened, makes its escape, and joins itself to the blood of all the little arteries.

The *gills* have necessarily an alternate motion of dilatation and contraction, which is effected by another very curious piece of mechanism; when they dilate, the water is taken in; and when they contract, it is expelled again. Hence it is probable, that it is in the very instant of contraction, that the air, expelled from the water is forced to enter the pores of the little blood-vessels, because the force is then greater than at any other time; and this action results a considerable force. The same reason holds with respect to the lungs of men; accordingly, M. Du Verney maintains, that though the air enters the lungs in the time of inspiration, it is only received into the blood in that of expiration, when the superfluous air is carried off by the trachea; so that the real inspiration, i. e. the entrance of the air into the blood, should be the expiration.

The water is taken in by the mouth, and carried off again, freed of its air, by the *gills*; and the air gained from it, is distributed, first to the arborescence of the *gills*; and thence, by the law of circulation, to all the little veins insinuated therewith.

The *gills* in all fish are eight in number, four being placed on each side the throat. The lowest *gill* is always much smaller than either of the others; the other three on each side are gradually larger to the upper one, which is in all fish the largest. Every one of these *gills* is composed of a bony substance formed into a femicircle, in most kinds, or bent into the shape of a bow. On the convex side of which there is formed a sort of plume, or the resemblance of a leaf.

Each leaf (so to speak) is composed of a double row of bony lamellae, formed like to many fickers, and each of these lamellae is fixed to the convex part of the bow, by means of its membrane, with which this bow is covered. These lamellae have one part convex, and the other concave. The convex side is covered with numerous bristles in all parts, and these are longest near the base, and become toward the apex. They are less hairy on the concave side; the bristles there being shorter, and continued only to the middle of the lamellae, not running all the way along it. These hairs are all the way connected

to the *gill* by a very tender membranous substance, which covers the lamellae, but they are each single at the base. Arted, Ichthyology.

The concave part of every lamina is applied to the concave part of the next opposite lamina, and the laminae are all connected one with another, by means of a membrane which arises at their base, and is continued by half their length; at this part the membrane becomes thinner, and forms a sort of cord. The rest of the lamina is free, and terminates in an extremely fine and flexible point. Every one of these laminae is invested with a fine and thin membrane, and each serves to receive the ramifications of the vessels which are brought into the branchings. The table of every bow or bony femicircle which makes one *gill*, gives place to one artery, one vein, and one nerve. The conformation of this hollow part of each *gill* is different in different fish; in some it contains a number of tooth tubercles, which are short, and scarce stand out beyond the surface; in the case in the *gill* of the eel, the eel, &c. In some it is in this manner bristled with very rough tubercles, as in the cod; in some others these tubercles are rough, and resemble teeth, as in the salmon, &c. In some also this surface, instead of tubercles, is strewed with a sort of long hairs resembling rats in the clasp; and finally, in some this part is bristled with real, but short prickles, as in the eel. The use of the *gill* in fish seems to be to receive the blood which is procured from the heart into the aorta, and drive it to the smooth parts of the lamina, from whence it is returned by veins which distribute it to every part of the body, and to serve for the office of respiration. The motion of the *gill* of fish is no way so beautifully seen as in the view of those of a small eel with a microscope. Two rows of these are always bended roundly one against the other, while their ends play against one another, touching and going back again very regularly and successively, and imitating the opening and shutting of a pair of bellows, in a regular succession; and, in the generality of fish, one pair does this, while another pair only continues advanced, it is as to close with their base, and this is done alternately by one and another pair all the time that the operation is continued. Phil. Trans. N° 252.

GILLS, aperture of the. See DIAPHRAGM.

GILLS, leaf of the. See FOLIUM FRANCHIERI.

GILLY-flower, or JULY-flower. See FLOX.

GILLY-flower, Jacob's. See DANIEL VIOLET.

GILLY-flower, black. See STOCK GILLY-flower.

GILT-head, Zucchi, in *Ichthyology*, the name of a broad and flat fish, not unlike the bream in shape. It sometimes grows to eight or ten pounds weight; its scales are moderately large, its back is of a blackish green, and its sides of a dusky brown, with a faint cast of yellow. At the upper angle of the coverings of the *gill* it has usually a black spot, and under that often a purple one between its eyes. It has a fine gold-coloured, arched, or limited mark, the convex or gibbous part of which is toward the mouth, the points toward the eyes; and, therefore, in the Linnæan system, it is the *SPARUS LAMIA aurea notus*. The dorsal fin extends almost the whole length of the back, and consists of twenty-four rays, the dorsal fin spines, the others, &c. the peduncle tail consist of fourteen soft rays; the ventral of six rays, the first of which is very strong and spiny; the anal of fourteen, the three last spiny; and the tail is much forked. The gill covers of this fish are flat and strong, like those of certain quadrupeds; besides which they have certain bones in the lower part of the mouth, which assist in grinding their food.

It is common in the markets of Rome, Venice, &c. and caught in great plenty in the summer months in different parts of the Mediterranean; in winter it is more scarce, but more valued. Some have confounded this fish with the sea-bream or *SPARUS pagrus* of Linnæus. See PAGES.

GIMBOLS, denote the brass-rings by which a sea-compass is suspended in its box that usually stands in the PINACLE.

GIMBLETTING, in Sea-language, is applied to the anchor, to denote the action of turning it round by the stock, so that the motion of the hook appears similar to that of the handle of a gimble, when it is employed to turn the wire.

GIMMER-lamb, or GAMMER-lamb, a term used for the female or ewe lamb.

GIN, in *Artillery and Mechanics*, is a machine for raising great weights, composed of three long legs, two of which are kept at a proper distance by means of two iron or wooden bars fixed to one of the legs by means of a bolt at one end, and by the other end in the other leg with a bolt and key, so that it may be put on or off at pleasure. At three feet from the bottom is a roller moving in checks, that are fastened to these poles by two iron bands and two iron bells. The three legs of this machine are joined to-
get

gether with an iron bolt, about which they move; to this bolt is fixed an iron half ring to hook on the wind-lash, containing two brass pulleys. When the gin stands upright, and its legs are at a proper distance, one end of the cable is fixed to the dolphins of a gun or mortar with another windlass, containing likewise two brass pulleys, and the other pulleys through the pulleys and round the roller, which is turned round by means of handspikes passing through the holes in the ends of the roller: while a man holds the cable tight, the gin is raised to such a height as to admit a carriage being put under it.

Gin, in *Diphilley*. See GUNEA.

GINETTA, or GINETTA, GEBET, the *VIVERRA genetta* of Linnaeus, the name of a small animal of the weasel-kind, of a tawny red colour, ornamented with several black spots in different parts of the body, and the ridge of the back marked with a black line. It is naturally a very tame and inoffensive creature. It is usually found about rivers, feeding on what it finds about their banks. It is found in some parts of Spain, and at Constantinople, and in some other parts of the Turkish dominions. It runs half about the houses like a cat, and is as useful in catching mice, in fact, which is long, is variegated with circles of black and tawny colours; its feet are black, its ears a little pointed, and its tail is of a somewhat perfumed flesh.

GINGER, *Zingiber*, in *Botany*, a genus of the *monocotyledonous* class. Its characters are these: the flowers are collected in a scaly spike, each having a double stamens; the flower is of one leaf, tubulose below, and divided into three parts at the brim. In the bottom of the flower is situated an oblong thick nectarium; from the tube of the flower arise two slender stamens, crowned with thick, short filaments. Under the receptacle of the flower is placed the round germ, supporting a single style as long as the tube of the flower, and crowned with a hairy stigma, which afterward becomes an oval three-cornered seed-vessel, opening in three parts, containing several seeds. There are three species.

The first, which is the common ginger, is cultivated for sale in most of the islands in America; but is a native of the East Indies, and also of some parts of the West Indies, where it is found growing naturally without culture. The dried roots of this form a considerable export from the British colonies in America.

The second sort grows naturally in India: the roots of this are much larger than those of the first, but are jointed in the same manner. The latter hath thick fleshy roots, resembling those of the large flag iris. These sorts are tender, and require a warm room to preserve them in this country.

They are propagated by sowing the roots; the best season for doing which is early in spring, before they begin to shoot. Every large part of the root may then be divided into several slips, with two or three eyes to each, all which will succeed: these are to be planted separately in pots of a light rich earth, and plunged into a hot-bed of tanners bark, where they must be sparingly watered, till their stalks appear above ground; afterward, during the summer months, more plentifully; but in autumn and winter less frequently; and in hot weather must often have the glasses raised with a brick to give them air. They will increase greatly at the root, and sometimes flower with us; but they must be kept to the hot-bed all the summer, and in winter be removed into the back-stove. Miller.

When arrived at maturity, they dig the root up, and dry it on handies, either in the sun or an oven: the best is that which is new, dry, well filled, hard to break, of a brownish colour without, refinous within, and of a hot, pungent taste.

They use to candy the root, when green, with sugar and honey; having first steeped it some time in water, to take away part of its acrimony, and to dispose it to let go the outer skin. They also make a marmalade of it, and dry cakes.

The northern people make great use of this confection, as holding it sovereign against the scurvy. The Indians eat the root, when green, by way of salad, first chopping it small, mixing it with other herbs, and seasoning it with oil and vinegar.

This warm aromatic root appears to be much less liable to heat the constitution than might be expected from the penetrating heat and pungency of its taste, and the fixeness of its active principles. It gives part of its virtue to water, and the whole to rectified spirit, tinging the latter of a deep, and the former of a pale yellow colour. In the shops is kept a syrup made from an infusion of three or four ounces of the root in three or four pints of boiling water, which is agreeably impregnated with its warmth and flavour; and the candied ginger, brought from abroad, which is likewise moderately aromatic. Lewis.

As to its medicinal use, it is hot and penetrating; it is also held good to strengthen the stomach, and promotes appetite: it promotes also digestion, prevents putrefaction, &c. and is an ingredient in many of the compositions, and powders of the shops.

Ginger may be preferred by washing it, and letting it to steep for ten or twelve days in white wine and water, stirring them every day; then boil a pound of roots with two quarts of white wine, and about a pint of lemon juice, for a quarter of an hour; then add two pounds and a half of fine sugar, and boil it to a syrup, foaming it as it rises; let it by till the next day in a glazed pan; then boil it for half an hour, and repeat this boiling at the same interval till the ginger is clear. Put it into glasses, and cover them with paper, and it will afford a fine sweet meat for the winter season.

GINGERBREAD, a richer kind of bread, the flavour and taste whereof are heightened, and improved with spices, and particularly ginger; whence the name.

There are various forms and preparations of gingerbread: we shall content ourselves with the following receipt, which is well recommended.

Into a pound of almonds, blanched and pounded, grate a penny white loaf; sift and beat them together; to the mixture add an ounce of ginger, scraped, fine, and liquorice, and mixed in powder, of each a quarter of an ounce; pour in two or three spoonfuls of rose-water, and make the whole into a paste, with half a pound of sugar; mould and roll it, print it, and dry it in a stove. Others make it of treacle, citron, lemon, and orange-peel; with candied ginger, coriander, and caraway-seeds, mixed up with as much flour as will make it into a paste.

GINGERBACHIUM, a name given by some medicinal authors to the scurvy, when it affects the arms and other extremities.

GINGIDIUM. See ARTEZIA.

This is also a term used by *Battani* for a species of FENNEL.

GINGIPEDIUM, a name given by some authors to the scurvy when it affects the feet.

GINGIVA, in *Anatomy*, the GUM; a hard sort of flesh, investing the alveoli, or sockets, of the teeth.

The gingivae are formed by the union of two membranes; one of which is a production of the periosteum, and the other of the internal membrane of the mouth.

GINGLYMUS, *Trochanter*, in *Anatomy*, one of the species of articulation.

The *ginglymus* is that jointure of the bones where each bone mutually receives the other; so that each bone both receives, and is received.

There are three species of *ginglymus*: the first, when the same bone, at the same extremity, receives, and is reciprocally received by another bone, after the manner of a hinge; such is that of the cubitus and humerus.

The second, when a bone receives another at one of its extremities; and is received into another, at the other; as the vertebrae do.

The third is that where a bone is received into another, after the manner of a wheel, or the axis of a wheel, in a box; such is that of the second vertebra of the neck in the first.

GINGRA, in *Antiquity*, a kind of dance used at funerals.

GINGRINA, in *Antiquity*, a name given to a small kind of flute fit for beginners.

GINORA, in *Botany*, a genus of the *dodecandria digyna* class; the characters of which are, that the calyx is divided into five segments; the number of petals six; and the fruit is a single celled, four-valved, coloured, plurisperous capsule.

GIN-SENG, or NIX-SENG, *Panax*, in *Botany*, a genus of the *polygama dicotyled* class. Its characters are these: it hath male and hermaphrodite flowers on distinct plants; the male have simple globular umbels, composed of several coloured rays, which are equal; the flower has five narrow, oblong, blunt petals, which are reflexed, fitting on the empanclement, and five oblong slender stamens inserted in the empanclement, terminated by single filaments; the hermaphrodite umbels are simple, equal, and clustered; the involucrum is small, permanent, and composed of several oval-shaped leaves; the flowers have five oblong equal petals, which are recurved, and five short stamens, terminated by single filaments, which fall off, with a roundish germ on the empanclement, supporting two small erect styles, crowned by single stigmas; the germ afterward becomes an unbelated berry with two cells, each containing a single, heart-shaped, convex, plain seed. There are two species, both of which grow naturally in North America; one of them is believed to be the same with the Turanian *panax*, the figures and description of that plant, which have been

sent to Europe by the missionaries, agreeing perfectly with the American plant.

This hath a fleshy taper root, as large as a man's finger, which is jointed, and frequently divided into two smaller fibres downward: the stalk rises above a foot high, naked to the top, where it generally divides into three smaller footstalks, each sustaining a leaf composed of five spear-shaped lobes, which are sawed on their edges; they are of a pale green and a little hairy: the flowers arise on a slender footstalk, just at the division of the footstalks which sustain the leaves, and are funnelled into a small tubel at the top: they are of a herbaceous yellow colour, composed of five small petals, and recurved: these appear the beginning of June, and are succeeded by compressed heart-shaped berries, which are fast green, but afterward turn red, including two hard, compressed, heart-shaped seeds, which ripen in the beginning of August. Miller.

The *gin-feng* is one of the principal medicines of the Chinese and Tartars, and their most eminent physicians have written many volumes concerning its virtues.

It is known among them by divers other names, expressing only spirit, or the pure spirit of the earth, the plant that grows immortally, &c. It makes, in effect, the whole materia medica for the people of condition, but is too precious for the populace.

All the writers of the Chinese affairs make mention of the *gin-feng*: as Martinus, in his Atlas; F. Kercher, in his China Illustrata; F. Tschard, in his Voyages; and F. Le Comte, in his Memoirs.

And yet we know but very little of this plant before F. Jatrova, a Jesuit, and missionary in China; who, being employed, by order of the emperor, in making a map of Tartary, in the year 1709, had an opportunity of seeing it growing in a village about four leagues from the kingdom of Corea, inhabited by Tartars, called *Caha-Tatars*.

That father took this opportunity to make a draught of the plant, and give an accurate description thereof, with its virtues and manner of preparing it; which, being a great curiosity, we shall here gratify the reader with.

The *gin-feng*, represented *Tah. Nat. Hist.* fig. 10, has a white root, somewhat knobby, about thrice the thickness of the stem, and which goes tapering to the end; at a few inches from the head it frequently parts into two branches, which gives it some resemblance of a man, whose thighs the branches represent: and it is hence it takes the denomination *gin-feng*, which signifies a figure of a man.

It is hard to say, why the Chinese should call it *gin-feng*, a word which signifies figure, or representation of a man: neither that father, nor any he enquired of, could ever find that it bore more resemblance to the figure of a man than is ordinarily from among other roots. The Tartars, with more reason, call it *erbat*, that is, the stiff of plants. It grows to the height of about eighteen inches.

The plant dies away every year: the number of its years may be known by the number of stalks it has shot forth, of which there always remains some mark, as is shewn in the figure by the letters *b b b*, &c. from whence it appears that the root *A* was seven years old.

Those who gather the *gin-feng* preserve only the root; and all they can get of it in ten or fifteen days time they bury together, in some place under ground; then they take care to wash it well, and scour it with a brush; then dip it in boiling water, and prepare it in the fumes of a sort of yellow millet, which gives it part of its colour. The millet is put in a vessel, with a little water, and boiled over a gentle fire: the roots are laid over the vessel, upon small transverse pieces of wood, being first covered with a linen cloth, or some other vessel placed over them.

They may also be dried in the sun, or by the fire; but then, though they retain their virtue well enough, they have not that yellow colour which the Chinese so much admire. When the roots are dried, they must be kept close in some very dry place; otherwise they are in danger of rotting, or of being eaten by worms. The method of curing *gin-feng* is described in the *Med. Transl.* vol. III. p. 35.

As to the place where this root grows, it is between the thirty-ninth and forty-fourth degree of both latitudes, and between the tenth and twentieth degree of east longitude, reckoning from the meridian of Peking. Here it is found a long tract of mountains, which thick forests, that cover and encompass them, render almost impassable: it is upon the declivities of these mountains, and in these thick forests, upon the banks of torrents, or about the roots of trees, and amidst a thousand other different sorts of plants, that the *gin-feng* is found; it is not to be met

within plains, valleys, marshes, the bottoms of rivulets, or in places too much exposed and open.

If the forest takes fire, and be consumed, this plant does not appear till two or three years after it also lies hid from the sun as much as possible, which shows that heat is an enemy to it.

The places where the *gin-feng* grows are, on every side, separated from the province of Canton by a barrier of wooden stakes, which encompasses this whole province, and about which guards continually patrol, to hinder the Chinese from going out and looking after this root. Yet, how vigilant, say they are, yet almost after gain incites the Chinese to look about privately in these deserts, sometimes to the number of two or three thousand, at the hazard of losing their liberty, and all the fruits of their labour, if they are taken either as they go out of, or come into the province.

The emperor, in order that the Tartars should reap all the advantage that is to be made of this plant rather than the Chinese, gave orders, in 1709, to ten thousand Tartars, to go and gather all they could find of the *gin-feng*, upon condition that each person should give him two ounces of the herb, and that the rest should be paid for, weight for weight, in pure silver.

It was computed, that, by this means, the emperor would get this year above twenty thousand Chinese pounds of it, which would not cost him above one fourth part of its value.

We met, by chance, says F. Jatrova, with some of these Tartars, in the midst of those frightful deserts, and their mandarin, who were not far out of the way, came, one after another, and offered us each for our subsistence, according to the commands they had received from the emperor.

This army of hermits observed the following order: after they had divided a certain tract of land among their several companies, each company, to the number of a hundred persons, spiced itself out in a right line, to a certain fixed place, every ten of them keeping at a distance from the rest.

Then they searched carefully for the plant, going on leisurely in the same order; and in this manner, in a certain number of days, they run over the whole space of ground appointed them.

When the time was expired, the mandarins, who were encamped in their tents in such places as were proper for the subsistence of their horses, sent to view each troop, to give them fresh orders, and to inform themselves if their number was complete.

If any one of them was wanting, as it often happened, either by wandering out of the way, or being attacked by wild beasts, they always looked for him a day or two, and then returned again to their labour as before.

The *gin-feng*, we have observed, is an ingredient in most of the medicines which the Chinese physicians prescribe to the better sort of patients: they affirm, that it is a sovereign remedy for all weaknesses occasioned by excessive fatigues, either of body or mind; that it attenuates and carries off pituitous humours; cures weakness of the lungs and the pleurisy; stops vomitings; strengthens the stomach, and helps the appetite; dissipates fumes or vapours; fortifies the breast; it is a remedy for short and weak breathing; strengthens the vital spirits, and is good against dizziness of the head and dimness of sight; and that it prolongs life to extreme old age. Nobody can imagine, that the Chinese and Tartars would set so high a value upon this root, if it did not constantly produce a good effect: those that are in health often make use of it to render themselves more vigorous and strong. And I am persuaded, says the father just mentioned, it would prove an excellent medicine in the hands of any European who understands pharmacy, if he had but a sufficient quantity of it to make such trials as are necessary to examine the nature of it chemically, and to apply it in a proper quantity, according to the nature of the disease for which it may be beneficial.

It is certain, that it subtilizes, increases the motion of and warms the blood, that it helps digestion, and invigorates in a very sensible manner.

After I had designed the root, he goes on, I observed the late of my yule, and then took half of a root, raw as it was, and unprepared, in an hour after I found my pulse much fuller and quicker; I had an appetite, and perceived myself much more vigorous, and could bear labour better and easier than before. Four days after, finding myself fatigued and weary, that I could scarce sit on my horse, a mandarin, who was in company with us, perceiving it, gave me one of these roots; I took half of it immediately, and an hour after I was not in the least sensible of any weakness. I have often made use of it since, and always with the same success. I have

have observed also, that the green leaves, and especially the fibrous part of them, chewed, would produce nearly the same effect. The Tartars often bring people the leaves of *ginseng* instead of tea; and I always find myself to well afterwards, than I should readily prefer them before the best tea: their decoction is of a grateful colour, and, when not has taken it twice or thrice, its taste and smell become very agreeable.

As for the root, it is necessary to boil it a little more than tea, to allow time for extracting its virtue, as is practised by the Chinese, when they give it to sick persons; on which occasion they seldom use more than the fifth part of an ounce of the dried root.

To prepare the root for exhibition they cut it into thin slices, and put it into an earthen pot well glazed, with about half a pint of water; the pot is to be well covered, and let to boil over a gentle fire; and, when the water is consumed to the quantity of a cup full, a little sugar is to be mixed with it, and to be drunk; immediately after this, as much more water is to be put to the remainder, and to be boiled as before, to extract all the juice, and what remains of the fibrous part of the root.

These two doses are to be taken, the one in the morning, and the other in the evening. Phil. Trans. N^o. 337. or Abstr. vol. ix. p. 344. &c.

The *ginseng* root, though far unequal to the character that has been commonly given it, promises, from its sensible qualities, to be an useful addition to the official drugs. To the taste it discovers a mucilaginous sweetness, approaching to that of liquorice, accompanied with some degree of bitterness, and a slight aromatic warmth, with little or no smell. The sweet matter of the *ginseng* is preserved entire in the waters, as well as in the spirituous extracts; and the slight aromatic impregnation is partly retained in the former, and perfectly in the latter, which still is a very pleasant, bitterish, warm sweet. Lewis.

GIOAR, in the *Matéria Medica* of the ancient Arabians, a word applied to several different substances, and sometimes used as the distinct names of them; sometimes only as an epithet to them. It is generally used by Avicenna as a name for arsenic, sometimes for antimony, and in Serapion, we often find it standing for any of the mineral poisons. The original meaning of the word is no more than what the Greeks expressed by the word *ars*, *sulfur*; but it became applied to several things most eminent in their way; as to arsenic, the most fatal of poisons; to antimony, supposed at that time the most valuable of medicines; and to pearls as the most valuable of gems.

GIOMELI, a body of the sphais, or horse, in the service of the grand signior.

GIR, a name by which some of the chemical writers have called quick-lime.

GIRAFEE, or *Camelopard*, in *Leop.* See *Tak. Quadruped.* fr. 7. and *CAMELOPARDA*.

GIRANDOLE, a large kind of branched candlestick. See *BAUCANT* and *JAZZ*.

GIRDEBS, in *Architectura*, the largest pieces of timber in a floor. Their ends are usually tapered into the corners, or breast-summers; and the joints are framed in at one end to the *girders*.

In the theatre for rebuilding London, no *girder* is to lie less than ten inches into the wall, and their ends to be always laid in loam, &c.

Grades and Summer in Length	1 foot, in		must be in

GIRDING-beam, in *Building*, the same as *GIROUET*.

GIRDING-iron, in *Sea Voyages*. The seamen say a ship is *girded*, or hath a *girding-iron*, when her cable is to tight or straitened, that upon the raising of the tide cannot go over it with her stern up, but will lie across the tide.

GIRDL, *Cerviculus*, or *Zona*, a belt or band of leather, or other matter, tied about the reins, to keep that part more firm and tight.

It was anciently the custom for bankrupts, and other insolvent debtors, to put off and surrender their *girdle* in open court. The reason hereof was, that our ancestors used to carry all their necessary utensils, as purses, keys, &c. tied to the *girdle*; whence the *girdle* became a symbol of the estate. Hilbery relates, that the widow of Philip I. duke of Burgundy, renounced her right of succession by putting on her *girdle* upon the duke's tomb. The Romans always wore a *girdle*, to tuck up the tunica

when they had occasion to do any thing; this custom was so general, that such as went without *girdles*, and let their gowns hang loose, were reputed idle, dissolute persons.

GIRDL, *Malden*, or *Fergan*. It was the custom among the Greeks and Romans, for the husband to untie his wife's *girdle*. Homer, lib. xi. of his *Odyssey*, calls the *girdle* *capitulum* *curvi*, *multi girdle*. Pothus relates, that it was made of Isaac's wool, and that the husband untied it in bed; he adds, that it was tied in the Herculean knot; and that the husband untied it, as a happy presage of his having as many children as Hercules, who at his death, left seventy behind him.

The poets attribute to Venus a particular kind of *girdle*, called *castoreo*, to which they annexed a faculty of inspiring the passion of love.

GIRDL, *poisonous*, in *Medicine*, is a sort of *girdle*, incased over with mercury, or having mercury inclosed within it.

It is made of leather, linen cloth, cotton, fluff, or the like; and the mercury is prepared or killed various ways; as with salting, spittle, fat, or the like.

It is applied as a topical medicine about the waist, sometimes with good effect; but, frequently, it proves dangerous, principally in weak constitutions, and those subject to convulsions. Its intention is, the cure of the itch, driving away vermin, killing lice, &c.

GIRDL, *Sevens*, is an ancient day or tax, raised in Paris every three years, at the rate of three deniers upon each muid of wine, and six for each quene; it was intended for the maintenance of the queen's household; afterwards they augmented and extended it to other commodities, as coach, &c.

Vigenero supposes it to have been originally thus called, because the *girdle* anciently served for a purse; but he adds, that a like tax had been raised in Persia, and under the same name, above two thousand years ago; as appears from Plato, in his *Alcibiades*, Cicero, *Atticus*, &c.

GIRDL, *Christian* of the, Motesackel, tenth Caliph of the family of the Abbassides, expelled the Christians and Jews, in the year of the Hegira 235, of Jesus Christ 856, to wear a large leathern *girdle*, as a badge of their profession; which they bear to this day throughout the East: from thence time the Christians of Asia, and particularly those of Syria and Mesopotamia, who are almost all Nestorians or Jacobites, have been called *Christians of the Girdle*.

GIRDL, *order of the*, the order of Cordons. See *CORD* and *CORDELLIER*.

GIRDL, in *Architectura*. See *CIRCULAR*.

GIRDL, among *Traders*, the line which encompasses the globe, parallel to the horizon; or, which determines the greatest horizontal expansion of the globe.

GIRDL, *wheel*, a small spinning-wheel, made for hanging to a woman's girdle or apron-string, so that the may spin with it though walking about.

GIRGLIM, in the *Matéria Medica*, a name given by some authors to the fetanum, or oily purging grain.

GIRGITES, a name used by some chemical writers for a sort of white stones found in green, of which they make a peculiarly strong lime. The stones are of the sparry kind, worn into roundels by the motion of the water; and they have their name *girsites*, from the word *gir*, used by the chemists for lime.

GIRKIN, among *Gardeners*. See *GUTTERIN*.

GIRLE, among *Spirituaries*, denotes the too-buck in its second year.

GIRNER, a word used by some of the chemical writers to signify tartar.

GIRON, or *GIROU*, in *Herakley*, denotes a triangular figure, having a long sharp point, not unlike a wedge, terminating in the centre of the sphenon.

The word is French, and literally signifies the *geranium*, or *jay*, because, in fitting, the knees being supposed somewhat adumbrated, the two thighs, together with a line imagined to pass from one knee to the other, form a figure somewhat similar to this.

When a coat has six, eight, or ten of these *girs*, meeting or crossing in the middle of the coat, it is said to be *girsed* or *girsed*.

GIRROCK, the common English name of the fish called the *LICHTYUS*, a large species of gar-fish, caught in the Mediterranean and English seas.

GIRONNE, *Girony*, in *Herakley*, is when a shield or coat is divided into several girs, which are alternately colour and metal. See *Tab. II. Herald. Fr. 63*, which is blazoned *gironi* of six argent and sable.

When there are eight pieces, or girs, it is absolutely said to be *girsed*; when there are more, or fewer, the number is to be expressed: *girsed* at four, of fourteen, &c.

Some,

Some, instead of *gironi*, say, *parti*, *cruppi*, *tranchi*, and *taili*, because the gironi are formed by such divisions of the field. Four gironi form a *SALTIER*, and eight a cross.

GLASS, in measuring TIMBER, is used for the circumference of a tree. See *Campbell's SLIDING-rule* and *DENDROMETER*.

Some call the fourth part of the circumference of the *girt*, and suppose the square of this equal to the area of the section of the tree.

GLASS, in *Architecture*, the same with fillet. See *FILLET*.

GLASS, in *Sea Language*. See *GARDING-girt*.

GIRT-line is a rope pulling through a single block, on the head of the lower masts, to hoist up the rigging thereof: this is the first rope employed to rig a ship, and by means of this all the rest are drawn up and fixed; after which it is removed until the ship is to be unrigged.

GIRTHS of a *saddle*, the strong straps, made of a canvas strip called *girth-web*, which being buckled under the horse's belly, serves to fix the saddle.

GISARMS, or *GISSARMS*, in *an Old-Fishery*, an halibut or hand-axe: it comes from the Latin *gis arma*, because it wounds on both sides. Name. *Eft armum gis armum munda* in *peritida colide*. It is mentioned in the *Ritue* 1. c. 1. cap. 1.

GISCARA, a name used by some botanical authors for the *palma confusa* near *Boopha*, a small palm common in the *Brasils*.

GISON, or *GETSON*, in the *Tenish Antiquities*, a little wall about breast high, made round the temple properly to call, and the altar of burnt sacrifices, to keep the people at a distance. Josephus, in his Book of Antiquities, makes it to be three cubits high: and but one, in his History of the Jewish war. *Jos. Ant. lib. viii. cap. 2. p. 202* & De Bella Jud. lib. vi. p. 118. *Calm. Dict. Bibl.*

GITHAGO, in *Babyn*, a name used by some authors, particularly by *Pliny*, for the jolam or daniel-grate.

GITHILL. This word occurs frequently in the *Psalms*, and is generally translated *vine-pruin*. The conjectures of interpreters are various concerning this word *githil*. Some think it signifies a sort of musical instrument; others, that the *Psalm*, with this title, were sung after the vintage; lastly, others, that the hymns of this kind were invented in the city of *Gath*. Calmer is rather of opinion, that it was given to the class of young women, or long-haired of *Gath*, to be sung by them. *Pl. viii. 1. line 1. 2. verse 1.* Dr. Hammond thinks that the *Psalm*, with this title, were all set to the same tune, and made on *Guth* the *Githil*.

GIVEN, *Autum*, a term very frequently used in *Mathematics, signifying a thing which is supposed to be known.*

Thus, if a magnitude be known, or we can find another equal to it, we say, it is a given magnitude, or that such a thing is given in magnitude.

If the position of any thing be supposed as known, we say, given in position.

Thus if a circle be actually described on a plane, its centre is given in position, its circumference given in magnitude, and the circle is given both in position and magnitude.

A circle may be given in magnitude only; as when only its diameter is given, and the circle not actually described.

If the kind or species of any figure be given, they say, given in species. If a ratio between any two quantities is known, they are said to be given in proportion. See *THEO*.

GIZER, in the *Maoria Medica* of *Galen* and the ancients, a name given to the finest and best kind of casta fittus.

The ancients had several sorts of this drug, some collected separate from the wood, some with it, the young shoots being cut bark and all, and preferred together.

GLABELLA, *quid glabra*, a term used by some writers to express the space between the two eyebrows: it is so called from its smoothness, being usually without hair.

GLACIALIS, *ex, of, glacies, or*, something relating to ice; and particularly a place that abounds in ice.

Thus we say, the *Mors Glacialis*, or *Congelation*, that is, the Ice or Frozen Sea; called also the *Cherson* or *Sarmatian Sea*.

GLACIES Marine. See *SPERULACEAE lapin*.

GLACIS, in *Balning*, an easily identifiable slope or declivity.

The descent or inclination of the *glacis* is less steep than that of the *talus*. In gardening, a descent sometimes begins in *talus*, and ends in *glacis*.

The *glacis* of the cornish is an easy imperceptible slope in the cymium of the cornish, to promote the descent and draining off of the rain-water.

GLACIS, in *Fortification*, is particularly used for that of the counter-carp, being a sloping bank, which reaches from the parapet of the counter-carp, or covert-way, to the level side of the field, at the distance of about twenty fathoms. See *TAB. Fort. fig. 21. lit. a a a* and *a*.

The construction of the covert-way and *glacis* is more distinctly illustrated in *TAB. VITI Fort. fig. 41*. When the body of the place, and all the necessary out-works are constructed, lines are drawn parallel to the innermost counter-carp of the ditch, at six toises distant from it, and the space *m m n*, included between that line and the counter-carp, will be the *glacis*. A, in this figure, represents the *arrow*; B, the *detached abattment*; c, v, the *traverses*; d, z, the *salley-ways*. When the ground is low, and water to be found, there is often a ditch of about ten or twelve toises made round the *glacis* beyond which there is a formed covert-way of four toises, with traverses and places of arms, and a second *glacis* from fifteen to eighteen toises broad. Muller's *Fort. p. 42*.

GLADDON, or *GLADWIN*, the name of a plant otherwise called *Spargan-vort*.

GLADE, in *Agriculture*, *Gardening*, &c. a wide, or open and light passage made through a thick wood, grove, or the like, by topping off the branches of trees along the way.

GLADE, in *Zoology*. See *GERAD*.

GLADIATORS, in *Antiquity*, persons who were retained to fight ordinarily in the arena, for the entertainment of the people.

The *gladiators* were usually slaves, and fought out of necessity; though, sometimes, freemen made profession thereof, like our prize-fighters, for a livelihood. After a slave had served on the arena three years, he was dismissed.

The Romans borrowed this cruel diversion from the *Africans*: some suppose that there was policy in this practice, the frequent combats of *gladiators* tending to accustom the people to despise dangers and death.

The origin of such combats seems to be as follows: from the earliest times with which we have any acquaintance in profane history, it had been the custom to sacrifice captives, or prisoners of war, to the manes of the great men who had died in the engagement; thus *Adrius* in the *Iliad*, lib. xxiii. sacrifices twelve young *Trojans* to the manes of *Patroclus*; and in *Virgil*, lib. xi. ver. 86. *Aeneas* sends captives to *Eneas*, to be sacrificed to the funeral of his son *Pallas*.

In course of time they came also to sacrifice slaves at the funerals of all persons of condition; this was even esteemed a necessary part of the ceremony; but, as it would have appeared barbarous to have massacred them like beasts, they were appointed to fight with each other, and endeavour to save their own lives by killing their adversary. This seemed somewhat less inhuman, because there was a possibility of avoiding death, by an exertion of skill and courage.

This occasioned the profession of *gladiator* to become an art: hence arose masters of arms, and men learned to fight and exercise this art.

These masters, whom the Latins called *lanista*, bought them slaves to be trained up to this cruel trade, whom they afterwards sold to such as had occasion to present the people with so horrible a show.

They were at first performed near the sepulchre of the deceased, or about the funeral pile; but were afterwards removed to the circus and amphitheatres, and became ordinary amusements.

The first show of *gladiators*, called *munus gladiatorum*, was exhibited at Rome, according to *Valerius Maximus*, by *M. and D. Brutus*, upon the death of their father, in the year of the city 400. On this occasion there were probably only three pairs of *gladiators*: in the year of Rome 537, the three sons of *M. Aemilius Lepidus* the augur, who had been three times consul, entertained the people with the cruel pleasure of seeing twenty-two *gladiators* fight in the forum. In the year of Rome 547, the first *Africanus* diverted his army at New Carthage with a show of *gladiators*, which he exhibited in honour of his father and uncle, who had begun the reduction of Spain. In process of time, the Romans became so fond of these bloody entertainments, that not only the heir of any great and rich citizen lately deceased, but all the principal magistrates, presented the people with shows of this nature, to procure their affection. The *praetor*, *consul*, and, above all, the candidates for offices, made their court to the people, by entertaining them frequently with these fights: and the *praetor* was sometimes the exhibitor of the barbarous show: for we meet with the *ludi pistoriales* in *Suetonius*, *Aurull. cap. 44* and with the *ludi gladiatori*, in *Pliny*, *Epist. lib. vii.*

As for the emperors, it was so much their interest to ingratiate themselves with the populace, that they obliged them with combats of *gladiators* almost upon all occasions; and as these increased, the number of combatants increased.

created

created likewise. Accordingly, Julius Cæsar, in his address, directed the people with three hundred and twenty couple. Titus exhibited a show of *gladiators*, wild beasts, and representations of sea-fights, which lasted a hundred days; and Trajan continued a solemnity of this nature for a hundred and twenty-three days, during which time he brought out a thousand pair of *gladiators*. Before this time, under the republic, the number of *gladiators* was so great, that when the conspiracy of Catiline broke out, the senate ordered them to be dispersed into the garrison and secured, lest they should have joined the dissipated party. See *GLADIATOR*'s *mur*.

These sports were become so common, and their consequences, in a variety of respects, so dangerous, that Cicero preferred a law, that no person should exhibit a show of *gladiators* within two years before he appeared candidate for any office. Julius Cæsar ordered, that only a certain number of men of this profession should be in Rome at a time. Augustus decreed, that only two shows of *gladiators* should be presented in a year, and never above fifty couple of combatants in a show. And Tiberius provided, by an order of the senate, that no person should have the privilege of gratifying the people with such a solemnity, unless he was worth four hundred thousand sesterces. They were also considerably regulated by Nerva.

The emperor Claudius restrained them to certain occasions; but he soon afterwards annulled what he decreed, and private persons began to exhibit them at pleasure, as usual; and hence carried the brutal satisfaction so far as to have them at their ordinary feasts.

And not slaves only, but other persons, would hire themselves to this infamous office.

The master of the *gladiators* made them all *sist* (wear), that they would fight to death; and if they failed, they were put to death, either by fire; or by swords, clubs, whips, or the like.

It was a crime for the wretches to complain when they were wounded, or to ask for death, or seek to avoid it, when overcome; but it was usual for the emperor, or the people to grant them life, when they gave no signs of fear, but waited the fatal stroke with courage and intrepidity. Augustus even decreed, that it should always be granted them.

From slaves and freedmen, the inhuman sport at length spread to people of rank and condition; so that Augustus was obliged to issue a public edict, that none of the senatorian order should become *gladiator*; and soon after he laid the same restraint on the knights; nevertheless, Nero is related to have brought upwards of four hundred senators, and six hundred Roman knights upon the arena; though Lippus takes both these numbers to be falsified, and not without reason, reduces them to forty senators, and fifty knights; yet Domitian, that other monster of cruelty, reined upon Nero, exhibiting combats of women in the night-time.

Constantine the Great is said to have first prohibited the combats of *gladiators* in the East; at least, he forbade those who were condemned to death for their crimes, to be employed; there being an order still extant to the prefects prætorii, rather to send them to work in the mines in lieu thereof; it is dated at Berytus, in Phœnicia, the first of October, 325.

The emperor Honorius forbade them at Rome, on occasion of the death of Telemachus, who coming out of the East into Rome, at the time of one of these spectacles, went down into the arena, and used all his endeavours to prevent the *gladiators* from continuing the sport; upon which the spectators of that carnage, fired with anger, flung him to death.

It must be observed, however, that the practice was not entirely abolished in the West before Theodoric, king of the Ostrogoths. Honorius, on the occasion first mentioned, had prohibited them; but the prohibition does not seem to have been executed. Theodoric, in the year 500, abolished them finally.

Some time before the day of battle, the person who presented the people with the shows, gave them notice thereof, by programmes, or bills, containing the names of the *gladiators*, and the marks whereby they were to be distinguished; for each had his several badge, which was, most commonly, a peacock's feather, as appears from the scholiast of Juvenal, on the 138th verse of the third Satire, and Turneb. *Advers.* lib. ii. cap. 8.

They also gave notice what time the shows would last, and how many couples of *gladiators* there were; and it even appears, from the 3rd verse of the seventh Satire of the second book of Horace, that they sometimes made representations of these things in painting, as is practiced among us by those who have any thing to show at fairs.

The day being come, they began the entertainment by bringing two kinds of weapons; the first were staves, or wooden files, called *rudis*; and the second were defensive weapons, as *scutis*, *pinnæ*, &c.

The first were called *arma levis*, or *causidarii*; the second *causidarii*, as being given by decree or sentence of the prætor, or of him at whose expense the spectacle was exhibited. They began to fence or skirmish with the first, which was to be the prelude to the battle; and from these, when well warmed, they advanced to the second, at the sound of the trumpet, with which they fought naked.

Then they were *ardentes arma*, the terms of striking were *perire* or *capere*; of avoiding a blow, *evadere*; and when one of the combatants received a remarkable wound, his adversary or the people cried out *Lacet*, or *capitacet*. The first part of the engagement was called *mutualis*, *periculis*; and the second, *summe ad certum*, or *certis armis pugna*; and some authors think, with much probability, that it is to these two kinds of combat that St. Paul alludes, in the passage 1 Cor. ix. 26, 27. "I fight, not as one that beateh them; but I keep my body, and bring it into subjection."

If the vanquished surrendered his arms, it was not in the victor's power to grant him life; it was the people, during the time of the republic, and the prætor or people, during the time of the empire, that were alone empowered to grant the boon.

The reward of the conqueror was a bunch of palm-tree, and a sum of money, probably collected among the spectators; sometimes they gave him his conge, or dismissed him, by putting one of the wooden files or *rudis* in his hand; and sometimes they even gave him his freedom, putting the pileus on his head.

The sign, or indication, whereby the spectators shewed that they granted the favour, was *proferre piliu*, which M. Dacier takes to be a clenching of the fingers of both hands between one another, and to holding the two thumbs upright close together; and, when they would have the combat finished and the vanquished slain, they *retorserunt piliu*, bent back the thumbs; which we learn from Juvenal, Sat. iii. ver. 36.

The *gladiators* challenged or defied each other, by flexing the little finger; and, by extending this, or some other, during the combat, they owned themselves vanquished, and begged mercy from the people: *Vixi, jam dixi tantum a populo periculis*, says the scholiast on Persius. Vide Plin. lib. xxviii. cap. 2. Prædilectus, lib. ii. contra Symon. ver. 1095. Horace, lib. iv. 18. ver. 66. Polian. Miscel. cap. 49. Turneb. *Advers.* lib. ii. cap. 6. Lipp. Saturn. lib. ii. cap. 21.

There were divers kinds of *gladiators*, distinguished by their weapons, manner, and time of fighting, &c.; as the *andabata*, of whom we have already given an account under *ANDABATA*.

The *veterarii*, who always fought in troops or companies, number against number; or according to others, who fought promiscuously, without any certain order. Lipp. lib. ii. cap. 16.

The *causidarii*, whom authors mention as a species of *gladiators*, the same with the *rudarii* and *veterarii*; founding the opinion on a passage in Pliny, lib. viii. cap. 7. But Lippus shews, that they have mistaken Pliny. Saturn. lib. ii. cap. 16. and Turneb. *Advers.* lib. xi. cap. 36.

The *causidarii*, which are a little precarious, being chiefly founded on a passage in Lampadius, in the life of the emperor Commodus: *Inter hæc, habuit costumarii, vestitus simulavit, ut arena rudarii, inter causidarii, gladiatores pagani et incertis alioquin non videtur*. Turneb. reads *rudarii* instead of *causidarii*; and understands it of those who had been dismissed, and could no longer be obliged to fight, except with files.

Salustius reads *gladiatores*, and refers it to the emperor, who fought not only on the arena, and with files, or blunted instruments, but at home, with his servants and with his children, and with sharp.

Lippus will have nothing altered in the text: the *gladiatores causidarii*, he observes, were those who fought at private boxes, during feasts, &c. Accordingly, Dion says expressly, that Commodus sometimes fought at home, and even killed some persons in such encounters; but that, in public, he only fought with blunted weapons.

The *dimachi*, who fought armed with two pinnæ, or swords; or with sword and dagger. Lipp. Saturn. lib. ii. cap. 12.

The *effidarii*, who fought in pairs; called also, in an inscription lately discovered at Lyons, *effidarii*. Saturn. *serm.* lib. ii. cap. 12.

The *flutis*, or *Cæsariani*, who belonged to the emperor's company; and who, being more robust and dexterous than the rest, were frequently called for; and therefore

therefore named also *pylathini*. Saturn. lib. ii. cap. 16. The other kinds were, the *hepmachi*, *metidiani*, *myridiani*, *adarni*, *pluniani*, *procatarii*, *relarii*, *rufarii*, *Samitii*, *fecutarii*, *steltarii*, and *Thracii*: which see described under *MIRIDIANI*, *BAITARI*, *SECUTORES*, &c.

Some authors, and particularly Vigener on Livy, rank the *obseques*, mentioned by Spartian, in his life of Marcus Aurelius, among the number of *gladiators*: Lipfius laughs at him, Saturn. lib. ii. cap. 10. and with some reason: the *obseques* properly were the troops which that emperor raised among the *gladiators*; or whom of *gladiators* he made soldiers.

GLADIATORS *war, bellum GLADIATORUM*, or *Spartianum*, called also the *ferule war*, was a war which the Romans sustained about the year of their city 680. Spartacus, Crinua, Oronotus, having escaped, with other *gladiators*, to the number of twenty-four, out of the place where they had been kept at Copia, gathered together a body of slaves, not themselves at their head, rendered themselves masters of all Campania, and gained several victories over the Roman praetors. At length they were defeated, in the year 682, at the extremity of Italy; having, in vain, attempted to pass over into Sicily.

This war proved very formidable to the Romans. Crassus was not able to finish it: the great Pompey was forced to be sent as general.

GLADIATOR, *syn.*, is a most valuable monument of ancient sculpture, which is now preserved in the palace of Chigi. This man, when he had received the mortal stroke, is particularly careful, at *periculis* *hughe*, that he might fall honourably; he is seated in a reclining posture on the ground, and has just strength sufficient to support himself on his right arm; and in his expiring moments it is plainly seen that he does not abandon himself to grief and dejection, but is solicitous to maintain that firmness of aspect, which the *gladiators* valued themselves on preserving in this season of distress, and that attitude which they had learnt of the masters of defence. He fears not death, nor seems to betray any token of fear by his countenance, nor to shed one tear: *quis audaci gladiator ingenui, quis vultum natusit angustum, quis non nudis fletu, variis etiam decubuit torpore, laevi Cicero*, in that part of his Tullian, where he is describing the astonishing firmness of these persons. We see, in this instance, notwithstanding his remaining strength, that he has but a moment to live, and we view him with attention, that we may see him expire and fall: thus the ancients knew how to animate marble, and to give it almost every expression of life. Encyclopedie.

GLADIOLUS, in *Italy*. See *CURVLAG*.

GLADIUS, *juris*. *Jus GLADIUM*, or right of the sword, is used, in our ancient Latin authors, and in the Norman laws, for supreme jurisdiction.

Camden, in *Britannia*, writes *Comitatus Flint pertinet ad gladium Castris*: and Selden, Tit. of Honour, p. 640. *Coram sum librum de omnibus plantis, &c. exceptis ad gladium qui pertineturibus*.

And it is probably from hence, that, at the creation of an earl, he is *gladius facit*; to signify, that he had a jurisdiction over the county.

GLADIUS *passiv*, in *Ichthyology*, a name used by many for the sword-fish, called also the xiphias.

GLADWIN. See *TALE*.

GLAIR of *egg*, is the same as the white of egg, and is used as a varnish for preserving paintings. For this purpose it is beat to an unctuous consistence, and commonly mixed with a little brandy or spirit of wine, to make it work more freely, and with a lump of sugar to give it body and prevent its cracking: and then spread over the picture or painting with a brush.

GLAMA, in *Natural History*, the name of a species of CAMEL, called also *rhaphanum*; by many authors, and by many erroneously accounted a sheep: its length from head to tail is about six feet; its height about four feet; its head, neck, and the general appearance of the upper part of the body, greatly resemble the camel; and its upper lip is divided in the same manner as in that creature. Its parts of generation we also the same as in the camel, and it is destitute of the fore-teeth, and chews the cud like other animals that are so. It has no horns, and its feet are divided into two portions, which terminate in a sort of claws, and are faltered by a skin round the anterior part of the foot; the sole of the feet is tender, and covered over only with a thick skin, as in the camel.

It has at the place where the breast joins to the belly a protuberance, like that which the camel and *aromelary* have in the same part, and in this animal Matthiolus observes that there is a continual discharge of a sort of liquid excrement from it: but this has been supposed by

VOL. II. N° 122.

some to be only accidental. It is a very tame animal, and fit for domestic uses. It never offends any creature; but when provoked, revenges itself by discharging the contents of its stomach, by vomit, upon whatever injures it, and this it will do to a great distance.

The flesh of this animal is eaten, and said to be as good as mutton.

It is a native of Peru, and is of vast use to the inhabitants for carrying burdens; the weaker of them very easily carry a hundred and fifty pounds weight, and the stronger two hundred and fifty. Ray's *Syn. Quak.* p. 143.

The *glauco* of Peru may probably be the *glama* in its wild and savage state: there are very timid and wary animals; for, whilst they are feeding in great herds on the hills, one keeps watch, and on perceiving the approach of any one, night, and thus gives the alarm to the herd, which run off with incredible speed. They are killed for the sake of their flesh, and of their hair, which the Indians weave into cloth. Pennant's *Synop. of Quak.* p. 66.

GLAMA, in the *Old Writers of Medicine*, is sometimes used to signify the fibres of the eyes in *leptitudes*, and other disorders attending them.

GLAND, **GLANDULA**, in *Anatomy*, a soft, spongy, lax kind of body; serving to separate some particular humour from the mass of blood.

The ancients took the *glands* to be nothing more than a kind of pillow, or cushions, for the neighbouring parts to rest on. Some of them, at length, began to fancy them sponges, destined to receive and imbibe the superfluous moisture of the other parts.

Later physicians thought proper to assign them nobler and more important uses. They considered them as cisterns, which contain proper ferments, whereby the blood, upon its mixing therewith, was put into a fermentation; in the progress whereof it worked, or threw off certain of its parts, and sent them away by excretory ducts.

The moderns, who allowed the *glands* to be the organs whereby the vital fluids are separated for the uses of the body, considered them as filters, the pores whereof, being of different sizes, would only admit of similarly figured particles to pass through them.

But the latest authors rather conceive the *glands* as sieves, whose perforations, being of different sizes, though of the same figure, only separate such particles whose diameters are less than their own.

The *glands*, to the eye, appear a sort of whitish, membranous mass composed of an outer cover, or integument; within which a vascular plexus is contained. They are denominated from their resemblance, in form, to acorns, which the Latins call *glanulae*.

By dissection, and the microscope, they are found to be real plexuses or pectolones, of vessels, variously wound, and implicated among themselves: but the modern anatomists Malpighi, Bellini, Warion, Nuck, Peyr, &c. have gone farther; and discovered them to be no more than continued convolutions of the capillary arteries.

Their formation appears to be thus. An artery, arriving at a certain part, is divided into an infinite number of exceedingly fine branches, or ramifications: these capillary branches are laid in various beds, and circulations; and from the returns thereof arise new branches, or vessels for veins; which a little farther unite, or terminate, in some larger branch.

All these ramifications, both veins and arteries, are rolled up in a bundle; making numerous gyres, and circulations; and from the various bends and angles, formed by both kinds, arise numerous other minute vessels, which make the principal and most essential part of the *gland*.

The blood brought from the heart by the artery, into the glandular plexus, purifies all the turns and meanders in the arterial part thereof, till, arriving at the venous part, it is by it brought back again to the heart: in the mean time, during its progress through the arterial and venous folds, some part of it is absorbed, or drained off, at the orifice of the tubules arising from the flexures thereof.

What is thus received into these, which we may call the *secretory ducts*, is commonly taken up by other tubules, springing out of them: these, joining together, form a single canal, which is called the *excretory duct*; which, passing out of the body of the *gland*, carries off the secreted matter into some proper receptacle destined to retain or receive it.

Though, sometimes, the secretory vessels themselves terminate in a basin or reservoir; and deposit their contents therein. Such is the general structure, and office of the *glands*; which we shall farther illustrate, under *SECRETION*.

A *gland*, then, is a composition of divers kinds of vessels;

islets; viz. an artery, and a vein; secretory and excretory ducts: to which may be added, a nerve, which is found in every gland, diffused through the whole substance thereof, to furnish spirits for promoting the secretion; and a membrane, which supports the convolutions of the vein and artery, accompanying them together through all the minutest divisions: to which add, lymphatics, which have been discovered in several glands.

The secretory tubes, however, are what we principally consider as the organ of the gland: these, alone, sometimes form the greatest part of what is called a gland, or glandular body.

The glands are liable to be so altered by accidents as to be scarce known for what they really are; and their different temperatures are too often productive of the most mischievous consequences. The Paris memoirs give an account of a woman, who, attempting to lift a large weight, had a swelling that appeared the same day on the lower part of her arm, which continued increasing in size for eighteen months. After this there appeared a hole in the inner part of the hand, from which there was discharged a quantity of matter daily, but yet the swelling continued to increase. At the end of two years she consented to have it laid open. There was very little matter discharged, the whole not amounting to more than two spoonfuls of a thick viscous fluid; all the rest of the tumor was solid, and contained about two hundred white bodies, of a roundish, but somewhat oblong figure, and not much resembling some of the kinds of kidney-beans. These were covered with a solid membrane, and had no cavity within: and some of them had at one end a sort of stalk, or pedicle, by which they seemed to have been fastened to some other body. These were the glands which had lost their natural use, and were become hard, and what seemed a pedicle or stalk to some of them was their excretory duct which had not perished. Mem. Acad. Par. 1708.

The glands which have no particular secretory ducts, are called *glandulae cereae*, or *clausae*.

Dr. Quercetius argues for these glands being designed to prepare nourishment for the other parts, from the observation that they decrease after birth to full growth, then continue in the same condition till old age comes on; after which they gradually thrive. Select. Medic. Francosurt. tom. ii. vol. i. § 3.

M. Winslow has discovered a kind of tomentum, or down, within their cavity, which he supposes to do the office of a filter, and to be that whereby such a certain humour is separated from the common mass of blood. His system will be explained, when we come to treat of secretion.

The downy vessel being the grand organ of secretion, its structure and application are diversified, according to the different purposes nature has in view. Sometimes the liquor, filtrated through it, trickles out, drop by drop, upon a membrane, to which one extremity of the vessel is fastened; as where the filtration is only intended for moistening and lubricating the part with that liquor: in which case, the downy vessel is both secretory, and excretory; which is the most simple case. Such are those innumerable glands spread through the greater part of the viscera.

Sometimes a great number of these downy vessels are spread over the inner surface of a little membranous cell, into which they all pour their liquor, which is discharged hence at a little aperture in the cell. Such are the follicular glands of the intestines, which appear like so many little separate grains.

Sometimes a vessel is bent, and has only down in the first part thereof, which alone is secretory, and the rest excretory, pouring the liquor into some other common cavity. Such are the glands that compose a calf's kidney.

The secretory vessels are sometimes of a very great length, notwithstanding that they take up but little room; being wound over themselves, again and again, sometimes in a single pedion, or knot; and sometimes in several, inclosed in a common membrane.

The glands are of several kinds, in respect to their form, structure, office, and use: authors usually divide them into *conspicuae* and *inconspicuae*.

GLANDS, *conspicuae*, or *conspicuae*, are those consisting of one continuous mass, with an uniform surface. Such are tuberculous glands.

A conglobate gland is, more strictly, a little smooth body, wrapped up in a fine double skin, by which it is separated from all the other parts; only admitting an artery and nerve to pass in, and a vein and excretory duct to go out.

These glands either discharge their secreted humour into the chyle, or veins; or blood; or else it transpires through the pores of their skin, or the coats of the looser membranes found in most parts of the body.

Of the conglobate kind are the glands in the cortical part of the brain, in which the animal spirits are supposed to be secreted: such, also, are the salivary glands and the testes. See **LYMPHATICS**.

GLANDS, *conglomerate*, or *conspicuae*, is an irregular assemblage of several simple glands tied together, and wrapped up under one common membrane. Such are the maxillary glands, &c.

The humours secreted in these glands are sometimes discharged at a common excretory duct, formed of an union of the excretory ducts of all the particular ones: this is the case in the pancreas, and parotides.

Sometimes the ducts, uniting, form several tubes, only communicating with each other by cross canals; as in those of the breasts.

Some again, have several excretory tubes, without any communication together: as the glandulae lacrymales, and prostates.

Others have their several excretory ducts inserted into a common canal, which opens, at last, into some of the greater cavities: as the salivary glands, intestinal glands, &c.

Lastly, in others, each gland has its own excretory duct, through which it transmits its liquor into a common basin: such are those of the kidneys.

Some suppose and endeavour to prove the necessity of vessels to the conglomerate glands, in order to receive all the different particles required in the composition of secreted liquors, which must be conveyed in different series of vessels, to be intimately blended in the vesicle, which will be considerably assisted by the syphole and dia-phole, which it is supposed the vesicle undergoes. See Acad. Bonon. Com. p. 336.

The glands are again divided into *vascular*, and *avascular*.

GLANDS, *vascular*, are only clusters of little vessels, which, uniting together, form the canal, or excretory duct, through which the secreted juice is discharged.

GLANDS, *vascular*, are assemblages of vesiculae communicating with each other, and all terminating in two or three large vessels; by a prolongation whereof, the excretory duct is formed.

The glands, again, are divided into the *adventitious*, and the *perpetual*, or *natural*.

GLANDS, *adventitious*, are those kernels arising occasionally under the arm-pits, on the neck, &c. Such are the strumae, and the tumors found on the larynx, and middle of the trachea.

GLANDS, *perpetual*, or *natural*, are of two kinds; conglobate, and conglomerate, as above described.

GLANDS of the *arteria aspera*. See **ARTERIA ASPERA**.

GLANDS, *axillares*, are those situated in the axilla, or arm-pit. See **HICETUS**.

GLANDS of the *Breast*. See **BREAST**.

GLANDS, *bronchiales*. See **BRONCHIALES**.

GLANDS, *buccales*. See **BUCCALES**.

GLANDS, *ceruminosae*, are those which serve to separate the ear-wax, or cerumen. See **EAR**.

GLANDS, *ciliari*. See **CILIA**.

GLANDS, *cystic* and *hepaticae*. See **LIVER** and **BILE**.

GLAND, *desul*, is found in the thorax, about the fifth vertebra of the back, adhering to the posterior part of the oesophagus. In different subjects it is of various sizes: but it is commonly about the size of an almond; though it is sometimes so small as not to be found without great difficulty. Two glands are sometimes seen in this part. The *desul* gland has been described by Vesalius and other ancient anatomists. Some have supposed that this gland serves to secrete a fluid to assist digestion, and others that it discharges a mucous fluid into the cavity of the oesophagus.

GLANDS, *inguinal*, are situated on each side in the groin, near the crural vessels, and, in various diseases, are apt to become tumid and inflamed. Abscesses are often formed in these glands.

GLANDS, *intestinales*. See **INTESTINES**.

GLANDS, *jugulares*. See **JUGULAR**.

GLANDS, *labiales*. See **LIPS**.

GLANDS, *lacrimal*. See **LACHRYMAL**.

GLANDS, *lumbal*, *glandula lumbare*, are three glands thus called by Bartholin, as lying on the loins.

The two largest lie upon one another, betwixt the descending aorta and aorta. In the angle made by the emulgent with the vena cava, the third, and smallest, stands; the former, under the appendices of the diaphragm, they communicate, and are connected together by small lateral vessels. Bartholin concluded them to serve as a common receptacle of the chyle; but Dr. Wharton's opinion is more probable, viz. that they supply the place of those larger glands found in the infancy of lutes.

GLANDS, *lymphaticae*. See **LYMPHATICS**.

GLANDS, *maxillares*. See **MAXILLARY**.

GLANDS, *menses*. See **MENTERY**.

GLANDS, *miliary*, *glandulae miliari*. See **MILIARY GLANDS**.

GLANDS,

GLANDS, malar. See MALAR.

GLANDS, mucilaginous. See MUCILAGINOUS glands.

GLANDS, mucous, glandulae mucosae. See MUCOUS glands.

GLANDS, myrtiform, are contractions of the hymen, broke by the full act of venery. See CARUNCULA myrtiformis and HYMEN.

GLANDS, Nuckian. See NUCKIAN.

GLANDS, scirrhous, glandulae scirrhosae, are certain small glands, discovered by Dr. Tyson, in that part of the PENIS where the prepuce is contiguous to the balanus.

He gave them the name from the brisk scent which their separated liquor emits. In such persons as have the prepuce longer than ordinary, these are not only more in number, but larger, and separate a greater quantity of juice, which, lodging there, often grows rancid, and corrupts the glands. These glands are very conspicuous in most quadrupeds, especially in dogs and the boar.

GLANDS of the oesophagus. See OESOPHAGUS.

GLANDS, palatine. See PALATINE.

GLANDS, parotid. See PAROTID.

GLAND, pineal, glandula pinealis. See PINEAL gland and COSSARION.

GLAND, pituitary, glandula pituitaria. See PITUITARY gland.

GLANDS, renal, glandulae renales, called also *capsulae atrabiliaris*, are two glands, first discovered by Eustachius, between the aorta and the kidneys, a little above the emulgent vessels, though their situation and figure are varied; in some they are round, in others square, triangular, &c. The right is usually bigger than the left, and each about the size of a mus tomica: they are inclosed in fat.

Their use is not certainly known: it is supposed to be to separate a liquor from the arterial blood, before it goes to the kidneys. See CAPSULA atrabiliaris.

Mr. Du Vernoy remarks the *glandula renalis* to be very variable in their magnitude, figure, &c. but that they are always contiguous, and firmly connected to the kidneys. In some females they appear solid, without any cavity; in others, they are distended with thin blood; in adults, they are always flat: they are readily distended, by blowing air into them by the vein. When the glands are opened, and quicksilver is injected, a great many ducts are seen, at which the mercury runs out. Two arteries and a vein belong to each gland, and a great many ducts, like rays, make a circle round it. An artery, arising from the aorta, is sent down from the lower edge of the gland to the testes of men, and ovaria of women, which Valisera miltook for ducts. Comment. Acad. Petrop. tome v. See RENES laeunariata.

GLANDS, salivary. See SALIVARY.

GLANDS, sericous, glandulae sericae, are a number of glands placed under the skin of the auricle of the ear, first discovered by Valisera, and thus denominated, because they secrete a greasy matter, like sebum, or tallow.

This sebum, he asserts, being carried to the surface of the skin, turns it into a scaly substance, not unlike bran. There are many glands, of different kinds, which bear this name from their use.

GLANDS, splenic. See SPLEEN.

GLANDS, sublingual. See SUBLINGUAL.

GLANDS, thyroid. See THYROID.

GLANDS, ulcers of. See CANCER and SCIRRHUS.

GLANDES urinae, a name used by some authors for the tuberos root of a plant of the LATHYRUS kind, called the *lathyrus repens tuberosus*.

GLANDERS, a filthy disease in a horse, consisting in a corrupt slimy matter, running from the nose, of a different colour according to the degree of the malignity, or as the infection has been of a shorter or longer continuance; being white, yellow, green, or black, sometimes tinged with blood.

Authors ascribe it to various causes: some to infection; some to a disorder of the lungs; others to the spleen; some to the liver; and others to the brain. Allet it has been of so long standing, that the matter is of a blackish colour, which is usually in its last stage, they suppose it to come from the spine; and hence they call it the *entraining of the spine*.

Kernels and knots are usually felt under the caul in this disorder; and as these grow bigger and more inflamed, the glanders increase more.

M. La Fosse, baron to the king of France, has lately taken great pains, by repeated dissections, to discover the source and cause of this disorder, and to ascertain the proper and effectual method of cure. He has distinguished seven different kinds of glanders, four of which are incurable. The first proceeds from ulcerated lungs, the purulent matter of which comes up the trachea, and is discharged through the nostrils, like a whitish liquor, appearing sometimes in lumps and grumes: the second is a watery humour, that usually seizes horses at the

decline of a disease caused by too hard labour, and proceeds from the lungs; the third is a malignant discharge, which sometimes attends the strangles, fills upon the lungs, and is discharged at the nostrils; the fourth is when an acrimonious humour in the ears, fills these parts; the fifth arises from a horse's taking cold: the sixth is a discharge from the frangles, which sometimes vents itself at the nostrils; the seventh, or real glanders, is that above described.

M. La Fosse, after examining, by dissection, the carcasses of glandered horses, and making a strict scrutiny into the state of the viscera, assisted in his enquiry by ingenious anatomists for the space of ten years, affirms this disease to be altogether local, and that the true seat of it is in the pituitary membrane which lines the partition along the inside of the nose, the maxillary sinuses or cavities of the cheek-bones on each side of the nose, and the frontal sinuses or cavities above the orbits of the eyes; that the viscera, as the liver, lungs, &c. of glandered horses are, in general, very sound; and, therefore, that the seat of the disorder is not in those parts, as many authors have asserted.

He found these cavities more or less filled with a viscous slimy matter; the membrane, which lines both them and the nostrils, inflamed, thickened, and corroded with forid ulcers, which, in some cases, had cut into the bone. He observes, that, when glandered horses discharge matter from both nostrils, both sides of the membrane and cavities were affected; but when they ran at one nostril only, that side only was found distempered; and if one gland only was affected, the horse discharged from one nostril only; but if both were affected, the discharge was from both. It has been observed, that the glanders in horses very much resembles a disorder in men, called the GREEN.

In this disease, if the matter sticks to the inside of the nostrils, like glue or stiff paste; if the inside of the nose is raw, and appears of a livid or leaden hue, and the matter becomes bloody, fetid, and of an ash colour; these symptoms are very unfavourable: but when only a limpid fluid is first discharged, and afterwards a whitish matter, the gland under the jaw does not much increase, and the disorder has been of no long continuance, a speedy cure may be expected. The cure of this milder kind of glanders may first be attempted by injections and fumigations. When these latter symptoms appear, the horse should first be bled, and treated as in the common disorder of cold; and then, let an emollient injection, prepared with a decoction of linseed, marsh-mallows, elder, chamomile flowers, and honey of roses, or such like, be thrown up as far as possible with a strong syringe, and repeated three times a day: if the running is not lessened or removed in a fortnight by these means, a restraining injection may be prepared with tincture of roses, lime-water, &c. and the nostrils fumigated with the powders of frankincense, mastic, amber, and cinnamon, burnt on an iron heated for that purpose, the fumes of which may easily be conveyed through a tube into the nostrils. When the disease is inveterate, recourse must be had to the operation of trepanning, which M. La Fosse performed on three horses, two of which discharged from one nostril only, and the third from both: he trepanned the two first on that side of the head which was affected, and the other on both sides, and found that the wound and perforation filled up with good flesh in twenty-six days, and the horses suffered no inconvenience from the operation. The method of performing this operation will be understood by means of fig. 22. *Tab. Miscell.* and the following explication: B, B, are two lines representing the bounds of the cerebellum, or back part of the brain, which commences from the line D. C C is a line, where the superior part of the sinus frontalis commences, together with a view of the bottom of the sinus, terminating between the lines D and E, where appears a substance in the form of a pear, which is the os ethmoidis, or sieve-like bone through which the olfactory nerves pass, communicating sensibility to the pituitary membrane. E represents the beginning of the maxillary sinus, terminating at M: the shaded space between these lines represents the great cavities. F is a bony partition, separating this sinus into two parts that have no communication; of which partitions there are sometimes two, represented by F and G. Some horses have neither of these. N shows the place of the cornets or horns; O, the redoubtings; P, their middle parts; Q, the lower part of them; and M, the bony pipe or canal which guards the maxillary nerve: A A is the septum narium, dividing the nose from top to bottom, and separating the two nostrils: L shows the place where the trepan should be applied, when there is reason to apprehend that the glanders is spread into the frontal sinus; E is the place where it should be applied

to cleanse the maxillary sinus, though the round spot between D and E is preferable, because one orifice in this place will serve to wash all the parts, both above and below, with one injection. It shows the place where another perforation should be made, as a drain for discharging the foul matter washed away by the injection; and this hole, kept open by a hollow leaden pipe, would, in all recent cases, be sufficient. I represent the injection thrown in by the syringe, which flows out by the orifice and the nostril K; and, during this part of the operation, the nostrils should be held close. If there should be two bones in the maxillary sinus, it is absolutely necessary to pierce through both, with a bistoury or sharp-pointed tube, as in the figure. The trepan should be directed towards the interior part of the nose, to prevent its being obstructed by the roots of the teeth. R is the trepan, S the handle which turns it, and T the saw-part to be applied to the bone. The surgeon's trephine will answer the purpose for this operation; but before the instrument is applied, a circular piece of the skin, of about the size of half a crown, should be first cut off with the membrane which covers the bone. The syringe should be large enough to contain half a pint of injection. The injection first used should be of a desiccative nature, as a decoction of hith-wort, gentian, and centaury, to a quart of which may be added two ounces of Egyptianum and tincture of myrrh; and when the discharge abates, and the matter becomes of a thick consistence and white colour, this injection may be changed for barley-water, honey of roses, and tincture of myrrh; and for completing the cure, Bates's alum-water, or a solution of colcothar, vitriol, lapis medicamentalis, and such like, in lime water, will serve to dry up the moisture, and to restore the tone of the relaxed glands. For this purpose Dr. Bracken recommends the following mixture: take of alum and white vitriol, powdered, of each four ounces; calcine them in a crucible, when cold, powder the calx, and mix it with a gallon of lime-water and a quart of vinegar, and decant the mixture clear for use. The perforations that are made in this operation should be kept open, after the use of the injection, by fitting to the upper one a piece of cork waxed over, and a hollow leaden tent to the lower, through which there will be a constant drain of matter from the sinusses; and both may be secured by a proper bandage. The growth of the flesh should be also checked by rubbing with caustic medicine, or applying the actual cautery. The cure will be expedited, by giving every day a quart or three pints of a strong decoction of guaiacum chips, by purging at proper intervals, and putting a rowel into the horse's chest; and if these fail, mercurials may be administered with the physic, and the alterative powders with lime-water may be given and continued for some time.

The following remedy is said to have succeeded, in fifty cases out of sixty, for curing the *glanders*, without trepanning. Keep the horse a day or two with small quantities of choice hay, and scalded bran; then blow up his nostrils as much as affluence, in fine powder, as will lie on a six-pence, evening and morning, giving him for drink small lime-water, during four or five days; then boil two ounces of elecampane roots in a quart of milk, till they mix, and give it once a day during three or four days more; then boil two handfuls of the white mofs that grows on oaken poles, in two quarts of milk, till one is consumed; strain it and squeeze the mofs and give the milk just warm: repeat this for four or five days. About an hour after the horse has had his drink each day, take a piece of sweet butter, about the size of an egg, and about half an ounce of bitumene finely powdered, and work them well together; then take two clean goose feathers, as long as they can be procured, and make a hole in each of the quill end, in which insert two long threads; then moisten the feathers well with the mixture, and roll them in dry flower of brimstone; open the horse's nostrils, and thrust the feathers up into his head, filling the threads to the top of his head, to prevent their dropping out: take him in four or two morning and evening, and let him stand half an hour after he returns to the stable before the feathers are taken out: pursue this course eight or nine days, bathing his head with camphorated spirit of wine, and afterwards confusing his head over a tub of hot grains, that he may breathe the steam. A rowel may prevent a relapse.

GLANDULA, in *Anatomy*, the same as **GLAND**.

The word is a diminutive of the Latin *glan*, *quern*; and is here used on account of some external resemblance between the glands of the body and the fruit of the oak.

GLANDULA Glandini, among *Surgeons*, is a tumor resembling a gland; soft, single, moveable, with roots, and separate from the adjacent parts.

GLANDULE, in *English*, signifies a little gland. Thus the amygdalæ, or almonds of the ears, are by some called *glandulæ*.

GLANDULOUS, or **GLANDULAR**, something composed of glands, or that abounds with glands.

The **GREY MATTER** of the brain is commonly reputed to be *glandular*; though Raych, from the discoveries made by his admirable injections, holds, that there is no such thing as a gland there.

The ancients distinguished a particular kind of flesh, which they called *carne glandulosa*, or *glandulosa flesh*.

GLANDULOUS body, *glandulosa corpus*, much particularly denotes the PROSTATE.

GLANDULOUS roots, among *Botanists*, moist tubercle roots as are fastened together in large numbers by small fibres or threads.

GLANIS, in *Idiopathy*, the name of a fish, called in English the *shear-fish*, and in Latin *silurus*.

GLANS, *Arve*, in *Natural History*, a fruit contained within a smooth but hard bark, including a single seed; its hind-part being covered with a kind of cup, and the fore-part bare. See **ACORN** and **OAK**.

GLANS, in *Anatomy*, the tip or button of the **PENIS**, or that part covered with the prepuce, called also *balanus*. See **Tub. Anat.** (*Silvanus*) fig. 10. lit. d. fig. 15. lit. a. The *glans* is only a dilatation of the extremity of the spongy substance of the urethra, which is here bunched, and turned back to the two conical tips of the corpora cavernosa, which terminate therein.

The extremity of the prepuce is apt to grow so tight in old men, that they cannot bare the *glans*; perhaps through the defect of frequent erections.

We read of a *glans penis* regenerated after amputation, in the *Mémoires de l'Académie* vol. v. art. 35.

GLANS is also used to denote the tip or extremity of the **CLITORIS**, from its resemblance, both in form and use, to that of the penis. See **Tub. Anat.** (*Silvanus*) fig. 15. lit. c.

The principal difference consists in this, that it is not perforated. This *glans* is also covered with a prepuce, formed of the inner membrane of the labia.

GLANS murina, in *Natural History*, a name given to a genus of shell-fish, more usually called **BALANUS**, and in English the *centre-shell*.

GLANS trachelifera, in *Natural History*, a name given by Geiser, and some other writers, to a kind of figured fossil, found usually among the tracheæ and entrochi, and evidently appearing to have in some manner belonged to them. All the writers, who have themselves examined the places where the tracheæ are found, have mentioned these under the names of *glans trachelifera*, others under less determinate ones. Agricola calls them *lapides inferiores*, and Lister, after him, *radii pueri*, having impressions of the entrochi. See father Philo. Trans. N° 100.

GLANUS, or **GLANTS**, in *Idiopathy, a name given by Pliny, and many other of the old writers, to that species of the fluvius which we in English call the *shear-fish*, the *glans* and *silurus* of authors, distinguished by Aristotle by the name of the fluvius with four boards on the chin.*

GLAREANA, in *Ornithology*, the name of a bird described by Geiser from the figure, and suspected to be no way different from the **SPICULETTA**, called *turdus* by the Venetians, a kind of *lark*.

GLASS vitrum, a transparent, solid, brittle, facillious body, produced of a salt and sand, or stone, by the action of fire.

The word is formed of the Latin *glazum*, a plant called by the Greeks, *glazi*; by the Romans, *vitrum*; by the ancient Britons, *gladum*; by the English, **WAD**. We find frequent mention of this plant in ancient writers, particularly Cæsar, Vitruvius, Pliny, &c. who relate, that the ancient Britons painted or dyed their bodies with *glazum*, *gladum*, *vitrum*, &c. i. e. with the blue colour procured from this plant. And hence the facillious matter we are speaking of, came to be called *glazi*, as having always somewhat of this blueness in it.

The chemists hold that there is no body but may be vitrified, i. e. converted into *glazi*. By intense heat, even gold itself gives way to the sun's rays collected in a burning-glass, and becomes *glazi*.

Add, that as *glazi* is the effect or fruit of fire, so it is the last effect of that element; all the chemists agree, and all the force of fire not being able to carry the change of any natural body beyond its **VITRIFICATION**.

GLASS, nature and characters of. Naturalists are divided in what class of bodies to rank *glazi*. Agricola considers it as a concrete juice; Bellorocensis, as a stone; Fallopius ranks it among the *media mineralia*; and the workmen, when in fusion, call it metal: but Dr. Meier, with reason, sets aside all these opinions; from this consideration, that all the forementioned bodies are natural concretes; whereas *glazi* is a compound made by art, and is never found in the earth as the others.

Fallopius,

Fallopian, indeed, contends, that *glaf* is no more artificial than a metal, and that they are both equally extracted or educed from other bodies; the one from sand, the other from its ore. He adds, that though salts or ashes be added to sand for the making of *glaf*, yet it is false that they contribute to the composition of *glaf*; their use, according to him, being only for the better extracting of the *glaf* from the mineral stone.

This Dr. Merret easily confutes: for if *glaf* were extracted from stones or sand only, the weight of the metal must be much less than that of the stones alone; whereas it is, in reality, much greater, a hundred weight of sand sufficing for one hundred and fifty of *glaf*.

In effect, the ashes contribute a deal of salt to the composition of *glaf*. Accordingly, in pieces of old *glaf* one may sometimes pick out grains of salt, easily discoverable to the taste; beside that the finest *glaf*, standing long in a subterraneous place, will moulder or resolve into its first ingredients, salt and sand, by the decay of the union thereof: whence it appears, that the salt remains in the *glaf* in specie. To which may be added that experiment of Van Helmont: "Melt *glaf*-dust with sandifer, and set them in a moist place, and the *glaf* will resolve into water; pour on aqua regia, enough to saturate the sandifer, and the sand will precipitate to the bottom in the same quantity and weight as was first used." Helm. cap. De Terra.

Here, then, is a true analysis of *glaf*, or a solution into its first principle or ingredients, the salt being imbibed by the sandifer and aqua regia. Merret. Not. in Ant. Neri De Art. Vitræ.

The learned and curious author just mentioned gives us the following characters or properties of *glaf*, whereby it is distinguished from all other bodies, viz. 1. That it is an artificial concrete of salt and sand, or stones. 2. Fusible by a strong fire. 3. When fused, tenacious and coherent. 4. It does not waste or consume in the fire. 5. When melted, it cleaves to iron. 6. Ductile, when red-hot, and fashions into any form, but not malleable; and capable of being blown into a hollowness, which no mineral is. 7. Frangible, when thin, without annealing. 8. Friable when cold. 9. Always diaphanous, whether hot or cold. 10. Flexible and elastic. 11. Dissoluble by cold and moisture. 12. Only capable of being graven, or cut with a diamond or other hard stones, and emery. 13. Receives any colour or dye both externally and internally. 14. Not dissolvable by aqua fortis, aqua regia, or mercury. 15. Neither acid juices, nor any other matter, extract either colour, taste, or any other quality, from it. 16. It admits of polishing. 17. Neither loses of weight nor substance, by the longest and most frequent use. 18. Gives fusion to other metals, and softens them. 19. The most pliable thing in the world, and that which best retains the fashion given it. 20. Not capable of being calcined. 21. An open *glaf*, filled with water in the summer-time, will gather drops of water on the outside, just so far as the water on the inside reaches; and a man's breath blown upon it will manifestly moisten it. 22. Little *glaf* balls, filled with water, mercury, or other liquor, and thrown into the fire, as also drops of green *glaf* broken, fly asunder with a loud noise. 23. Neither wine, beer, nor any other liquor, will make it muddy, nor change its colour, nor rust it. 24. It may be cemented as stones and metals. 25. A drinking-*glaf*, partly filled with water, and rubbed on the brim with a wet finger, yields musical notes, higher or lower, as the *glaf* is more or less full; and this makes the liquor frisk and leap.

GLASS, ductility of. See DUCTILITY.

GLASS, origin and history of. De Neri will have *glaf* as ancient as Job; for that writer, chap. xxviii. ver. 17. speaking of wisdom, says, Gold and *glaf* shall not be equalled to it.

This, we are to observe, is the reading of the Septuagint, Vulgate Latin, St. Jerom, Pineda, &c. for in the English version, instead of *glaf*, we read *crystal*; and the same is done in the Chaldean, Arias Montanus, and the same of Spain's edition. In other versions, &c. it is read *stone* in others, *beryl*: in the Italian, Spanish, French, High and Low Dutch, &c. *diamond*: in others, *turquoise*; and in the Targum, *looking-glass*.

In effect, the original word is *sechumsh*, which is derived from the root *sham*, to purify, cleanse, shine, be white, transparent: and the same word, Exod. xxx. 34. is applied to frankincense; and rendered in the Septuagint, *gallula*. Hence the reason of so many different renderings; for the word signifying beautiful and transparent, in the general, the translators were at liberty to apply it to whatever was valuable and transparent.

Most authors will have Aristophanes to be the first author who mentions *glaf*: that poet, in his comedy called the Clouds, scene i. act ii. uses the word *hulan*, *hulan*, Vol. II. N° 152.

which is now ordinarily rendered *glaf*. He there introduces Strepsiades, teaching Socrates a new way to pay old debts, viz. "by placing a fair transparent stone, sold by the druggist, from which the fire is struck, between the sun and the writing, and so melting away the letters thereof." This stone Socrates calls *hulan*, which the scholiast on Aristophanes derives from *hul*, to melt, from the likeness it bears to ice, which is rain, or water congealed; though, it must be owned, the word *hulan* is ambiguous, and signifies crystal as well as *glaf*; and Corneus observes, that the ancients had a kind of yellow amber, transparent as *glaf*, called by some *hulan*.

Aristotle has two problems upon *glaf*: the first, Why we see through it? The second, Why it is not malleable? If these problems be Aristotle's, which the learned doubt very much, this would probably be the earliest testimony in favour of the antiquity of *glaf*; but the first author, who makes unquestionable mention of this matter, is Alexander Aphrodisius, who uses it in a simile: "As the floridness of a colour is seen through *glaf*," &c.

After him the word occurs commonly enough: Lucian mentions large drinking-*glaf*s; and Plutarch, in his Symposiaca, says, that the fire of tamarisk-wood is the finest for the making of *glaf*.

Among the Latin writers, Lucretius is the first that takes notice of *glaf*. *Nihil rectius formam transant, Quam sua vitæ*. Dr. Merret, however, adds, that *glaf* could not be unknown to the ancients, but that it must needs be as ancient as pottery itself, or the art of making bricks; for scarcely can a kiln of bricks be burnt, or a batch of pottery ware be made, but some of the bricks and ware will be at least superficially turned to *glaf*. Hence, Ferrant. Imperialis, lib. xxi. cap. 7. "Glaf," like the common kind, is found under ground, in places where great fires have been. Other *glaf*s are found in round cloths, like fire-stones, some brittle, others firm, &c. This soft *glaf* is wrought by the Americans, and used instead of iron."

And no doubt but vitrifications were more common in the ancient bricks than they are in ours; as they tempered their earth two years together, and burnt them better.

Pliny relates the manner of the discovery of *glaf*. It was found, according to that author, by accident, in Syria, at the mouth of the river Belos, by certain merchants driven thither by the famine of the sea. Being obliged to live there, and dress their victuals by making a fire on the ground, and there being flore of the plant kali upon the spot, this herb being burnt to ashes, and the sand or stones of the place accidentally mixed with it, a vitrification was undesignedly made; from whence the hint was taken, and easily improved.

Indeed, how old forever *glaf* may be, the art of making and working it appears of no great antiquity. The first place mentioned for the making hereof, is Sidon in Syria, which was famous for *glaf* and *glaf*-houses, as observed by Pliny, lib. xxxvi. cap. 26. § 66. Mr. Nixon, in his observations on a plate of *glaf*, found at Hierusalem, which was destroyed A. D. 80, on which occasion Pliny lost his life, offers several probable conjectures as to the uses to which such plates might be applied.

Such plates, he supposes, might serve for *specula*, or looking-*glaf*s; for Pliny, in speaking of Sidon, adds, *quidam etiam specula excoquebant*: the reflection of images from these ancient *specula* being effected by beaming them behind, or tinging them through with some dark colour. Another use in which they might be employed, was for adorning the walls of their apartments, by way of windows, to which Pliny is supposed to refer by his *vitrea camera*, lib. xxxvi. cap. 25. § 64. Mr. Nixon further conjectures, that these *glaf* plates might be used for windows, as well as the lamina of lapis specularis and phengites, which were improvements in luxury mentioned by Seneca, and introduced in his time, Ep. xc. However, there is no positive authority relating to the usage of *glaf*-windows earlier than the close of the third century: *Manilius est*, says Lactantius, *mentem esse, quæ per vitæ in sua sunt opposita, transpicit, quasi per specula lucens vitæ aut speculæ lapide obtundit*. De Opticis Del. cap. 5. See Phil. Trans. vol. I. art. 80. p. 601. vol. iiii. art. 23. p. 123.

The first time we hear of *glaf* made among the Romans was in the time of Tiberius, when Pliny relates, that an artist had his house demolished for making *glaf* malleable, or rather flexible; though Petronius Arbiter, and some others, assure us, that the emperor ordered the artist to be beheaded for his invention.

According to venerable Bede, artificers killed in making *glaf* were brought over into England, in the year 674, by

by abbot Benedick, who were employed in glazing the church and monastery of Wexmouth. According to others, they were first brought over by Wilfrid, bishop of Worcester, about the same time. Till this time the art of making glass was unknown in Britain; though glass windows did not begin to be used before the year 1180: till this period they were very scarce in private houses, and considered as a kind of luxury, and as marks of great magnificence. Italy had them first, next France, from whence they came into England.

Venice, for many years, excelled all Europe in the fineness of its glass; and in the thirteenth century, the Venetians were the only people that had the secret of making crystal looking-glasses. The great glass-works were at Muran, or Murano, a village near the city, which furnished all Europe with the finest and largest glasses.

The glass manufacture was first begun in England in 1557: the first furnace was made in the place called Crutched Friars, in London; the fine flint glass, little inferior to that of Venice, was first made in the Savoy-house, in the Strand, London. This manufacture appears to have been much improved in 1635, when it was carried on with sea-coal or pit-coal, instead of wood, and a monopoly was granted to Sir Robert Mansell, who was allowed to import the fine Venetian flint glasses for drinking, the art of making which was not brought to perfection before the reign of William III. But the first glass-plates, for looking-glasses, and coach windows, were made in 1673, at Lambeth, by the encouragement of the duke of Buckingham; who, in 1676, introduced the manufacture of fine glass into England, by means of Venetian artists, with amazing success. So that within a century past, the French and English have not only come up to, but even surpassed the Venetians, and we are now no longer supplied from abroad.

The French made a considerable improvement in the art of glass, by the invention of a method to cut very large plates, till then unknown, and scarce practised yet by any but themselves and the English.

That court applied itself with a laudable industry to cultivate and improve the glass manufacture. A company of glass-men was established by letters patent; and it was provided by an act, not only that the working in glass should not derogate any thing from nobility, but even that none but nobles should be allowed to work therein.

GLASS, ingredients of. The materials used in the composition of glass, we have observed, are sand and, or else some kind of stone.

The sand is of the fixed kind, such as will not evaporate with the most intense heat: the sand or stone must be such as will melt easily; this is what gives firmness and consistency to the glass.

1. This salt is procured chiefly from a kind of ashes, called *POLYMERINE*, or *volcanica*, brought from the Levant, and particularly from Alexandria and Tripoly. The ashes are those of a vegetable, frequent in the country, commonly called *KALI*, sometimes *KALI, KALU, KALI*; by Gesner, *alkali*; by Lobel, *felds*; by Dodonæus, *felds*; and by Camer, Gordofus, Fuchsius, &c. *anthylli*. Dr. Merret calls it *English salt-wort*, from its saline taste; and *glass-wort*, from the use made of its ashes in making of glass.

Baubin mentions ten species of this plant, whereof there are four used by the Alexandrians, &c. for the making of polymerine and soap, viz. *kali granulatum*, *kali secundum speciem*, *kali hypericum*, and *kali spinosum*.

The first and last our own coasts afford, where they are called by the people *frag-grass* and *sea-grass*; but they are of no use for making of glass: being laid on a hot iron, they fly off almost wholly in fumes, leaving almost no ashes at all; whereas the *kali* brought from the Levant, applied on the same iron, are soon converted almost wholly into polymerine, i. e. very saline ashes of a dark colour.

To get this salt from the polymerine, they pulverize and sift it very fine; then boil it in a bras copper, with fair water and tartar, till a third part of the water is consumed, taking care to stir it from time to time; then, filling up the copper with fresh water, they boil it a second time, till half be consumed: this done, they have a ley impregnated with salt. To get the salt from the ley, they boil them till the salt shoots at the top, which they scum off as it rises into earthen pans, and thence into wooden vats to drain and dry.

When the salt is dry, they beat it grossly, and put it into a furnace, to dry it farther with a gentle heat. When it is made sufficiently dry, they pound and sift it very fine, and lay it by to make *tert.*

Note, Instead of the ashes of the plant *kali*, those of fern will also yield a salt which makes excellent glass, nothing inferior to that of polymerine: the method of pro-

paration is the same. Add, that the ashes of the cuds and stalks of beans, as also those of coleworts, bramble-bush, millet stalks, rushes, cyperuses, and many other plants, may be used for the like purpose, and after the same manner.

Pearl-shells form a leading flux in the manufacture of glass, and mostly supply the place of the *Levantines*, the barilla of Spain, and many other kinds, which were formerly brought here for making both glass and soap. See *PEARL-SHELL*.

There are other fluxes used for different kinds of glass, and for various purposes, as calcined lead, nitre, sea-salt, borax, arsenic, smiths clinkers, and woodashes, containing the earth and lixivious salt, as produced by incineration. With regard to these several fluxes, we may observe, in general, that the more calx of lead, or other metallic earth enters into the composition of any glass, so much the more fusible, soft, coloured, and dense this glass is, and reciprocally.

The colours given to glass by calxes of lead, are shades of yellow: on the other hand, glasses that contain only saline fluxes partake of the properties of salts; they are less heavy, less dense, harder, whiter, more brilliant, and more brittle than the former; and glasses containing both saline and metallic fluxes, do also partake of the properties of both these substances. Glasses too saline are easily susceptible of alteration by the action of air and water; especially those in which alkalis prevail; and these are also liable to be injured by acids. Those that contain too much borax and arsenic, though at first they appear very beautiful, quickly tarnish and become opaque when exposed to air. By attending to these properties of different fluxes, phlogistic or saline, the artist may know how to adjust the proportions of these to sand, or powdered flints, for the various kinds of glass. If a glass be required that is dense, fusible, and not saline, one part and a half of red lead or litharge may be mixed with one part of sand, and fused together: if equal parts of sand and of calx of lead be employed, a glass somewhat less dense and harder will be produced: if a glass be required of very little density, only saline fluxes must be employed. A glass of this kind may be composed of six parts of salt of tartar, or of pot-ash, or of purified soda, mixed with eight parts of sand or of flints; or of four parts of any of the above mentioned alkalis, mixed with two parts of nitre, or of borax, and eight parts of vitrifiable earth. When a crystal glass is required, which shall be of an intermediate quality betwixt the metallic and saline glasses, it may be made from a mixture of one part of the above mentioned salts, one part of calx of lead, and two parts of sand or other vitrifiable earth.

By varying the proportion of these ingredients, many different kinds of glasses may be produced, each of which may be good, if the quantity of each of the fluxes employed be proportionable to its vitrifying power. Dict. Chem. art. *Vitrification*.

2. For stone, the second ingredient in glass. The best, we have observed, is that which will melt, is white, and transparent: This is found principally in Italy, being a sort of stony substance, called *terre*: the next is *pierre*, or *coquage*, a sort of pebbles found at the bottoms of rivers, and gathered for the Venetian manufacture out of the river Po, which are said not to be inferior in whiteness to alabaster.

Indeed, nothing makes finer and clearer glass than common flint, distinguished by this use for their clear, transparent, black colour: but the charge of preparing it detests the glass-men from using it. The preparation necessary for stone is to calcine, powder, and sieve it.

Ant. Neri observes, that all white transparent stones, which will not burn to lime, are fit to make glass; and that all stones which will strike fire with steel, are capable of being employed in making of glass. But this latter rule, Dr. Merret observes, does not hold universally.

Where proper stone cannot be had, sand is used; and it is now almost the only kind of substance employed in the British manufacture of glass. The best for this purpose is that which is white, small, and shining; examined by the microscope, it appears to be small fragments of rock crystal. For green glass, that which is of a soft texture, and more gritty, it is to be well washed, which is the preparation it needs. Our glass-houses are supplied with white sand for their crystal glasses from the Downs, Norfolk, and Maidstone in Kent; and with the coarser for green glass, from Woolwich.

Some mention a third ingredient in glass, viz. *Manganese*, or *MAGNETA*, or *pyrolite*, a kind of pseudo-metallic stone, dug up in Germany, Italy, and even in the hills in Somersetshire. But the proportion hereof is other is very inconsiderable; besides that it is not of all glasses. Its office is to purge off the natural green colour and give it some other tincture required.

For this purpose it should be chosen of a deep colour, and free from specks of a metalline appearance, or a lighter cast; magnesia requires to be well calcined in a hot furnace, and then to undergo a thorough leavison. The effect of magnesia in destroying the colours of *glass*, and hence called the soap of *glass*, is accounted for by M. Montanmy, in his *Traité des Couleurs pour la Peinture* in the following manner: the magnesia destroys the green, olive, and blue colours of *glass*, by adding to them a purple tinge, and by the mixture produces a blackish brown colour; and, as blackness is caused by an absorption of the rays of light, the blackish colour given to the *glass* by the mixture of colours, prevents the reflection of so many rays, and thus renders the *glass* less coloured than before. But the black produced by this substance suggests an obvious reason for using it very sparingly in those compositions of *glass*, which are required to be very transparent. Nitre or salt-petre is also used with the same intention, for by destroying, in a certain degree, the phlogiston, which gives a strong tinge of yellow to *glass* prepared with lead as a flux, it serves to free it from this coloured tinge; and in saline *glass*, nitre is requisite in a smaller proportion to render them sufficiently transparent, as in the case of looking-*glass*, and other kinds of plates. For an account of Mr. Dollond's excellent contrivance for destroying the colours in the object glasses of telescopes, &c. see ABERRATION.

After all, the most transparent *glass* is subject to bubbles and veins, the method of preventing which are yet little known; and this is an inconvenience by which Mr. Dollond's excellent discovery is affected; for the flint *glass*, which he uses, is peculiarly subject to small veins, that disturb the rays in their passage, and render the vision confused. This effect is owing to the density of these veins being greater than that of the rest of the *glass*, as appears from their image received on white paper, when the *glass* is held between the paper and a candle, or other luminous object; for this image of a vein, thus received, is a line brighter than the rest of the image of the *glass*, and this bright line is defined by a dark edge on each side. But the bright line evidently shews a convergence of rays, which can only be effected by the veins being denser than the medium in which they are placed. The reason why flint *glass* is more subject to veins than any other *glass* is, says the translator of Macquer's Chemical Dictionary, because it is composed of materials of more different densities.

M. Macquer, with a view of improving the manufacture of this *glass*, proposes to facilitate the union of the calx of lead and sand, of which it is composed, by depriving the calx of lead, as much as possible, of its phlogiston, which may be done by combining the vitriolic acid with minium, or red-lead, and exposing this composition to the operation of fire, to disengage it from the acid, and also by giving these two substances the greatest possible degrees of fluidity and mobility, which may be done by mixing with the composition of them a considerable quantity of solvents. Hill Acad. Scienc. for 1773. As impenetrable as *glass* is to the common menstruums, we find it eaten by the air in length of time, when exposed in old windows; but the effects of its being kept in a subterraneous place are much more strange. Borrichius tells us, that at the time when he was at Rome, there was dug up a whole house from under the kitchen garden of a citizen. The house had been buried there ten ages, and there were found in it several glass urns, or isothermatories. The *glass* of these had no holes made in it, as our old *glass* in chamber-windows has, but still retained its smooth surface and transparency; but it was split into a vast number of thin laminae, which were as pellucid and fine as bluey *glass*; and in some places were tinged with all the beautiful colours that art could have given. We are not acquainted perfectly with the ancient way of working their *glass*; but it is not probable there could be any thing particular in the formation of the vessel, to determine it to split thus into flakes; but that *glass* of the same kind, in any form, would have done the same. Borrich. De Orig. Chemic.

GLASS, kinds of. The manufactured *glass* now in use may be divided into three general kinds; white transparent *glass*, coloured *glass*, and common green or bottle *glass*. Of the first kind, there is a great variety; as the flint *glass*, as it is called with us, and the German crystal *glass*, which are applied to the same uses; the *glass* for plates for mirrors or looking-*glass*; the *glass* for windows and other lights; and the *glass* for phials and small vessels. And these again differ in the substances employed as fluxes in forming them, as well as in the coarseness or fineness of such as are used for their body. The flint and crystal, mirror and best window *glass*, not only require such purity in the fluxes, as may render it prac-

ticable to free the *glass* perfectly from all colour; but for the same reason likewise, either the white Lynn sand, calcined flint, or white pebbles, should be used. The others do not demand the same purity in the choice of the materials; though the second kind of window *glass*, and the best kind of phial, will not be so clear as they ought, if either too brown sand, or impure salts, be suffered to enter into their composition.

Of coloured *glass* there is a great variety of sorts, differing in their colour, or other properties, according to the occasions for which they are wanted. The differences in the latter kind depend on the accidental preparation and management of the artist by whom they are manufactured. See the subsequent articles.

GLASS, instruments for manufacturing. These are subservient to two different purposes; viz. the levigation and mixture of the ingredients, and the fusion or vitrification of them. To the former class belong horse or hand-mills, mortars and pestles, flat stones and mullars, and searers or sieves. The other sort of utensils are furnaces, with the proper iron work, pots for containing the composition when put into the fire, and iron instruments for shifting the matter out of one into the other, in case of accidents; and for taking out small portions, in order to judge of the progress of the vitrification, and the qualities of the *glass*, &c. See the following articles.

GLASS, method of making white and crystal. There are three sorts of furnaces used in the *glass*-works: one to prepare the frit, called the calcar; a second, to work the *glass*; and a third, called the *lev*, to anneal it. See them all described under the article FURNACE.

To make crystal *glass*, take of the whitest *turf*, pounded small, and sieved as fine as flour, two hundred pounds; of the salt of potteries, a hundred and thirty pounds; mix them together, and put them into the furnace, called the calcar, first heating it. For an hour keep a moderate fire, and keep stirring the materials with a proper rake, that they may incorporate and calcine together; then increase the fire for five hours; after which take out the matter; which, being now sufficiently calcined, is called FRIT. From the calcar put the frit in a dry place, and cover it up from the dust for three or four months.

Now, to make the *glass*, or crystal: take of this crystal frit, called also *levin*; put it in pots in the furnace, adding to it a due quantity of magnesia, or manganese: when the two are fused, call the flux into fair water, to clear it of the salt, called *insoluble*, which would otherwise make the crystal obscure and cloudy. This lesson must be repeated again and again, as often as needed, till the crystal be fully purged; or, this lesson may be taken off by means of proper ladles. Then let it to boil four, five, or six days; which done, see whether it have manganese enough; and if it be yet greenish, add more manganese, at discretion, by little and little at a time, taking care not to overdo it, because the manganese inclines it to a blackish hue. Then let the metal clarify, till it becomes of a clear and shining colour; which done, it is fit to be blown, or formed into vessels at pleasure.

GLASS, flint, as it is called in our country, is of the same general kind with that which in other places is called crystal *glass*. It has this name from being originally made with calcined flint, before the use of the white sand was understood; and retains the name, though now flints are now used in the composition of it. This flint *glass* differs from the other, in having lead for its flux, and white sand for its body; whereas the fluxes used for the crystal *glass* are salts or arsenic, and the body consists of calcined flints, or white river pebbles, *turf*, or such stones. To the white sand and lead a proper proportion of nitre is added, to burn away the phlogiston of the lead, and also a small quantity of magnesia; and in some works they use a proportional quantity of arsenic to aid the fluxing ingredients. The most perfect kind of flint *glass* may be made by fusing with a very strong fire a hundred and twenty pounds of the white sand, fifty pounds of red lead, forty pounds of the best pearl-ashes, twenty pounds of nitre, and five ounces of magnesia. Another composition of flint *glass*, which is said to come nearer to the kind now made, is the following: a hundred and twenty pounds of sand, fifty four pounds of the best pearl-ashes, thirty-six pounds of red-lead, twelve pounds of nitre, and six ounces of magnesia. To either of these a pound or two of arsenic may be added, to increase the flux of the composition. A cheaper composition of flint *glass* may be made with a hundred and twenty pounds of white sand, thirty-five pounds of the best pearl-ashes, forty pounds of red lead, thirteen pounds of nitre, six pounds of arsenic, and four ounces of magnesia; or, instead of the arsenic, may be substituted fifteen pounds of common salt; but this will be more brittle than the other. The cheapest composition for the work kind of flint *glass* consists of a hundred and twenty pounds

pounds of white sand, thirty pounds of red-lead, twenty pounds of the best pearl-ashes, ten pounds of nitre, fifteen pounds of common salt, and six pounds of arsenic. The best German crystal glass is made of a hundred and twenty pounds of calcined flint, or white sand, seventy pounds of the best pearl-ashes, ten pounds of salt-petre, half a pound of arsenic, and five ounces of magnesia. And a cheaper composition is formed of a hundred and twenty pounds of calcined flint or white sand, forty-six pounds of pearl-ashes, seven pounds of nitre, six pounds of arsenic, and five ounces of magnesia.

A glass much harder than any prepared in the common way, may be made by means of borax in the following method: take four ounces of borax, and an ounce of fine sand; reduce both to a subtil powder, and melt them together in a large close crucible set in a wind-furnace, keeping up a strong fire for half an hour; then take out the crucible, and when cold break it, and there will be found at the bottom a pure hard glass, capable of cutting common glass like a diamond. This experiment, duly varied, may lead to several useful improvements in the art of glass, enamels, and facitious gems, and thence an expeditious method of making glass, without any fixed alkali, which has been generally thought an essential ingredient in glass, and it is not yet known whether calcined crystal, or other substances, being added to this salt instead of sand, it might not make a glass approaching to the nature of a diamond. Shaw's Lectures, p. 426.

There are three principal kinds of glasses, distinguished by the form or manner of working them, viz. round glass, as those of our vessels, phials, drinking glasses, &c. table or window-glass, of which there are several kinds, viz. crown-glass, plate-glass, &c. and plate-glass, or looking-glass.

GLASS, working or blowing round. The working furnace we have observed, is round, and has six bocas, or apertures: at one of these, called the *great boca*, the furnace is heated, and the pots of fire are at this set in the furnace; two other smaller holes, called *accarellas*, serve to take out the melted metal, at the end of an iron, to work the glass. At the other holes they put in pots of fusible ingredients, to be prepared, and at last emptied into the ladling pot.

There are six pots in each furnace, all made of tobacco-pipe clay, proper to sustain not only the heat of the fire, but also the effect of the polymerine, which penetrates every thing else. There are only two of these pots that work: the rest serve to prepare the matter for them. The fire of the furnace is made and kept up with dry hard wood, cut in, without intermission, at six apertures.

When the matter, contained in the two pots, is sufficiently vitrified, they proceed to blow or fashion it: the process whereof we shall here deliver from Agricola, Dr. Merret, the French Diction. de Commerce, &c.

The operator, or fervitor (the vessel being now sufficiently refined), takes his blowing iron, which is a hollow tube, about two feet and a half long; and dipping it in the melting pot, there turns it about: the metal thickens to the iron like some glutinous, or clammy juice; much like, but more firmly than turpentine, or honey.

For each glass he dips four times, and at each dip rolls the end of his instrument, with the glass thereon, on a piece of iron, over which is a vessel of water; the coolness whereof helps to consolidate the glass more readily, and disposes it the better to bind with the next to be taken out of the pot.

After they have dipped a fourth time, and when there is now matter enough on the instrument, the operator begins to blow gently through the iron, by which he raises or lengthens it nearly a foot; much as we do by blowing in a bladder, or globe; and to give it a polish, he rolls it to and fro on a stone, or marble.

This done, he blows a second time, and thus forms the bunch, or belly of the glass. The matter, by this second blast, assumes the figure of a gourd, or calabash, eighteen or twenty inches in diameter. As often as the operator blows into the iron (which must be very often), he removes it hastily from his mouth to his cheek, lest he should draw the flame into his mouth, when he re-appears it to the iron.

The operator whirls his iron many times round his head, to lengthen and cool the glass; sometimes the glass, thus blown round, is returned to the fire, where it flattens a little of itself: when flattened, it is again taken out, and cooled; and, if needful for the design, the workman flats its bottom, by pressing it on the marble, or moulds it in the stamp-irons; and thus delivers it to the master-workman, to break off the collet.

The collet, or neck, is the narrow part which cleaves to the iron: to set the glass at liberty, they lay a drop of cold

water on the collet; which, by its coldness, cuts or cracks about a quarter of an inch: after which, giving it a slight blow, the fracture is communicated all around the collet. The waste piece is thrown by to make green glass.

This done, they dip an iron rod, or ponteggio, in the melting-pots; and with the matter that sticks thereto, they apply and flatten it to the bottom of the vessel opposite to the collet. The vessel, thus sustained by the iron rod, is carried to the great boca to be blown and cooled; and while another person takes out the rod, the fervitor operator rests, and prepares himself for the blowing.

To branch, or make the bowl, they thrust in an iron instrument, called the *passage*; and the aperture, opened thereby, they further augment, and widen with the *pre-celle*: in turning this instrument about, to form the bowl, the edge becomes thickened; the glass being, as it were, doubled in that part; whence the hem observed on the circumference of our glasses. What is superfluous, they cut off with the shears.

The vessel, thus opened, is returned to the great boca; where being sufficiently heated a second time, the workman gives the bowl its finishing, by turning it about with a circular motion; which it increases, in proportion as the bowl opens, and enlarges by means of the heat and agitation.

The glass thus finished, they carry it from the boca, still turning it round, to a kind of earthen bench, covered with brands, or coals extinguished: here they let it cool a little, and come to its consistence, having first detached it from the iron rod by a stroke or two with the hand.

Thus, with blowing, pressing, scalding, amplifying, and cutting, the glass is framed into the shape preconceived in the workman's mind. If need be, he proceeds to put on a foot and handle, or any other decoration.

When the master has finished a number of these, another fervitor takes them with an iron fork, and specially places them in the tower, or rack, to anneal and harden.

What has been here said of white, or crystal glass, holds equally of common, or green glass, the working being the same in all; and the difference only in the salt, or polymerine, made use of.

So many matters as there are, so many pots at the least, and so many bocas there must be; each man having his proper station: where, says Dr. Merret, they receive those scorching heats falling directly into their faces, mouths, and lungs; whence they are forced always to work in their shirts, like the Cyclopes, and nudimembra Pyracmones, with a straw broad-brimmed hat on their heads, to defend their eyes from the excessive heat and light. They sit in large, wide, and wooden chairs, with two long elbows, to which their instruments are hung. They work six hours at a time, measured by a single glass; after which they are relieved by others, for the like time; so that the furnaces are never idle.

Working, or blowing windows, or table GLASS. The method of making crown window-glass, now practised in England, is said to have been borrowed from the French. An English glass maker went over to work in France, on purpose to get into the secret; which when he had attained to, he returned, and set up a glass-work, wherein he far outdid the French, his teachers.

This glass is blown much after the manner of looking-glass. Some writers, from wrong intelligence, have said that it was run, or cast in sand; but the real process is as follows:

The furnace, melting-pots, materials, and fire, are the same for window, or table-glass, as they are for round glass; and the difference in the operation only commences after the fervitor has dipped his blowing iron the fourth time in the melted metal.

The glass then being in this condition, they blow it; but instead of rounding, or forming it into a bunch, the particular motion the workman gives it in the directing and managing the wind, and the way of rolling it on the iron, make it extend in length two or three feet, and form a cylinder, which at first is but two inches in diameter; but which, by being recommended to the fire, and blown afresh when taken out, becomes of the extent required for the table of glass to be formed with this circumstance, however, that the side which is flattened to the iron, goes gradually diminishing, and ends in a kind of cone or pyramid.

To render the two ends nearly of the same diameter, after adding a little glass to that opposite to the iron, they draw it out with a pair of iron pinchers. Then they cut off the same end with a little water; and carrying this cylinder back to the boca, they cut it likewise with water in two other places; one place being at the distance of eight or ten inches from the iron, and the other through the whole length.

The *glass cylinder*, thus abridged of both its extremities, is next heated on a kind of earthen table, somewhat raised in the middle, in order to promote its opening at the place cut longitudinally. The workman here makes use of an iron, wherewith he alternately lowers and raises the two sides, or halves of the cylinder, which now begin to open, and unfold like a sheet of paper, which at length grows perfectly flat. The table of glass is now in its full open shape, and needs nothing further but to be heated over again. When taken out, they lay it on a table of copper, whence, after it has cooled, and come to its consistence, they carry it on forks to the tower of the furnace, where they leave it to anneal for twenty-four hours.

The number of tables annealed at a time, which sometimes amount to a hundred, or more, with the perpendicular situation they are set in, occasioned, anciently, that those set in first, sustaining, in some measure, the pressure of the last, were bent, and thus rendered inconvenient for use; but this inconvenience is now remedied, by separating them into tens, with an iron filver; which, diminishing the weight, by dividing it, keeps the tables as flat and even as they were put in.

GLASS, kinds of table or window. There are divers sorts of this glass made in divers places, for the use of building, those most known among us, are given us by the author of the Builder's Dictionary, as follows.

GLASS, crown, of which, says Neve, there are two kinds, distinguished by the places where they are wrought; viz. 1. *Ratcliff crown glass*, which is the best and clearest, and was first made at the Boat-garden, on the Bank-side, Southwark, but since at Ratcliff: of this there are twenty-four TABLES to the CASE, the tables being of a circular form, about three feet six inches in diameter.

2. *Lambeth crown glass*, which is of a darker colour than the former, and more inclining to green.

The best window, or crown glass, is made of white sand, sixty pounds; of purified pearl ashes, thirty pounds; of salt-petre, fifteen pounds; of borax one pound; and of arsenic, half a pound. If the glass should prove yellow, magnesia must be added. A cheaper composition for window glass consists of sixty pounds of white sand, twenty-five pounds of unpurified pearl-ashes, ten pounds of common salt, five pounds of nitre, two pounds of arsenic, and one ounce and a half of magnesia. The common or green window glass, is composed of sixty pounds of white sand, thirty pounds of unpurified pearl-ashes, ten pounds of common salt, two pounds of arsenic, and two ounces of magnesia. But a cheaper composition for this purpose, consists of a hundred and twenty pounds of the cheapest white sand, thirty pounds of unpurified pearl-ashes, sixty pounds of wood ashes, well burnt and sifted, twenty pounds of common salt, and five pounds of arsenic.

GLASS, French, as also called *Normandy glass*, and formerly *Lorraine glass*, because made in those provinces: at present it is made wholly in the nine glass works; five whereof are in the forest of Lyons, four in the county of Euz; the last at Beaumont, near Rouen. It is of a thinner kind than our crown glass; and when laid on a piece of white paper, appears of a dirtyish green colour. There are but twenty-five TABLES of this to the CASE.

GLASS, German, is of two kinds, the white and the green the first is of a whitish colour, but is subject to those small curved streaks, observed in our Newcastle glass, though free from the spots and blemishes thereof. The green, besides its colour, is liable to the same streaks as the white; but both of them are flatter, and less warped, than our Newcastle glass.

GLASS, Dutch, is not much unlike our Newcastle glass, either in colour or price. It is frequently much warped, like that; and the tables are but small.

GLASS, Newcastle, is that most used in England. It is of an ash colour, and much subject to specks, streaks and other blemishes; and, besides, is frequently warped. Leybourn says, there are forty-five tables to the case, each containing five superficial feet: some say there are but thirty-five tables, and six feet in each table.

GLASS, phial, is a kind of glass betwixt the flint glass and the common bottle, or green glass. The best kind may be prepared with a hundred and twenty pounds of white sand, fifty pounds of unpurified pearl-ashes, ten pounds of common salt, five pounds of arsenic, and five ounces of magnesia. The composition for green or common phial glass, consists of a hundred and twenty pounds of the cheapest white sand, eighty pounds of wood-ashes, well burnt and sifted, twenty pounds of pearl-ashes, fifteen pounds of common salt, and one pound of arsenic.

GLASS, common bottle, or green, is formed of sand of any kind, fluxed by the ashes of burnt wood, or of any parts of vegetables; to which may be added the *ferrie* or cinders of forges. When the softest sand is used, two

hundred pounds of wood ashes will suffice for a hundred pounds of sand, which are to be ground and mixed together. The composition with the cinders consists of a hundred and seventy pounds of wood ashes, a hundred pounds of sand, and fifty pounds of cinders, or *ferrie*, which are to be ground and mixed together. If the cinders cannot be ground, they must be broke into small pieces, and mixed with the other matter without any grinding.

Working of PLATE, or LOOKING-GLASS. The materials wherewith *looking-glass* is made, are much the same as those of other works of glass, viz. an alkali salt, and sand.

The salt, however, it is to be observed, should not be that extracted from ploverine, or the ashes of the Syrian kali; but that from barilla, or the ashes of a plant of that name of the genus of kalis, but growing about Alicante in Spain. It is very rare that we can have the barilla pure; the Spaniards, in burning the herb, make a practice of mixing another herb along with it, which alters its quality; or of adding sand to it, to increase the weight, which is easily discovered, if the addition be only made after the boiling of the ashes, but next to impossible if made in the boiling. It is from this adulteration that those threads and other defects in *plate-glass* arise. To prepare the salt, they clean it well of all foreign matters; pound or grind it with a kind of mill, and finally sift it pretty fine.

Pearl-ashes, properly purified, will furnish the alkali salt requisite for this purpose; but it will be necessary to add borax, or common salt, in order to facilitate the fusion, and prevent the glass from thickening in that degree of heat, in which it is to be wrought into plates. For purifying the pearl-ashes, dissolve them in four times their weight of boiling water, in a pot of cast iron, always kept clean from rust. Let the solution be removed into a clean tub, and remain there twenty-four hours, or longer. Having decanted the clear part of the fluid from the dregs or sediment, put it again in the iron pot, and evaporate the water till the salts are left perfectly dry. Preserve them in stone jars, well secured from air and moisture.

Pearl-ashes may also be purified in the highest degree, so as to be proper for the manufacture of the most transparent glass, by pulverizing three pounds of the best pearl-ashes, with six ounces of salt petre, in a glass or marble mortar, till they are well mixed; and then putting part of the mixture into a large crucible, and exposing it in a furnace to a strong heat. When this is red-hot, throw in the rest gradually; and when the whole is red-hot, pour it out on a moistened stone or marble, and put it into an earthen or clean iron pot, with ten pints of water; heat it over the fire, till the salts be entirely melted; let it then stand to cool, and filter it through paper in a pewter cullender. When it is filtered, put the fluid again into the pot, and evaporate the salt to dryness, which will then be as white as snow; the nitre having burnt all the phlogistic matter that remained in the pearl-ashes, after their former calcination.

As to the sand, it is to be sifted and washed, till such time as the water come off very clear; and when it is well dried again, they mix it with the salt, passing the mixture through another sieve. This done, they lay them in the annealing furnace for about two hours; in which time the matter becomes very light and white; in this state they are called *frut*, or *frutas*; and are to be laid up in a dry clean place, to give them time to incorporate: they lie here for at least a year.

When they would employ this *frut*, they lay it for some hours in the furnace, adding to some the fragments or shards of old and ill made glasses, taking care first to calcine the shards by heating them red-hot in the furnace, and thus casting them into cold water. To the mixture must likewise be added magnesia, to promote the fusion and purification.

The best composition for *looking-glass* plate consists of sixty pounds of white sand cleaned, twenty-five pounds of purified pearl-ashes, fifteen pounds of salt-petre, and seven pounds of borax. If a yellow tinge should affect the glass, a small proportion of magnesia, mixed with an equal quantity of arsenic, should be added. An ounce of the magnesia may be first tried; and if this proves insufficient, the quantity should be increased.

A cheaper composition for *looking-glass* plate consists of sixty pounds of the white sand, twenty pounds of pearl ashes, ten pounds of common salt, seven pounds of nitre, two pounds of arsenic, and one pound of borax. The matter of which the glasses are made at the famous manufacture of St. Gobin, in France, is a composition of flint, and of a very white sand; which are carefully cleaned of all heterogeneous bodies; afterwards washed for several times, and dried so as to be pulverized in

mill, consisting of many pebbles, which are moved by horses. When this is done, the sand is sifted through silk sieves, and dried.

The matter, thus far prepared, is equally fit for *plate-glass*, to be formed either for blowing or by casting.

The largest *glasse* at St. Gobin are run; the middle-sized and small ones are blown.

Blowing Lasking-GLASS plates. The workhouses, furnaces, &c. used in the making of this kind of *plate-glass*, are the same, except that they are smaller, and that the carquoises, are disposed in a large covered gallery, over against the furnace, as those in the following article, to which the reader is referred.

After the materials are vitrified by the heat of the fire, and the *glass* is sufficiently refined, the workman dips in his blowing iron, six feet long, and two inches in diameter, sharpened at the end, which is put in the mouth, and widened at the other, that the matter may adhere to it. By this means he takes up a small ball of matter, which sticks to the end of the tube by constantly turning it. He then blows into the tube, that the air may swell the annexed ball; and carrying it over a bucket of water, which is placed on a support at the height of about four feet, he sprinkles the end of the tube to which the matter adheres, with water, still turning it, that, by this cooling, the matter may coalesce with the tube, and be fit for sustaining a greater weight. He dips the tube again into the same pot, and proceeds as before; and, dipping it in the pot a third time, he takes it out, loaded with matter, in the shape of a pear, about ten inches in diameter, and a foot long, and cools it at the bucket; at the same time blowing into the tube, and, with the assistance of a labourer, giving it a balancing motion, he causes the matter to lengthen; which, by repeating this operation several times, assumes the form of a cylinder, terminating like a ball at the bottom, and in a point at the top. The assistant is then placed on a stool three feet and a half high; and on this stool there are two upright pieces of timber, with a cross beam of the same, for supporting the glass and tube, which are kept in an oblique position by the assistant, that the master workman may with a pouchion set in a wooden handle, and with a mallet, make a hole in the mass: this hole is drilled at the centre of the ball that terminates the cylinder, and is about an inch in diameter. When the *glass* is pierced, the defects of it are perceived; if it is tolerably perfect, the workman lays the tube horizontally on a little iron trestle, placed on the support of the aperture of the furnace. Having exposed it to the heat for about half a quarter of an hour, he takes it away, and with a pair of long and broad shears, extremely sharp at the end, widens the *glass*, by insinuating the shears into the hole made with the pouchion, whilst the assistant, mounted on the stool, turns it round, till, at last, the opening is so large as to make a perfect cylinder at bottom. When this is done, the workman lays his *glass* upon the trestle, at the mouth of the furnace, to heat it: he then gives it to his assistant on the stool, and with large shears cuts the mass of matter up to half its height. There is at the mouth of the furnace an iron tool, called *pontil*, which is now heated, that it may unite and coalesce with the *glass* just cut, and perform the office which the tube did before it was separated from the *glass*. This *pontil* is a piece of iron, six feet long, and in the form of a cane or tube, having at the end of it a small iron bar, a foot long, laid equally upon the long one, and making with it a T. This little bar is full of the matter of the *glass*, about four inches thick. This red-hot *pontil* is presented to the diameter of the *glass*, which coalesces immediately with the matter round the *pontil*, so as to support the *glass* for the following operation. When this is done, they separate the tube from the *glass*, by striking a few blows with a chisel upon the end of the tube, which has been cooled; so that the *glass* breaks directly, and makes this separation, the tube being discharged of the *glass* now adhering to the *pontil*. They next present to the furnace the *pontil* of the *glass*, laying it on the trestle to heat, and render the end of that *glass*, that the workman may open it with his shears, as he has already opened one end of it, to complete the cylinder; the assistant holding it on his stool as before. For the last time, they put the *pontil* on the trestle, that the *glass* may become red-hot, and the workman cuts it quite open with his shears, right over-against the forementioned cut; this he does as before, taking care that both cuts are in the same line. In the mean time, the man who looks after the carquoises, comes to receive the *glass* upon an iron shovel, two feet and a half long without the handle, and two feet wide, with a small border of an inch and a half to the right and left, and towards the handle of the shovel. Upon this the *glass* is laid, flattening it a little with a small flick a foot and a half long, so that the cut of the *glass*

is turned upwards. They separate the *glass* from the *pontil*, by striking a few gentle blows between the two with a chisel. The *glass* is then removed to the mouth of the hot carquoise, where it becomes red-hot gradually: the workman, with an iron tool, six feet long, and widened at the end in form of a club at cards, four inches long, and two inches wide on each side, very flat, and not half an inch thick, gradually lifts up the cut part of the *glass*, to unfold it out of its form of a flattened cylinder, and render it smooth, by turning it down upon the breast of the carquoise. The tool, already mentioned, being insinuated within the cylinder, performs this operation, by being pushed hard against all the parts of the *glass*. When the *glass* is thus made quite smooth, it is pushed to the bottom of the carquoise, or annealing furnace, with a small iron raker, and ranged there with a little iron hook. When the carquoise is full, it is stopped and covered as in the case of run *glasse*, and the *glass* remains there for a fortnight to be annealed; after which time, they are taken out to be polished. A workman can make but one *glass* in an hour, and he works and rests for six hours alternately.

It may be observed, that *lasking-glasses*, thus blown, should never be above forty-five, or at most fifty inches long, and of a breadth proportionable. Those exceeding these dimensions, as we frequently find among the Venice *glasse*, cannot have the thickness sufficient to bear the grinding; and besides are subject to warp, which prevents them from regularly reflecting objects.

Casting or running large Lasking-GLASS plates. This art is of French invention, and not quite one hundred years old. It is owing to the Sieur Abraham Thevart, who first proposed it to the court of France, in 1688.

It is performed much like the casting of sheet lead among the plumbers; and by means hereof we are not only enabled to make *glasse* of more than double the dimensions of any made by the Venetian way of blowing; but also to cast all kinds of borders, mouldings, &c.

The furnaces for melting the materials of this manufacture are of enormous size; and those for annealing the *glasse*, when formed, are much more so. Round a melting-furnace, there are at least twenty-four annealing furnaces or ovens; each from twenty to twenty-five feet long; they are called carquoises: each carquoise has two tilfarts, or apertures, to put in wood, and two chimneys. Add, that beside the annealing furnaces, &c. there are others for making of frit, and calcining old pieces of *glass*.

All these furnaces are covered over with a large shed; under which are likewise forges, and workhouses for smiths, carpenters, &c. continually employed in repairing and keeping up the machines, furnaces, &c. as also lodges, and apartments for these, and the other workmen, employed about the *glass*, and keeping up a perpetual fire in the great furnace; so that the *glass-house*, as that in the castle of St. Gobin, in the forest of Fere, in the Solifonnois, appears more like a little city, than a manufactory.

The inside of furnaces is formed of a sort of baked earth proper to sustain the action of fire; and the same earth serves also for melting-pots, cisterns, &c. The furnaces seldom last above three years; after which they are to be rebuilt, from bottom to top; and to keep them good, even for that time, the inside must be refitted every six months, at which time the fire is extinguished. The melting-pots are as big as wine hogheads, about three feet in height, and in diameter; and contain above two thousand weight of metal. The cisterns, or pans, are much smaller, being about thirty-six inches long, eighteen inches wide, and as many deep: and serve for the conveyance of liquid *glass*, which is drawn out of the pots, to the casting tables.

When the furnace is in condition to receive the pots and cisterns, they heat it red-hot, which requires fifty cords, or a hundred cart-loads of wood: this done, they fill the pots with the materials, or folder and sand, which is done at several times, to facilitate the fusion. When the matter is sufficiently vitrified, refined, and settled, which usually happens in thirty-six hours, they fill the cisterns, which are in the same furnace, and which are left there about six hours longer, till such time as they appear all white, through the excessive heat.

To get the cisterns with the metal out of the furnace, they make use of a large iron chain, which opens and shuts with hooks and eyes. From the middle hereof, on each side, arise two massive iron pins, whereby, with the assistance of pulleys, the cisterns are raised upon a kind of carriage of a proper height; and thus conducted to the table where the *glass* is to be run. The cistern is then raised above the tables with an engine, in form of a crane, by means of two iron bars, so contrived as to throw the cistern into an inclined position, which dis-

charges a torrent of matter, all on fire, wherewith the table, prepared for that purpose, is presently covered. The table, whereon the *glais* is to be run, is of cast iron, about ten feet long, and five feet broad. It is supported on a wooden frame, with truckles, for the convenience of removing from one carquassil, or annealing furnace, to another, in proportion as they are filled.

To form the thickness of a *glais*, there are two iron rulers or rims, placed round the edge of the table; and on these rest the two extremities of a kind of roller, of cast iron, which serves to drive the liquid matter before it to the end of the table, or mould. The iron rulers, being moveable, and capable of being set closer, or farther apart, at pleasure, determine the width of the *glais*, and retain the matter, that it does not run off at the edges.

As soon as the matter is arrived at the end of the table, and the *glais* is come to a confluence, examined by the directors of the manufacture, and approved, they shove it off into the annealing furnace, with an iron raker, as wide as the table, that has a handle two fathoms long; being assisted by workmen on the other side of the carquassil, who, with iron hooks, pull the *glais* to them, and range it in the carquassil, which holds six large *glais*.

What is most surprising throughout the whole of this operation, is, the quickness and address, wherewith such maffy cisterns, filled with a flaming matter, are taken out of the furnace, conveyed to the table, and poured therein, the *glais* spreads, &c. The whole is inconceivable to such as have not been eye-witnesses of that surprising manufacture.

As fast as the cisterns are emptied, they carry them back to the furnace and take fresh ones, which they empty as before. This they continue to do, so long as there are any full cisterns; laying as many plates in each carquassil as it will hold, and stopping them up with doors of baked earth, and every chink with cement, as soon as they are full, to let them anneal, and cool again, which requires about fourteen days.

The first running being dispatched, they prepare another, by filling the cisterns anew, from the matter in the pots; and after the second, a third; and even a fourth time, till the melting-pots are quite empty.

The cisterns at each running should remain at least six hours in the furnace to whiten; and when the first annealing furnace is full, the casting-table is to be carried to another. It need not here be observed, that the carquassils, or annealing furnaces, must first have been heated to the degree proper for them. It may be observed, that the oven-full, or the quantity of matter commonly prepared, supplies the running of eighteen *glais*, which is performed in eighteen hours, being an hour for each *glais*. The workmen work six hours, and are then relieved by others.

When the pots are emptied, they take them out, as well as the cisterns, to scrape off what *glais* remains, which otherwise would grow green by continuance of fire, and spoil the *glais*. They are not filled again in less than thirty-six hours, so that they put the matter into the furnace, and begin to run it every fifty-four hours.

The manner of heating the large furnaces is singular enough; the two officers, or persons employed for that purpose, in their shirts, run round the furnace without making the least stop, with a speed scarce inferior to that of the lightest courier; as they go along, they take two billets, or pieces of wood, which are cut for the purpose, these they throw into the first stillart; and continuing their course, do the same for the second. This they hold without interruption for six hours successively; after which they are relieved by others, &c. It is surprising that two such small pieces of wood, and which are consumed in an instant, should keep the furnace to the proper degree of heat; which is such, that a large bar of iron, laid at one of the mouths of the furnace, becomes red-hot in less than half a minute.

It is computed, that a furnace, before it be fit to run *glais*, costs above three thousand five hundred pounds; that at least six months are required for the building it anew, and three months for the refitting it; and that when a pot of matter bursts in the furnace, the loss of matter and time amounts to above two hundred and fifty pounds.

The *glais*, when taken out of the melting-furnace, needs nothing farther but to be ground, polished, and foliated. There is an inland duty of 9s. 4d. a hundred weight on all materials, &c. for making of crown, plate, and flint *glais*, and all white *glais*; and of 2s. 4d. a hundred weight on all materials for making common bottles, and other green *glais*. Upon all crown, plate, and flint *glais* imported, there is a duty of 3d. per pound weight; and on all green, or other *glais* imported, 2d. per pound weight; and on all quart bottles and flasks imported, 2s.

per dozen; and on all bottles and flasks imported, containing more or less than a quart, 2s. per dozen quarts. And if any of the above be landed before entry and payment of duties, they shall be forfeited; and no person is allowed to import into Ireland any of these, that are not of the manufacture of Great Britain, under the penalty of forfeiting the same and ship, and 10s. a pound. *Glais* exported is entitled to a drawback of the duty, 19 Geo. II. cap. 12.

GLASS, annealing of. The operation of annealing of *glais* is performed in a peculiar furnace called the *ler*, which consists of two parts, the *trour* and the *ler*. The vessels as soon as made are placed by the servitors on the floor of the former, to anneal: which done, they are drawn slowly in a sort of pan, called *fraches*, by an operator called the *farle-man*, all along the *ler*, the space of five or six yards, to give them time to cool gradually; so that when they reach the mouth of the *ler*, they are found quite cold. Merret, Not. to Neri, p. 243, seq.

The particles of *glais* by annealing are supposed to lose part of their springiness, and their brittleness at the same time. A gradual heating or cooling of *glais*, according to Dr. Hook, anneals or reduces its parts to a texture more loose, and easy to be broke; but withal more flexible than before. And hence in some measure the phenomena of *glais*-drops.

Borrichius, in his Chemistry, seems to think that the rendering *glais* ductile or malleable, is not so impracticable as it is usually thought; in support of this, he alleges the influence of the *luna cernea*, which is a sort of salt made of silver dissolved in an acid, and which is in some degree ductile, and so far altered from the nature of silver, that it may be melted at a candle, and reduced into small transparent leaves, and adding to this the process for making a ductile salt out of common sal ammoniac, dissolved in a large *glais*, and crystallized a vast many times, the crystals of this salt, he says, at last become half a foot long, and were flexible and elastic, and in some degree ductile under a hammer. From these changes in bodies naturally brittle as salts are, he judges that the same changes may be made in *glais*. Phil. Trans. N° 39.

Glais unannealed are so excessively brittle, as to fly and break of themselves, even frequently before they are well cold. Hence the practice of sealing or annealing was devised.

Some of the phenomena depending on the fragility of unannealed *glais* deserve the attention of the curious. Those of the lacrymæ, or *glais*-drops, were among the first taken notice of; and it has also been observed, that hollow bells made of unannealed *glais*, with a small hole in them, will fly to pieces, by the heat of the hand only, if the hole by which the internal and external air communicate, be stopped with a finger. Phil. Trans. N° 477, p. 3. See ROBERT'S Drops.

But lately some vessels made of such unannealed *glais* have been discovered, which have the remarkable property of resisting very hard strokes given from without, though they fly to pieces by the shocks received from the fall of very light and minute bodies dropped into their cavities. These *glais* may be made of any shape; all that needs be observed in making them, is to take care that their bottoms may be thicker than their sides. The thicker the bottom is, the easier do the *glais* break. One whose bottom is three fingers breadth in thickness, flies with as much ease as lead as the thinnest *glais*. Some of these vessels have been tried with strokes of a mallet, sufficient to drive a nail into wood tolerably hard, and have held good without breaking. They also resist the shock of several heavy bodies let fall into their cavities, from the height of two or three feet. For instance, musket-balls, pieces of iron, or other metal pyrites, Jasper, wood, bone, &c. but this is not surprising, as other *glais* of the same size do the same. But the wonder is, that taking a shiver of flint of the size of a small pea, and letting it fall into the *glais* only from the height of three inches, in about two seconds the *glais* flies, and sometimes in the very moment of the shock: nay, a bit of flint no larger than a grain, dropped into several *glais* successively; though it did not immediately break them, yet they all flew, being set by, in less than three quarters of an hour. Phil. Trans. ibid. p. 509.

Some other bodies produce a like effect with flint: for instance, sapphires, porcelain, diamonds, hard tempered steel, as also marbles, such as boys play with; to which add pearls from the animal kingdom.

The experiments succeeded also when the *glais* were held in the hand, rested on a pillow, put in water, or filled with water. It is also remarkable, that the *glais* broke, upon their bottoms being slightly rubbed with the finger, though some of them did not fly till half an hour after the rubbing.

If the *glafis* be every where extremely thin, they do not break in these circumstances.

Some have pretended to account for these phenomena, by saying, that the bodies dropped into these vessels cause a concussion, that is stronger than the cohesion of the parts of the *glafis*, and that consequently a rupture of the same must ensue. But why does not a ball of gold, silver, iron, copper, or several other bodies, even a thousand times heavier than a shiver of flint, equally cause this concussion, and break the *glafis*?

Mr. Euler has endeavoured to account for these appearances from his principles of percussion. He thinks this experiment entirely overthrows the opinion of those who measure the FORCE of percussion by the *oscilla*; and he thinks the principles he has established give a clear solution of this phenomenon. According to these principles, the extreme hardness of the flint, and also its angular figure, which makes the space of contact with the *glafis* extremely small, ought to cause an impression on the *glafis* vastly greater than lead or any other metal; and this may account for the flint's breaking the vessel, though the bullet, even falling from a considerable height, does no damage. *Mem. Acad. Berlin. 1745. p. 47.*

Hollow cups made of the green *jute-glass*, some of them three inches thick at bottom, were instantly broken, by a shiver of flint weighing about two grains, though they had resisted the shock of a musket ball from the height of three feet. *Phil. Trans. ind. p. 175.*

GLASS of Antimony, in Chemistry. See *Glass of ANTIMONY*, and *VITRUM antimoniacum*.

GLASS, *exempta* of. See *AXUNGIA* and *SANDIVER*.

GLASS of brass. See *BRASS*.

GLASS, *coloured* of. That the colours given to *glafis* may have their full beauty, it must be observed, that every pot when new, and first used, leaves a foulness in the *glafis* from its own earthy parts; so that a coloured *glafis* made in a new pot can never be bright, or perfectly fine. For this reason, the larger of these, when new, may be glazed with white *glafis*; but the second time of using, the pots lose this foulness.

The glazing may be done by reducing the *glafis* to powder, and molting the inside of the pot with water; while it is yet moist, put in some of the powdered *glafis*, and shake it about, till the whole inner surface of the pot be covered by as much as will adhere to it, in consequence of the moisture. Throw out the redundant part of the powdered *glafis*; and the pot being dry, set it in a furnace sufficiently hot to vitrify the *glafis* adhering to it, and let it continue there some time; after which, care must be taken to let it cool gradually.

These pots which have served for one colour must not be used for another; for the remainder of the old matter will spoil the colour of the new. The colours must be very carefully calcined to a proper degree; for if they are calcined either too much or too little, they never do well; the proper proportion, as to quantity, must also carefully be regulated, and the furnaces must be fed with dry, hard wood. And all the processes succeed much the better if the colour be used dividedly, that is, a part of it is the frit, and the rest in the melted metal.

A hard *glafis*, proper for receiving colours, may be prepared by pulverizing twelve pounds of the best sand, cleaned by washing in a *glafis* or flint mortar, and mixing seven pounds of pearl ashes, or any fixed alkaline salt, purified with nitre (see *Pure or Laking-GLASS*, above), one pound of salt-petre, and half a pound of borax, and pounding them together. A *glafis* less hard may be prepared of twelve pounds of white sand cleaned, seven pounds of pearl-salt, purified with salt-petre, one pound of nitre, half a pound of borax, and four ounces of arsenic, prepared as before.

GLASS, *antimony coloured*. See *Purple GLASS*, and *AMETYST*.

GLASS, *balis-coloured*, is made thus: put into a pot crystal frit, thrice washed in water; tinge this with manganese, prepared into a clear purple; to this add *alumen calcinum*, sifted fine, in small quantities, and at several times; this will make the *glafis* grow yellowish, and a little reddish, but not blackish, and always dissipates the manganese. The last time you add manganese, give no more of the *alumen calcinum*, unless the colour be too full. Thus will the *glafis* be exactly of the colour of the *balis-ruby*. See *Ruby GLASS*.

GLASS, to give the common black colour to, the *glafsmakers* use the following method: they take old broken *glafis* of different colours, grind it to powder, and add to it, by different parcels, a sufficient quantity of a mixture of two parts zaffer, and one part manganese: when well purified, they work it into vessels, &c.

GLASS READER are coloured with manganese only. See *Black ENAMEL*.

To give *GLASS* the colour of black velvet. The manner of

giving this deep and fine colour to *glafis*, is this: take of crystalline and pulverine frit, of each twenty pounds; of calc of lead and tin four pounds; let all together in a pot in the furnace, well heated, when the *glafis* is formed and pure, take steel well calcined and powdered, beaten of iron that fly off from the smith's anvil, of each an equal quantity; powder and mix them well together; put six ounces of this powder to the above quantity of metal while in fusion; mix the whole thoroughly together, and let all boil strongly together; then let it stand in fusion twelve hours to purify, and after this work it, in a furnace a most excellent velvet black.

There is another way of doing this, which also produces a very fair black. It is this: take a hundred pounds of rochetta frit, add to this two pounds of tartary, and ten pounds of manganese, both in fine powder; mix them well, and put them to the metal while in fusion, at different times, in several parcels; let it stand in fusion after this for four days, and then work it. *Neri.*

A *glafis* perfectly black may also be formed of ten pounds of either of the compositions for hard *glafis*, above described, one ounce of zaffer, six drams of manganese, and an equal quantity of iron strongly calcined.

GLASS, blue, of a full colour, may be made by adding six drams of zaffer, and two drams of manganese, to ten pounds of either of the compositions for hard *glafis*, described above under *Colours of GLASS*. For a very cool or pale blue *glafis*, half an ounce of calcined copper may be used instead of the manganese, and the proportion of zaffer diminished by one half. *Glafis* resembling *sapphire* may be made with ten pounds of either of the compositions for hard *glafis* three drams, and one scruple of zaffer, and one dram of the calc of iron, or precipitation of gold by tin; or instead of this latter ingredient, two drams and two scruples of manganese. Or, a sapphire-coloured *glafis* may be made by mixing with any quantity of the hard *glafis* one eighth of its weight of iron.

GLASS, to give Venetian, with gold spangles, commonly called the *philosopher's stone*, may be prepared in the following manner: take of the second composition for hard *glafis* above described, and of the composition for *PASTE*, of each five pounds, and of highly calcined iron an ounce; mix them well, and fuse them till the iron be perfectly vitrified, and has tinged the *glafis* of a deep transparent, yellow brown colour. Powder this *glafis*, and add to it two pounds of powdered *glafis* of antimony; grind them together, and thus mix them well. Take part of this mixture, and rub into it fourscore or one hundred leaves of the counterfeit leaf gold, called Dutch gold; and, when the parts of the gold seem sufficiently divided, mix the powder containing it with the other part of the *glafis*. Fuse the whole with a moderate heat, till the powder run into a vitreous mass, fit to be wrought into any of the figures or vessels into which it is usually for *golds*; but avoid a perfect liquefaction; because that, in a short time, destroys the equal diffusion of the spangles, and vitrifies, at least in part, the matter of which they are composed; converting the whole into a kind of transparent, olive-coloured *glafis*. This kind of *glafis* is used for a great variety of toys and ornaments with us, who, at present, procure it from the Venetians. *Handbook to the ART, vol. II. p. 317.* See *Gold-coloured GLASS*.

GLASS, *chalcidary*. A mixture of several ingredients, with the common matter of *glafis*, will make it represent the semi-opaque gems, the jaspers, agates, chalcidones, &c. The way of making these seems to be the same thing with the method of making marbled paper, by several colours dissolved in several liquors, which are such as will not readily mix with one another when put into water, before they are call upon the paper which is to be coloured. There are several ways of making these variously coloured *glafes*, but the best is this: dissolve four ounces of fine leaf silver in a *glafis* vessel in strong aqua fortis; stop up the vessel, and let it abide.

In another vessel, dissolve five ounces of quicksilver in a pound of aqua fortis, and let it abide.

In another *glafis* vessel, dissolve in a pound of aqua fortis three ounces of fine silver, first calcined in this manner: mix the silver with mercury, mix the amalgam with twice its weight of common salt well purified, put the mixture in an open fire in a crucible, that the mercury may fly off, and the silver be left in form of powder. Mix this powder with an equal quantity of common salt well purified, and calcine this for six hours in a strong fire; when cold, wash off the salt by repeated boiling in common water, and then put the silver into the aqua fortis. Set this solution also aside.

In another vessel, dissolve in a pound of aqua fortis three ounces of sal ammoniac; pour off the solution, and dissolve in it a quarter of an ounce of gold. Set this aside.

In another vessel, dissolve three ounces of sal ammoniac in a pound of aqua fortis; then put into the solution cinabar, crocus martis, ultramarine, and ferretto of Spain, of each half an ounce. Set this also aside.

In another vessel, dissolve in a pound of aqua fortis three ounces of sal ammoniac; then put into it crocus martis, made with vinegar, calcined tin, zaffer, and cinabar, of each half an ounce; let each of these be powdered very fine, and put gently into the aqua fortis. Set this also aside.

In another vessel, dissolve three ounces of salammoniac in a pound of aqua fortis, and add to it brals calcined with brimstone, brals thicke calcined, manganese, and scales of iron which fall from the smith's anvil, of each half an ounce; let each be well powdered, and put gently into the vessel. Then let this also aside.

In another vessel, dissolve two ounces of sal ammoniac in a pound of aqua fortis, and put to it verdigrise an ounce, red lead, crude antimony, and the caput mortuum of vitriol, of each half an ounce; put these well powdered leisurely into the vessel, and let this also aside.

In another vessel, dissolve two ounces of sal ammoniac in a pound of aqua fortis, and add orpiment, white arsenic, painters lake, of each half an ounce; keep these nine vessels in a moderate heat for fifteen days, shaking them well at times. After this pour all the matters from these vessels into one large vessel, well luted at its bottom; let this stand six days, shaking it at times, and then let it in a very gentle heat, and evaporate all the liquor, and there will remain a powder of a purplish green.

When this is to be wrought, put into a pot very clear metal, made of broken crystalline and white glass, that has been used; for with the virgin-rit, or such as has never been wrought, the chalcidone can never be made, as the colours do not stick to it, but are consumed by the rit. To every pot of twenty pounds of this metal, put two or three ounces of this powder at three several times; incorporate the powder well with the glass, and let it remain an hour between each time of putting in the powder. After all are in, let it stand twenty-four hours; then let the glass be well mixed, and take an assay of it, which will be found of a yellowish blue; return this many times into the furnace, when it begins to grow cold, it will show many waves of different colours very beautifully. Then take tartar eight ounces, foot of the chimney two ounces, crocus martis made with brimstone, half an ounce; let these be well powdered and mixed, and put them, by degrees, into the glass at six times, waiting a little while between each putting in; when the whole is put in, let the glass boil and settle for twenty-four hours; then make a little glass body of it, which put in the furnace many times, and see if the glass be enough, and whether it have on the outside veins of blue, green, red, yellow, and other colours; and have before these veins, waves, like those of the chalcidone, jaspers, and oriental agates, and if the body kept within looks as red as fire.

When it is found to answer thus it is perfect, and may be worked into toys and vessels, which will always be beautifully variegated; these must be well annealed, which adds much to the beauty of their veins. Masses of this may be polished at the lapidary's wheel as natural stones, and appear very beautiful. If in the working the matter grow transparent, the work must be stopped, and more tartar, foot, and crocus martis, must be put to it, which will give it again the necessary body and opacity, without which it does not show the colours well. *Neri.*

GLASS resembling the CHRYCOLITE may be made of ten pounds of either of the compositions for hard glass, described above, and six drams of calcined iron.

GLASS resembling the RED CORNELIAN may be formed by adding one pound of glass of antimony, two ounces of the calcined vitriol, called *flushe okers*, and one dram of manganese, or magnesia, to two pounds of either of the compositions for hard glass. The glass of antimony and magnesia are first fused with the other glass, and then powdered and ground with the flushe oker; the whole mixture is afterwards fused with a gentle heat, till all the ingredients are incorporated. A glass resembling the white cornelian may be made of two pounds of either of the compositions for hard glass, and two drams of yellow oker, well washed, and one ounce of calcined bones. Grind them together, and fuse them with a gentle heat.

GLASS, emerald. See *Green GLASS*.

GLASS, garnet-coloured. To give this colour to glass, the workmen take the following method. They take equal quantities of crystal and rochetta frit, and to every hundred weight of this mixture, they add a pound of manganese, and an ounce of prepared zaffer: these are to be powdered separately, then mixed and added by degrees to the frit while in the furnace: great care is to be taken to mix the manganese and zaffer very perfectly; and

when the matter has stood twenty-four hours in fusion, it may be worked. *Neri.*

GLASS of this kind may be made by adding one pound of glass of antimony, one dram of manganese, and the same quantity of the precipitate of gold by tin, to two pounds of either of the compositions for hard glass, or the precipitate of gold may be omitted, if the quantities of the glass of antimony and manganese be doubled.

GLASS, gold-coloured. This kind of glass may be made by taking ten pounds of either of the compositions for hard glass, omitting the salt-petre; and for every pound adding an ounce of calcined borax, or, if this quantity doth not render the glass sufficiently fusible, two ounces; ten ounces of red tartar, of the deepest colour, two ounces of magnetis, and two drams of charcoal of fallow, or any other soft kind. Precipitate of silver baked on glass will stain it yellow, and likewise give a yellow colour on being mixed with, and melted with forty or fifty times their weight of vitreous compositions; the precipitate from aqua fortis, by fixed alkali, seems to answer best. Yellow glasses may also be obtained with certain preparations of iron, particularly with *Prussias aures*. But *Dr. Lewis* observes, that the colour does not constantly succeed, nor approach to the high yellow of gold, with silver or with iron. The nearest imitations of gold which he has been able to produce, have been affected with antimony and lead. Equal parts of the glass of antimony, of flint calcined and powdered, and of minium, formed a glass of a high yellow; and with two parts of glass of antimony, two of minium, and three of powdered flint, the colour approached still more to that of gold. The last composition exhibited a multitude of small sparkles interspersed through its whole substance, which gave it a beautiful appearance in the mass, but were really imperfections, owing to air-bubbles.

Neri directs, for a gold-colour, one part of red tartar, and the same quantity of manganese, to be mixed with a hundred parts of frit. But *Kunckel* observes, that these proportions are faulty; that one part, or one and a quarter of manganese, is sufficient for a hundred of frit; but that six parts of tartar are hardly enough, unless the tartar is of a dark red colour, almost black; and that he found it expedient to add to the tartar about a fourth of its weight of powdered charcoal. He adds that the glass swells up very much in melting, and that it must be left untirred and worked as it stands in fusion. *Mr. Samuel More*, in repeating and varying this process in order to render the colour more perfectly fixed, found that the manganese is entirely unnecessary to the gold colour, and that the tartar is no otherwise of use, than in virtue of the coaly matter, to which it is in part reduced by the fire; the phlogiston or inflammable part of the coal appearing, in several experiments, to be the direct staining substance. *Mr. Pott* also, in his *Neue Wichtige Physikalisch-Chymische Materien*, &c. printed in 1702, observes, that common coals give a yellow colour to glass; that different coals matters differ in their staining power; that caput mortuum of foot and lump-black answer better than common charcoal; and that the sparkling coal, which remains in the retort after the redification of the thick empyreumatic animal oils, is one of the most active of these preparations. This preparation, he says, powdered, and then burnt again a little in a clove wood, is excellent for tinging glass, and gives yellow, brown, reddish, or blackish colours, according to its quantity; but the frit must not be very hard of fusion; for, in this case, the strong fire will destroy the colouring substance before the glass melts; and he has found the following compositions to be nearly the best; viz. sand two parts, alkali three parts; or sand two, alkali three, calcined borax one; or sand two, alkali two, calcined borax one; and, though salt petre is hardly used at all, or very sparingly, for yellow glass, as it too much volatilizes the colouring substance; yet here for the most part a certain proportion of it, easily determined by trial, is very necessary; for, without it, the concentrated colouring matter is apt to make the glass too dark, and even of an opaque pitchy blackness. It does not certainly appear that there is any material diversity in the effects of different coals; the difference being, probably owing to the different quantities of the inflammable matter, which they contain; so that a little more shall be required of one kind than of another, for producing the same degree of colour in the glass. Nor does the fusibility or solubility of the frit appear to be in any respect necessary.

Gold-coloured spangles may be dissolved through the substance of glass, by mixing the yellow tints with powdered glass, and bringing the mixture into fusion. See *Lewis's Com. Phil. Techn.* p. 626. 223, &c.

GLASS, green, may be made by adding three ounces of copper, precipitated from aqua fortis, and two drams of precipitated iron to nine pounds of either of the compo-

sitions

fusions for hard *glass*. The finest method of giving this beautiful colour to *glass* is this. Take five pounds of crystalline metal, that has been passed several times through water, and the same quantity of the common white metal of polverine, four pounds of conjoin polverine frit, and three pounds of red-lead; mix the red-lead well with the frit, and then put all into a pot in a furnace. In a few hours the whole mass will be well purified; then call the whole into water, and separate, and take out the lead; then return the metal into the pot, and let it stand a day longer in fusion; then put in the powder of the residuum of the vitriol of copper, and a very little crocus martis, there will be produced a most lively and elegant green, scarce inferior to that of the Oriental emerald. There are many ways of giving a green to *glass*, but all are greatly inferior to this. Neri. See EMERALD.

GLASS, sea-green. To make this colour in the *glass-trade*, the finest crystalline *glass* only must be used, and no manganese must be added at first to the metal. The crystal frit must be melted thus alone, and the salt, which swims like oil on its top, must be taken off with an iron ladle very carefully. Then to a pot of twenty pounds of this metal, add six ounces of calcined bris, and a fourth part of the quantity of powdered saffer; this powder must be well mixed, and put into the *glass* at three times, it will make the metal swell at first, and all must be thoroughly mixed in the pot. After it has stood in fusion three hours, take out a little for a proof; if it be too pale, add more of the powder. Twenty-four hours after the mixing of the powder the whole will be ready to work, but must be well stirred together from the bottom, lest the colour should be deeper there, and the metal at the top less coloured, or even quite colourless. Some use for this purpose half crystal frit, and half rochetta frit, but the colour is much the finest, when all crystal frit is used. Neri.

GLASS, for counterfeiting lapis lazuli. See Lapis LAZULI.

GLASS, resembling opal. See OPAL.

GLASS, purple, of a deep and bright colour, may be produced, by adding to ten pounds of either of the compositions for hard *glass*, above described, six drams of saffer, and one dram of gold, precipitated by tin; or to the same quantity of either composition one ounce of manganese, and half an ounce of saffer. The colour of AMETHYST may be imitated in this way. See RUBY GLASS.

GLASS, red. A blood-red *glass* may be made in the following manner; put six pounds of *glass* of lead, and ten pounds of common *glass* into a pot glazed with white *glass*. When the whole is boiled and refined, add by small quantities, and at small distances of time, copper calcined to a redness, as much as on repeated proofs is found sufficient; then add tartar in powder by small quantities at a time, till the *glass* is become as red as blood; and continue adding one or other of the ingredients till the colour is quite perfect. Neri.

GLASS, ruby. The way to give the true fine red of the ruby, with a fair transparency, to *glass*, is as follows. Calcine in earthen vessels gold dissolved in aqua regia, the menstruum being evaporated by distillation, more aqua regia added, and the abstraction repeated five or six times, till it becomes a red powder. This operation will require many days in a hot furnace; when the powder is of a proper colour, take it out; and when it is to be used, melt the finest crystal *glass*, and purify it, by often casting it into water; and then add, by small quantities, enough of this red powder to give it the true colour of a ruby, with an elegant and perfect transparency. Neri.

The process of tinging *glass* and enamels, by preparations of gold, were first attempted about the beginning of the last century. Libanius, in one of his tracts, entitled *Alchymia*, printed in 1606, conjectures, that the colour of the ruby proceeds from gold, and that gold dissolved, and brought to redness, might be made to communicate a like colour to factitious gems and *glass*. On this principle Neri, in his *Art of Glass*, dated 1611, gives the process above recited. Glauber, in 1648, published a method of producing a red colour by gold, in a matter which is of the vitreous kind, though not perfect *glass*. For this purpose he ground powdered flint or sand with four times its weight of fixed alkaline salt; this mixture melts in a moderately strong fire, and when cold looks like *glass*, but, exposed to the air, runs into a liquid state. On adding this liquor to solution of gold in aqua regia, the gold and flint precipitate together in form of a yellow powder, which by calcination becomes purple; by mixing this powder with three or four times its weight of the alkaline solution of flint, drying the mixture, and melting it in a strong fire for an hour, a mass is obtained, of a transparent ruby colour, and of a vitreous appearance, which, nevertheless, is soluble in water, or by

the moisture of the air, on account of the redundancy of the salt. The honourable Mr. Boyle, in a work published in 1680, mentions an experiment, in which a pale colour was introduced into *glass* without fusion; for, having kept a mixture of gold and mercury in digestion for some months, the fire was at last immoderately increased, so that the *glass* burnt with a violent explosion; and the lower part of the *glass* was found tinged throughout with a transparent red colour, hardly to be equalled by that of rubies. See Porosity of Bodies, in Shaw's Abridgement of Boyle's Works, vol. I. p. 459, and Appendix to the Sceptical Chymist.

About the same time Cassius is said to have discovered the precipitation of gold by tin, and that *glass* might be tinged of a ruby colour by melting it with this precipitate: though he does not appear, says Dr. Lewis, from his treatise *De Auro*, to have been the discoverer of either. He describes the preparation of the precipitate, and its use, but gives no account of the manner of employing it, only that he says, one dram of gold, duly prepared, will tinge ten pounds of *glass*. See GOLD precipitate with tin.

This process was soon after brought to perfection by Kunkel; who says, that one part of the precipitate is sufficient to give a ruby colour to 1280 parts of *glass*, and a sensible redness to upwards of 1900 parts; but that the success is by no means constant. Kunkel also mentions a purple-gold powder, resembling that of Neri, which he obtained by insipidifying solution of gold to ten parts, abstracting from it fresh aqua regia three or four times, till the matter appears like oil; then precipitating with strong alkaline ley, and washing the precipitate with water. By dissolving this powder in spirit of salt, and precipitating again, it becomes, he says, extremely fair; and in this state he directs it to be mixed with a due proportion of Venice *glass*.

Orichal, in a treatise entitled *Sol sine Velle*, gives the following process for producing a very fine ruby. He directs the purple precipitate, made by tin, to be ground with six times its quantity of Venice *glass* into a very fine powder, and this compound to be very carefully mingled with the frit or vitreous composition to be tinged. His frit consists of equal parts of borax, nitre, and fixed alkaline salt, and four times as much calcined flint as of each of the salts; but he gives no directions as to the proportion of the gold precipitate, or mode of fusion. Heliot describes a preparation, which, mixed with Venice *glass*, was found to give a beautiful purple enamel. This preparation consists of equal parts of solution of gold, and of solution of zinc in aqua regia, mixed together, with the addition of a volatile salt prepared from sal ammoniac, by quicklime, in sufficient quantity to precipitate the two metals. The precipitate is then gradually heated, till it acquires a violet colour. However, though a purple or red colour, approaching to that of ruby, may, by the methods above recited, be baked on *glass* or enamels, and introduced into the mass by fusion, the way of equally diffusing such a colour through a quantity of fluid *glass*, is still, says Dr. Lewis, a secret. The following process for making the ruby *glass* was communicated to Dr. Lewis by an artist, who ascribed it to Kunkel. The gold is directed to be dissolved in a mixture of one part of spirit of salt, and three of aqua fortis, and the tin in one part of the mixture of the former of these acids with two of the latter. The solution of gold being properly diluted with water (see GOLD precipitate, &c.) the solution of tin is added, and the mixture left to stand till the purple matter has settled to the bottom. The colourless liquor is then poured off, and the purple sediment, while moist, and not very thick, is thoroughly mixed with powdered flint or sand. This mixture is well ground with powdered nitre, tartar, borax, and arsenic, and the compound melted with suitable fire. The proportions of the ingredients are 2560 parts of sand, 384 of nitre, 240 of tartar, 240 of borax, 28 of arsenic, 5 of tin, and 5 of gold. Lewis's Chem. Phil. Techn. p. 171. 681, &c.

GLASS, resembling the TOPAZ may be made by pulverising ten pounds of either of the compositions for hard *glass*, with an equal quantity of the gold-coloured *glass* powder, and mixing them together.

GLASS, white opake, and semi-transparent, may be made in ten pounds of either of the compositions for hard *glass*, and one pound of well calcined horn, ivory, or bone; or an opake whiteness may be given to *glass*, by adding one pound of very white arsenic to ten pounds of *glass*. Let them be well powdered and mixed, by grinding them together; and then fused with moderate heat, till they are thoroughly incorporated. A *glass* of this kind is made in large quantities at a manufactory at London, and used not only for different kinds of vessels, but as a white ground for enamel in dial-plates and sundials.

boxes, which do not require gilding with much fire, because it becomes very white and subtile with a moderate heat.

GLASS, yellow. See *Gold-coloured GLASS*.

GLASS, balls, which are circular or otherwise shaped hollow vessels of glass, may be coloured within, to imitate the semi-transparent gems. The method of doing it is this: make a strong solution of ischycolia, or singlala, in common water, by boiling; pour a quantity of this while warm into the hollow of a white glass vessel; shake it thoroughly about, that all the sides may be wetted, and then pour off the rest of the moisture. Immediately after this, throw in red-lead, shake it and turn it about, throw it into many places with a tube, and the moisture will make it thick and run in waves and penny figures. Then throw in some of the painter's blue salt, and make it run in waves in the ball as the red-lead; then do the same with verdigrise, next with opiment, then with red-lake, all well ground; always adding in the colours in different places, and turning the glass, that the moisture within may run them into the waves. Then take fine plaster of Paris, and put a quantity of it into the balls, shake it also nicely about; this will ever where stick firmly to the glass, and give it a strong inner coat, keeping all the colours on very fairly and strongly. These are set on frames of carved wood, and much esteemed as ornaments in many places. *See* **Nei.**

GLASS, drops. See **ROBERT'S drop.**

GLASS, fading of. See **FOLIATING and LOOKING-GLASS.**

GLASS, gilding of. See **GILDING of enamel and glass.**

GLASS, grinding of. See **GRINDING.**

GLASS of lead, a glass made with the addition of a large quantity of lead, of great use in the art of making counterfeits. The method of making it is this: put a large quantity of lead into a potter's kiln, and keep it in a state of fusion with a moderate fire, till it is calcined to a grey loose powder; then spread it in the kiln, and give it a greater heat, continually stirring it to keep it from running into lumps; continue this several hours, till the powder becomes of a fair yellow; then take it out, and sift it fine: this is called calcined lead.

Take of this calcined lead fifteen pounds, and crystalline, or other frit, twelve pounds; mix these as well as possible together; put them into a pot, and set them in the furnace for ten hours; then call the whole which will be now perfectly melted, into water; separate the loose lead from it, and return the metal into the pot; and after standing in fusion twelve hours more, it will be fit to work. It is very tender and brittle, and must be worked with great care, taking it slowly out of the pot, and continually wearing the marble it is wrought upon. *See* **Nei.** It is well known, that cerule, or white lead, minium, litharge, and all the other preparations and calces of lead, are easily fused by a moderate fire, and formed into a transparent glass of a deep yellow colour. But this glass is so penetrating and powerful a flux, that it is necessary to give it a greater confidentiality, in order to render it fit for use. With this view, two parts of calc of lead, e. g. minium, and one part of sand, or powdered flint, may be put into a crucible of refractory clay, and baked into a compact body. Let this crucible, well closed with a luted lid, be placed in a melting furnace, and gradually heated, for an hour, or an hour and a half; and afterwards let the heat be increased, so as to obtain a complete fusion, and continued in that state for the same time: let the crucible remain to cool in the furnace, and when it is broken, a very transparent yellow-coloured glass will be found in it. Some add nitre and common salt to the above mixture, because these salt promote the fusion and the more equal distribution of the sand. This glass of lead has a considerable specific gravity, and its heaviest part is always the heaviest. It is an important flux in the assays of ores to facilitate their fustifications.

Glass of lead is capable of all the colours of the gems in very great perfection. The methods of giving them are these: for green, take pulverine frit twenty pounds, lead calcined sixteen pounds; sift both the powders very fine, then melt them in a glass, separating the un-mixed lead, by plunging the mass in water; after this return it into the pot, and add back these calcined frit sources, and one penny-weight of crocus martis made with vinegar; put this in at six different times, always carefully mixing it together; let it finally settle an hour, then mix it together, and take a proof of it; when the colour is right, let it stand eight hours, and then work it. If instead of the calcined frit the same quantity of the caput mortuum of the vitriolum veneris be used, the green is yet much finer.

For topaz-colour, take crystal frit fifteen pounds, calcined lead twelve pounds; mix them well together, by sifting the powders through a fine sieve; then set them in a furnace not too hot, and separate the superfluous un-

mixed lead, by casting the whole into water; repeat this twice; then add half gold yellow glass, and let them incorporate and purify, and they will be of the true and exact colour of the oriental topazes.

For sea-green, take crystal frit sixteen pounds, calcined lead ten pounds; mix and sift them together, and set them in a pot in a furnace; in twelve hours the whole will be melted; then call it into water, and separate it from the loose lead; put them into the furnace again for eight hours; then separate the loose lead by washing a second time, and return it to the pot for eight hours more. *See* **Nei.**

GLASS, painting in. The primitive manner of painting in glass was very simple, and of consequence very easy: it consisted in the more arrangement of pieces of glass of different colours, in some sort of symmetry; and constituted a kind of what we call *Mosaic work*.

Afterwards, when they came to attempt more regular designs, and even to represent figures raised with all the shades, their whole address went no farther than to the drawing the contours of the figures in black, with water colours, and hatching the draperies, after the same manner, on glass of the colour of the object intended to be painted. For the carnations, they chose glass of a bright red; upon which they designed the principal lineaments of the face, &c. with black.

At last the taste for this sort of painting being considerably improved, and the art being found applicable to the adorning of churches, basilicas, &c. they found means of incorporating the colours with the glass itself, by exposing them to a proper degree of fire, after the colours had been laid on.

A French painter at Marseilles is said to have given the first notion hereof, upon going to Rome, under the pontificate of Julius II. But Albert Durer, and Lucas of Leyden were the first that carried it to any height.

The colours used in painting on glass are very different from those used either in painting in oil or water.

The *base* is made of two thirds of flakes, or scales of iron, beaten up, and mixed with another third of recalle, or little glass beads. *White*, with sand, or little white pebbles, calcined, pounded in a mortar, and afterwards ground on marble; with one fourth part of salt-petre added thereto, and the mixture calcined and pulverized over again; to which, when they are ready to use it, is added a little gypsum, or plaster of Paris well ground, &c. For *yellow*, they used lead-fire ground, mixed up in a crucible with sulphur, or salt-petre; then well beaten and ground on a porphyry stone; and, at length, ground over again with nine times as much red ochre. *Red* is made of litharge of silver, and scales of iron, gum Arabic, ferretta, glass beads, and blood stone, nearly in equal quantities. This is one of the most difficult colours; and the preparation only to be learned by experience.

Green is made of 25 anulum, one ounce as much black lead, and four ounces of thine sand, incorporated by the fire. After calcination, they add a fourth part of salt-petre; after a second calcination, a sixth part more: after which they make a third calcination before it is used. *Azure, purple, and violet*, are prepared like green, only leaving out the 25 anulum, and in the lieu thereof using sulphur for azure; perigueux, for purple; and both these drugs for violet. *Carnations* are made of ferretta and recalle. And lastly, colours for the hair, trunks of trees, &c. are made of ferretta, recalle, &c.

This account of colours we have from M. Feilbich's excellent work *Des Principes d'Architecture*, &c. though it must be owned, that all the painters on glass do not use them; there being few artists of that kind but have invented their own particular ones, whereof they usually make great secrets. But this is certain, that these above described are sufficient for the best paintings of all sorts; provided the person has but the skill to manage them. In the windows of divers ancient churches, chapels, colleges, &c. we meet with the most beautiful and lively colours imaginable; such as far exceed any used among us: but it is not that the secret of making these colours is lost; but that the moderns would not go to the expense of them; nor take all the necessary pains; because this sort of painting is not now so much esteemed as formerly.

Mr. Walpole, in his *Anecdotes of Painting in England*, has traced the history of this art from the Reformation, when misguided zeal destroyed most of the monuments of it in our churches, through a series of professors to the present time. In Aubrey's manuscript survey of Wilt, in the library of the Royal Society, it is said, on the authority of Sir W. Dugdale, that the first painted glass in England was done in King John's time; and Mr. Walpole produces instances of it in the reign of King Henry III. Among the later proficient in this art were Isaac Oliver, who painted the windows at Christchurch, Oxford in 1700, William Price, who in the same year painted the window in Merton-chapel, *William Price*

Poles the fan, to whose art we owe the windows at Queen's New-college, and Maudlin, of whom Mr. Walpole says, that his colours are fine, his drawing good, and his taste in ornaments and Mosaic far superior to any of his predecessors, and equal even to the antique. In 1761 Mr. Parrish, an auctioneer, late of Essex-house in London, exhibited the two first auctions of painted glass imported from Flanders; and undertook also to establish a manufactory of painted glass: several of the pieces of this ingenious artist exhibited colours vying in perfection with the old paintings.

Those beautiful works, among the painters in glass, which were made in the glass-house, were of two kinds: in some, the colour was diffused through the whole body of glass; in others, which were the more common, the colour was only on one side, faster penetrating within the substance above one third of a line; though this was more, or less, according to the nature of the colour; the yellow being always found to enter the deepest.

These last, though not so strong and beautiful as the former, were of more advantage to the workmen; because, on the same glass, though already coloured, they could draw other kind of colours, where there was occasion to embody draperies, enrich them with foliage, or represent other ornaments of gold, silver, &c.

In order to this, they made use of emery grinding, or wearing down the surface of the glass, till such time as they were got through the colour, to the clear glass: this done, they applied the proper colours on the other side of the glass. By this means the new colours were prevented from running, and mixing among the former, when the glass came to be exposed to the fire, as will hereafter be shown.

When the intended ornaments were to appear white, or silvered, they contented themselves to bare the glass of its colour with emery, without applying any new colour at all; and it was in this manner, that they wrought the lights and heightenings on all kinds of colours.

The painting with vitreous colours on glass depends entirely on the same principles as painting in enamel; and the manner of executing it is likewise the same, except that in this the transparency of the colours being indispensable requisite, no substances can be used to form them but such as vitrify perfectly: and, therefore, the great object is to find a set of colours, which are composed of such substances, as by the admixture of other bodies may promote their vitrification and fusion: are capable of being converted into glass; and melting, in that state, with less heat than is sufficient to melt such other kinds of glass as may be chosen for the ground or body to be painted: to transfer these colours, so as to make them proper to be worked with a pencil, and to burn or reduce them by heat, to a due state of fusion, without injuring or melting the glass which constitutes the body painted. The first thing to be done, in order to paint on glass, in the modern way, is to design, and even colour, the whole subject on paper. Then they make choice of pieces of glass proper to receive the several parts, and proceed to divide or distribute the design itself, or the paper it is drawn on, into pieces suitable to those of glass: having always a view that the glass may join in the contours of the figures, and the folds of the draperies; that the cariations, and other finer parts, may not be damaged by the lead where the pieces are to be joined together.

The distribution being made, they mark all the pieces, as well as papers, with letters, or numbers: that they may be known again, which done, applying each part of the design on the glass intended for it, they copy or transfer the design upon this glass, with the black colour, diluted in gum-water; by tracing and following all the lines and strokes, as they appear through the glass, with the point of a pencil.

When these first strokes are well dried, which happens in about two days, the work being only in black and white, they give it a slight wash over, with urine, gum Arabic, and a little black; and this several times repeated, according as the shades are desired to be heightened; with this precaution, never to apply a new wash, till the former is sufficiently dried. This done, the lights and tinges are given, by rubbing off the colour in the respective places, with a wooden point, or the handle of the pencil.

As to the other colours above mentioned, they are used with gum-water, much as in painting in miniature; taking care to apply them lightly, for fear of effacing the guidelines of the design; or even, for the greater security, to apply them on the other side, especially yellow, which is very pernicious to other colours, by blending therewith.

And here too, as in pieces of black and white, particular regard must be always had, not to lay colour on colour, or lay on a new lay, till such time as the former are well dried. It may be added, that the yellow is the only

colour that penetrates through the glass, and incorporates therewith by the fire: the red, and particularly the blue, which is very difficult to use, remaining on the surface, or at least entering very little. When the painting of all the pieces is finished, they are carried to the furnace, or oven, to anneal or bake the colours. The furnace here used is small, built of brick, from eighteen to thirty inches square: at six inches from the bottom is an aperture, to put in the fuel, and maintain the fire. Over the aperture is a grate, made of three square bars of iron, which traverse the furnace, and divide it into two parts: fifteen inches above this partition is another little aperture, through which they take out pieces, to examine how the colour goes forward.

On the grate is placed a square earthen pan, six or seven inches deep, and five or six inches less, every way, than the perimeter of the furnace. On one side thereof is a little aperture, through which to make the trivets placed directly opposite to that of the furnace destined for the same end.

In this pan are the pieces of glass to be placed in the following manner: first, the bottom of the pan is covered with three strata, or layers of quicklime, pulverised; these strata being separated by two others, of old broken glass: the design whereof is to secure the painted glass from the too intense heat of the fire. This done the glasses are laid horizontally on the last, or uppermost, layer of lime.

The first row of glass they cover over with a layer of the same powder an inch deep, and over this they lay another range of glass; and thus alternately, till the pan is quite full, taking care that the whole heap always ends with a layer of the lime powder.

The pan thus prepared, they cover up the furnace with tiles, on a square table of earthenware, closely jointed all round, only leaving five little apertures, one at each corner and another in the middle, to serve as chimneys.

Things thus disposed, there remains nothing but to give the fire to the work. The fire for the two first hours must be very moderate; and must be increased, in proportion as the cotton advances, for the space of ten or twelve hours; in which time it is usually completed. At last, the fire, which at first was only of charcoal, is to be of dry wood: so that the flame covers the whole pan, and even issues out at the chimneys.

During the last hours, they make assay from time to time, by taking out pieces laid for that purpose, through the little aperture of the furnace, and see, to see whether the yellow be perfect, and the other colours in good order. When the annealing is thought sufficient, they proceed with great haste to extinguish the fire, which otherwise would soon burn the colours, and break the glass.

GLASS, painting on, by means of spirits. See BACK-Painting. GLASS, polishing of. See POLISHING and GRINDING.

GLASS-PORECELAIN, the name given by many to a modern invention of imitating the china-ware with glass. The method given by Mr. Reaumur, who was the first that carried the attempt to any degree of perfection, is delivered by that gentleman in the Memoirs of the Academy of Sciences of Paris to this effect. This change of glass was first taken notice of by Neumann, who, in distilling milk in a glass retort observed, that the bottom of the vessel acquired the appearance of porcelain, which he attributed to the fine white earthy matter of the milk forced into the glass by heat. Neum. Chém. Works by Dr. Lewis, p. 571.

The mixing glass reduced to powder, with other less easily vitrifiable substances for the forming a paste to be afterwards made into a sort of porcelain, has been a contrivance long practised, but it is very troublesome, and the result subject to many faults; but this new way is made of glass alone, and that with much less trouble, and without the recourse to powder. By this art, vessels of glass are changed into vessels of a sort of porcelain, without altering their form, and the manner glass serves as well as the best for that purpose: our common coarse green quart-bottles, or the great bell glasses with which gardeners cover their cabbages, &c. being by this method changeable into a beautiful white sort of porcelain-ware; and this is to be done in so easy a manner, and with so small expence, that it requires no more trouble or charge, than that of baking a common vessel of our coarse earthenware, and for this reason the vessels of this sort of ware may be afforded extremely cheap.

It is very certain, that all porcelain-ware is a substance in the state of semivitrification; and in order to being glass, which is a wholly vitrified substance, into the condition of porcelain, there requires no more than to reduce it to a less perfectly vitrified state.

The question which would naturally be started on this occasion, is, whether it be possible to reduce glass to a less vitrified

vitrified state, it having already undergone what is termed the last change by fire. But when we consider, that the *glaze* of antimony, the vitrification of many of the metals, as the *glaze* of lead, and the commonest gems coloured by the metals, are more or less easily reduced again by chemistry to metals, &c. the reducing of fossils, flints, &c. after they are vitrified, at least a little way back toward their native or prilline state, may appear not wholly impracticable, and the attempts which Mr. Bessemier made on this occasion, were what gave him the full hint of the *glaze*-porcelain.

The method of making it is this. The *glaze*-refracts to be converted into porcelain, are to be put into a large earthen vessel, such as the common fine earthen dishes are baked in, or into sufficiently large crucibles; the vessels are to be filled with a mixture of fine white sand, and of fine gypsum or plaster-of-paris into what is called plaster of Paris, and all the interstices are to be filled up with the same powder, so that the *glaze*-refracts may no where touch either one another, or the sides of the vessel they are baked in. The vessel is to be then covered down and level, and the fire done the rest of the work; for this is only to be put into a common potter's furnace, and when it has flowed there the final time of the baking the other vessels, it is to be taken out, and the whole contents to be found an impure *glaze*, but converted into a white opaque substance, which is a very elegant porcelain, and has almost the properties of that of China. *Memoirs Acad. Sciences Par. 1735*.

The powder which has ferred out, will do again as well as fresh, and that for a great many times; nay, it seems, ever to elude. The cause of this transformation, says Macquer, is probably that the vitriolic acid of the gypsum quits its basis of calcareous earth, and unites with the alkaline fat and saline earth of the *glaze*, with which it forms a kind of salt or saltless, differing from the calcareous facilities, by the interposition of which matters the *glaze* acquires the qualities of porcelain. Dr. Lewis, from a variety of experiments on the nature, and qualities, and method of producing this porcelain has deduced the following conclusions: 1. Green *glaze* cemented with white sand received no change in a heat below ignition: in a low red-heat, the change proceeded very slowly; but in a strong red-heat, approaching to whiteness, the thickest pieces of *glaze* bottles were thoroughly changed in three hours. 2. The *glaze* sustained the following progression of changes. Its surface first became blue; its transparency was diminished, and when held between the light and the eye, it appeared of a yellowish hue; afterwards it was changed a little way on both sides into a white substance, externally still bluish and as this change advanced still farther and further within the *glaze*, the colour of the vitreous part in the middle approached nearer to yellow: the white crust was of a fine fibrous texture, and the fibres were disposed nearly parallel to one another, and transverse to the thickness of the piece: by degrees the *glaze* became throughout white and fibrous, the external bluishness at the same time going off, and being succeeded by a dull whitish or dun colour: by a still longer continuance in the fire, the fibres were changed gradually from the external to the internal part, and converted into grains; and the texture then was not unlike that of common porcelain. The grains, at first fine and somewhat glossy, appeared afterwards larger and duller, and at length the substance of the *glaze* became porous and friable, like a mass of white sand slightly cohering. 3. Concerning the qualities of the converted *glaze* Dr. Lewis observes, that the whiteness of the internal part was not inferior to that of porcelain, but that its texture was the least regular, that the thick pieces were quite opaque, and that several thin pieces were translucent; that while it remained in a brown state, its hardness became greater than that of *glaze*, or of the common kinds of porcelain: it was capable of sustaining sudden changes of heat and cold better than any porcelain; and in a moderate warm heat, it was soluble into a substance not fibrous, but vitreous and smooth, like white enamel: that when its texture had been coarsely granulated it was now much softer and unshiftable; and, lastly, that while its continuance of a moderate heat, would have become porous and friable, were suddenly exposed to an intense fire, they were rendered remarkably more compact and better; the solidity of some of them being found to be that of any other ware. 4. No difference appeared in the internal colour, hardness, texture, or the regular succession of changes, from the size of different cohering substances, though in external appearances the differences were considerable. All the pieces which had been surrounded with charcoal or with fuel were externally of a very black colour, which did not disappear by exposure to a strong fire during an hour, with free access

of air. Coloured *glazes* and fairs converted into different shades of a brown colour; and white *glazes* gave whitish, greyish, or brown tinge. White fairs, calcined flints, and gypsum gave in general the greenish whiteness, and tobacco-pipe clay the greenish yellowish, and brightens. *Glazes* composed of sands without alkaline salt, *glaze* of lead, *glaze* of iron, *glaze* of copper, *glaze* of silver, *glaze* prepared with calcined flints and a fixed alkaline salt, and even green *glaze* which had been fused together with a ninth part of alkaline salt, suffered none of the above alterations by vitrification. Green bottles and common window *glazes* were most susceptible of these alterations. 6. The changes produced by vitrification could not proceed from any absorption of matter from the containing substance; because no increase of weight was given, and because the same changes were produced upon a piece of *glaze* merely by heat, without any cementing substance. See *Com. Phil. Techn. p. 320-355*. See *Phaet. 1735*.

GLAZING, the refect in the *glaze* state used for melting into a *glaze*. Those for the white *glaze* which are made of a tobacco-pipe clay, brought from the life of Wigan, which is first well washed, then calcined, and afterwards ground to a fine powder in a mill; which being mixed with water, is then trod with the bare feet till it is of a proper consistence, to mould with the hands into the proper shape of the refect. When these are thus made, they are afterwards annealed over the furnace. Those for the green *glaze* work are made of the smoothest, and another sort of clay from Staffordshire; they make these *glazes* as to hold three or four hundred weight of metal. And besides these, they have a small sort called piling pots, which they let upon the larger, and which contain a finer and more nice canal for the small works. Next.

The clay that is used for this purpose should be of the purest and most refractory kind, and well cleaned from all sandy, ferruginous, and pyritous matters; and as this it will be proper to add ground corundum, which sand, calcined flints duly levigated, or a certain proportion of the same clay baked, and pounded not very finely. The quantity of baked clay that ought to be mixed with the crude clay, to prevent the pots from cracking when dried, or exposed to a great heat, is not absolutely determined, but depends on the quality of the crude clay, which is more or less fat. M. D'Arcy, in a memoir on this subject, proposes the following method of determining it: the burnt and crude clay, being mixed in different proportions, should be formed into cakes, one inch thick, and four inches long and wide. Let these cakes be slowly dried, and exposed to a violent heat, till they become so hard and so much contracted in position, and in this state be examined; and the cakes, the best, which has suffered a diminution of its bulk equal only to an eighteenth part, is made of the best proportions. He observes, in general, that most clays require that the proportion of the burnt should be to the fresh as four to five.

GLASS TUBES are of various lengths, diameters, and forms, according to the experimental purposes to which they are applied. It has been observed, that *glass* tubes had before the fire in an horizontal position, and with their extremities supported, have had a rotatory motion about their axis, and also a progressive motion towards the fire, even when their supports are inclining from the fire, so that the tubes will move a little upwards. See *Phil. Trans. N° 476*.

When the progressive motion of the tube is stopped by any obstacle, its motion about its axis will still continue. When the tubes are placed in a nearly upright position leaning to the right hand, the motion will be from east to west; but if they lean to the left, the motion will be from west to east, and the nearer they are placed to the perfectly upright position, the less the motion will be either way.

If the tube be placed horizontally on a *glass* plate, the fragment, for instance, of each wire *glass*, instead of moving towards the fire, will move from it, and about its axis, in a contrary direction to what it had done before; it will recede from the fire and move a little upwards, when the plate inclines towards the fire.

Neither the draught of air up the chimney, nor attraction or repulsion, are the cause of these phenomena. It seems rather owing to the swelling of the tube towards the fire; for allowing four feelings, gravity must pull the tube down, when supported near its extremities horizontally, and a fresh part being exposed to the fire and swelling out again, must fall down again, and so on successively; which will produce a rotatory motion towards the fire.

If the tube be supported by two other tubes, and they be brought next to each other, and to the extremity the sup-

ported

gives them a beauty, which no earthen-ware of our times can attain; it is not only far more durable than our way of doing it with lead, which is apt to crack and fly, both with wet and with heat, but far more fair and wholesome, lead being well known to be a repulsive metal, and its fumes very noxious, there is great reason to suspect that it must be unwholesome when brought to the fire. This ancient process seems to have been done either by the brush, or else by dipping, for both the inside and outside are varnished with equal regularity, and something may be puzzled at as to the materials they used in it from what Pliny has left us. This author occasionally observes, that such earthen ware as was painted with bitumen, never lost its beauty; and afterwards, that it was a custom to cover over whole houses with this sort of glass, which he observes did not only make a smooth coat, but kept out the master of the house or earth, and therefore this could not be likely to crack and fly off like our lead-coats on plates, &c. which is merely a crust laid over them. *Hist. Nat. Collect.* p. 89.

A common stoneware for any kind of earthen ware may be made of white sand forty pounds, of red-lead twenty pounds, of pearl-ash twenty pounds, and of common salt twelve pounds. Powder the sand by sifting it, and then mix it to the other ingredients and grind them together; stir which within four or five times with a moderate heat, and when the mixture is cold, pound it to powder, and when wanted for use temper it with water. The proportion of these ingredients may be occasionally varied. We may observe, in general, that lead ought not to be calcined from the composition of *glaze*, and other fluxes substituted in its stead. See *COLOURS* & *EMAMEL*.

A transparent glaze may be prepared, without lead, by calcining forty pounds of white sand, twenty-five pounds of pearl-ash, and fifteen pounds of common salt; and proceeding as before; and a more perfect transparent glaze may be made of sand forty pounds, of wood-ashes perfectly burnt, fifty pounds, of pearl-ash ten pounds, and of common salt twelve pounds. The following recipes are taken, for the most part, from Knochel, who says, that they are the true secrets used at Delft, and other Dutch manufactories.

GLAZING, black, is made of eight parts of red-lead, iron filings three, copper-ashes three, and sulfur two measures. This, when melted, will make a brown black; and if you want it blacker, add more sulfur to it.

GLAZING, blue, is thus prepared: take lead-ashes, or red-lead, one pound, clear sand, or powdered flint, two pounds, common salt two pounds, white calcined tartar one pound, Venice or other glass half a pound, sulfur half a pound; mix them well together, and melt them the several times, quenching them always in cold water. If you would have it fine and good, it will be proper to put the mixture into a glass furnace for a day or two.

Another blue glaze may be formed of one pound of tartar, a quarter of a pound of red-lead, half an ounce of sulfur, and a quarter of a pound of powdered flint, which are to be sifted and mixed as in the last recipe. Or, take two pounds of calcined lead and tin, one pound of common salt, five pounds of powdered flint, and of sulfur, tartar, and Venetian glass, each one pound. Calcine and melt the mixture as before.

Or, again, take of red-lead, one part, of flint three parts, and of sulfur one part. For a violet blue glaze, take four ounces of tartar, two ounces of red-lead, five ounces of powdered flint, and half a dram of manganese.

GLAZING, brown, is made of red-lead and flint, of each fourteen parts, and of manganese two parts, fused; or, of red-lead twelve parts, and manganese one part, fused. A brown glaze, to be laid on a white ground, may be made of manganese two parts, and of red-lead and white glass, of each one part, twice fused.

GLAZING, green, is made of twelve parts of lead-ashes, and one of white glass.

GLAZING, yellowish. To make gold-coloured glaze, take of litharge three parts, of sand, or calcined flint, one part; pound, and mix these very well together; then run them into a yellow glass with a strong fire. Pound this glass, and grind it into a subtile powder, which mix with a well triturated solution of mercury make it into a paste, which put into a crucible, and cover it with a cover. Give it first a gentle degree of fire; then increase it, and continue it till you have a crust, which will be green. Pound this glass again, and grind it to a fine powder; moisten this powder with some beer, so that by means of an hair pencil you may apply it upon the vessels, or any piece of earthen ware. The vessels thus are primed; covered over with this glaze, must be first well heated, then put under a muffle; and as soon as the glass runs, you must wash them, by holding them over burning vegetables, and take out the vessels.

Mr. Hainthof of Paderburg, who sent this receipt to the Royal Society, says the worst glaze does not come, which is rendered *translucent*, in the Translations. *Phil. Trans.* N^o 465. § 2.

Knochel gives several preparations for a gold-coloured yellow glaze. This may be produced by fusing a mixture of three parts of red-lead, two parts of antimony, and one part of fusion of Mars; by again melting the powdered mass, and repeating the operation four times; or, by fusing four or five times a composition of red-lead and antimony, of each an ounce, and of scales of iron half an ounce; or by calcining and fusing together eight parts of red-lead, six parts of flint, one part of yellow clay, one part of antimony, and one part of white glass. A transparent gold-coloured glaze may be obtained by twice fusing red-lead and white flint, of each twelve parts, and of filings of iron one part.

GLAZING, green, may be prepared of eight parts of litharge, or red-lead, eight parts of Venice glass, four parts of lead-dust, or filings of copper; or, of ten parts of litharge, twelve of flint or pebbles, and one of ss not so, or copper-ashes.

A fine green glaze may be produced by fusing one part of the Bohemian granite, one part of filings of copper, one part of red-lead, and one part of Venetian glass; or, by fusing one part of white glass, the same quantity of red-lead, and also of filings of copper; powdering the mass, and adding one part of Bohemian granite to two parts of the powder. A fine green may be obtained by mixing and grinding together one of the *paste* stannous with equal quantities of the *blue* stannous; and all the flint and filings of green will be laid by varying the proportion of the one to the other, and by the choice of the kind of yellow and blue.

GLAZING, iron-brown, is prepared of fifteen parts of lead-ashes, or red-lead, fourteen of white sand, or flint, and five of calcined copper. This mixture is to be calcined and fused.

GLAZING, iron-colored, is prepared of twelve parts of litharge, eight of flint, six of pebble or flint, and one of manganese.

GLAZING, purple-brass, consists of lead-ashes fifteen parts, clear sand, or powdered flint, eighteen parts, manganese one part, and white glass fifteen measures; to which some add one measure of sulfur.

GLAZING, red, is made of antimony three pounds, litharge, or red-lead, three, and rail of iron, one; grind them to a fine powder. Or take two pounds of antimony, three of red-lead, and one of calcined fusion of Mars, and proceed as before.

GLAZING, red-green, is made of five pounds of lead ashes, one pound of tin-ashes, three pounds of flint, three quarters of a pound of salt, half a pound of tartar, and half a pound of copper-lust.

GLAZING, white. A fine white glaze for earthenware is thus prepared. Take two pounds of lead, and one of tin; calcine them to ashes; of this take two parts, calcined flint, white sand, or broken white glass, one part, and salt one part. Mix them well together, and melt them into a cake for use. The trouble of calcining the tin and lead may be prevented, by procuring them in a pure state.

The white glaze for common ware is made of forty pounds of clear sand, twenty-five pounds of litharge, or lead-ashes, twenty-six of pot-ashes, and ten pounds of salt: these are three times melted into a cake, quenching it each time in clear cold water. Or, it may be made of fifty pounds of clean sand, twenty of lead-ashes, thirty of wood-ashes, and twelve of salt.

A very fine white glaze may be obtained by calcining two parts of lead, and one part of tin; and taking one part of this mass, and of flint and common salt, of each one part, and fusing the mixture. See *DEGLAZING*.

A white glaze may be prepared by mixing one hundred pounds of MASTICE, fifty pounds of red-lead, twenty pounds of calcined tin or potty, and ten pounds of common salt, and calcining and powdering the mixture several times.

GLAZING, yellow, is prepared of red-lead, three pounds; calcined antimony and tin, of each two pounds; or, according to some, of equal quantities of the three ingredients. These must be melted into a cake, then ground fine; and this operation repeated several times; or, it may be made of fifteen parts of lead-ore, three parts of litharge of silver, and fifteen parts of flint.

A fine yellow glaze may be produced by mixing five parts of red-lead, two parts of powdered bricks, one part of sand, one part of the white glaze, and two parts of antimony, calcining the mixture and then fusing it. Or, take four parts of white glass, one part of antimony, three parts of red-lead and one part of iron scales, and fuse

fule the mixture: or, fule fifteen parts of Rinta, one part of iron-filings, and twenty-four parts of litharge. A light yellow glazary may be produced with ten parts of red-lead, three parts of antimony, and three of glaz, and two parts of calcined tin. See *Gall-coloured GLAZING*.

GLAZING, *circus-galvus*, is made of six parts of red-lead, seven parts of fine red brick-dust, and two parts of antimony. This mixture must be calcined day and night for the space of four days, in the ash-hole of a glass-blows furnace, and at last urged to fusion.

GLAZING of Delfware. See *DELFT-WARE*.

GLAZING of porcelain. See *PORCELAIN*.

GLAZING of glassware, and painted glass. See *POTTERY*.

GLEAD, or GLADE, a name used in the northern parts of the kingdom for the wilson, or RITE.

GLEAM is popularly used for a RAY or beam of light. Among falconers, a hawk is said to *gleam*, when the call or turns up fish from the gorg.

GLANING, the act of glazing, or picking up the ears of corn left behind after the field has been reaped, and the crop carried home.

By the customs of some countries, particularly those of Meian and Etampes, all farmers, and others are forbidden, either by themselves or servants, to put any cattle into the fields, or prevent the *glazing* in any manner whatever, for the space of twenty-four hours after the turning of the corn; on penalty of confiscation, &c.

GLEBA alone, a name by which some call the yellowish white YEPHOD.

GLEBE, GLEBA, in *Natural History, Geography*, &c. a solid or piece of stone or earth, frequently containing some metals, or minerals.

The *glebes* are carried to the forge to be washed, purified, and melted, &c.

GLEBE, or *GLEBE-LAND*, is properly used for church-land. Derived from *gleba* and *terre*.

Glebe-land is most commonly used for land belonging to a parish-church, beside the tithes.

Thus, *Landwood: Gleda de terra in qua existit unum aliquod: generaliter tamquam per se, vel per terra culta*. Though in the most general, and extensive use of the word, *glebe* is applicable to any land or ground belonging to any benefice, vicar, manor, inheritance, or the like.

If any person, vicar, &c. hath caused any of his *glebe* lands to be enclosed and sowed at his own costs, with any corn or grain, the incumbents may derive all the profits and gains growing upon the said *glebe* by will. Stat. 28 H. 8. cap. 11. and if a person sows his *glebe* and dies, the executor shall have the corn sown by the testator. But if a *glebe* be in the hands of a tenant, and the parson dies after severance of the corn, and before his rent due, it is said, neither the parson's executor nor his successor can claim the rent, but the tenant may retain it and all the crop, which there by a special covenant for the payment to the parson's executor proportionably, &c. Wood's Inst. 163.

GLEBE, addit. In the civil law, *glebes* were said to be annexed to the *glebe*, i. e. they went with it, were sold with it, &c.

The right of *PARAVANGA* should be annexed to a *glebe*.

GLECHOMA, in *Botany*, the name by which Linnaeus calls GROUND-IVY.

GLECHOMITES, a name given by the ancient Physicians, to a sort of wine impregnated with penny-royal, much recommended in all obstructions. It takes its name from *glechos*, the Greek name of *RUSSA* *royal* or *galegum*.

GLEDE. See *GLEAD*.

GLADISTIA, in *Botany*. See *HONEY LEAF*.

GLEET, in *Medicine*, a flux of thin humour from the urethra.

A *gleet*, or gonorrhoea simplex, often succeeds the cure of a gonorrhoea viridiana; and sometimes remains obdurate, even after the use of a salivation.

The *gleet* may happen either from a too great relaxation of the glands of the urethra, or from a corruption or exaltation of them. It appears most frequently after a gonorrhoea has been of long standing, or ill managed in the cure; as by the use of acrid or corroding injections, and the like.

The glands may here also happen to be ulcerated by the matter of the running, which is often sharp and corrosive enough for that purpose.

When the discharge proves very obdurate, and recedes late or no check from stringent remedies, there is ground to suspect that it is owing to ulcers; but if it is inconstant and only occasional, when the patient is stimulated by labouring hard, or upon straining to go to stool, it is chiefly owing to relaxation.

A *gleet* is distinguished from a gonorrhoea simplex, not only by the colour and consistence of the matter evacuated, but also by the manner wherein it comes away;

the matter of a *gleet* comes away as well at one time as another; but that of a gonorrhoea simplex chiefly in erections, and when the patient goes to stool. The matter of a *gleet* is commonly brownish, but that of a gonorrhoea simplex is white. Add, that the commencement of a true *gleet* is unattended with weakness, or other ill consequences and disagreeable symptoms; nor does it unfit men for procreation, as a gonorrhoea simplex will. In the cure of a *gleet* proceeding from relaxation, the principal design is to brace and to restore a proper degree of tension to the debilitated and relaxed vessels.

For this purpose, besides the medicines that are recommended in the last stage of the GONORRHOEA, the patient should have recourse to stronger and more powerful stimulents, as the Peruvian bark, alum, nitric, callos, mercurial, bitters, balsamum, &c. The bark may be continued with other medicines in the following manner: Take of Peruvian bark bruised, six drams; of fresh galls bruised, two drams; boil them in a pound and a half of water to a pound, and add to the strained liquor three ounces of the simple tincture of the bark. A small tumbler full of this may be taken three times a day, adding to each cup fifteen or twenty drops of the acid spirit of vitriol. This cure may be promoted by appropriate washings, such as are recommended under GONORRHOEA, with the addition of a few grains of alum, or white vitriol. The cold bath should be constantly used every morning for three or four weeks, unless the use of it be unsafe on account of the patient's full habit, which may be remedied by purging and bleeding, or an unusual dose of the viscers. The diet is the same as in the last stage of the gonorrhoea, and the drink should be Spa, Primont, or Bristol waters, occasionally mixed with a small quantity of claret or red wine. If there be reason to apprehend, from the failure of this course of regimen and medicines, or other circumstances, that the *gleet* proceeds from ulcers, recourse must be had to mercury and such medicines as tend to correct any acid miasm of the juices; as the decoction of tartaric acid, salutaria, and the like. Mercurial injections have proved effectual in very obdurate cases; and they have been recommended to be joined with scabiminate and other acrid mixing medicines. Dr. Chapman recommends pills made of calomel and Venice turpentine, in the proportion of half a dram of the former to half an ounce of the latter, which may be formed into five pills and five or six of them taken night and morning, accompanied with a decoction of quassum or tartaric acid. The last kind of remedy is preferred for the cure of ulcers in the urinary passage after the SUPPURATION. Barthe's Disp. Med. p. 245, &c.

GLENE, *Glenn*, properly signifies the cavity or socket of the eye.

GLUTE is more frequently used by anatomists for the shallower cavities of bones, into which some other bone is received and articulated.

By which it is hands distinguished from *cava* or *acetabulum*, which is a deeper cavity, intended by nature for the like purpose.

GLENOIDES, an appellation given to the two cavities in the lower part of the first vertebra of the neck.

The word is compounded of *glens*, and *idea* from *form*.

GLESUM, or *GLASSUM*, in *Natural History*, a name given by many of the ancients to the common yellow amber or succinum. The word seems to have been originally German; and to have been adopted by the Romans in their conquests in that part of the world. They seem to have used the word in general for any transparent substance, and therefore to have applied it to amber as a transparent stone. The island Austravia of the Germans, afforded a very great quantity of this amber on its shores, and the Roman soldiers thence gave it the name of *GLASSARIA*. This is a proof of the word *glens* being received into common use as the name of *AMBER*.

GLEUCINUM, a term used by the old Greek writers, to express a composition made of the oil of unripe olives, in which there were infused ichthium, spikenard, and many other of the aromatic drugs, with a considerable quantity of melle; all these were put together into a vessel, which was surrounded with the pelting of grapes, the fermentation of which gave it a gentle heat, and it was left thus thirty days, being well stirred about every day; at the end of this time it was strained off, and the clear oil reserved for use. It was extremely warming, emollient, and relaxing, and was used externally in many cases.

GLYCERHIZA, or *GLYCERYHIZA*. See *LICORICE*.

GLINUS, in *Botany*, a genus of the *diandria polygynia* class; the calyx of which consists of five leaves; it has no corolla; the seedvessels are formed by blind bristles; and the fruit is a pentagonal, five-celled, five-valved, polyperous capsule.

GLINES, in *Ichthyology*, a name by which Bellonius and some other authors have called a small sea fish, more commonly known by the name of the *DRACONETUS*.

GLIS. In the common acceptation of the word, this only signifies the dormouse: but Linnæus has used *glis* in a larger sense; and, in his system of Zoology, makes it the name of the fourth order of the *MAMMALIA* class of animals. The characters of the creatures of this class are, that they have only two fore-teeth in each jaw, they have no *denta canina*, or dog-teeth; and the feet have toes, and are formed for leaping when they run. The animals of this class are the several species of the porcupine, the bat, the squirrel, the beaver, the mout, and *NOCTUR* or American bat.

GLIS is commonly used as the name of an animal of the mouse kind, but so differently described, by different authors, and so imperfectly and erroneously by many, that it is a question, whether we can properly call any known animal by the name.

Geiser, describing it by hearsay, says, that it is larger than a squirrel, and either black or brown on the back, and white on the belly; its tail short, and its general figure somewhat approaching to that of the bear. In the Linnæan system it is the grey squirrel with a white belly.

GLIS-ULIANUS, the flying-dormouse, in *Zoology*, the name of an animal, properly of the *vespertilio* or bat kind; it is distinguished by Linnæus by the name of *spasma* or *vespertilio oculatus uola fatidat alor datus*.

GLISCHROCOLOUS, an epithet used by some writers to express excrement which are at once viscid and very highly fated with gall.

GLISCHROMICTHES, in *Natural History*, the name of a genus of compound earths. The word is derived from *γλίσχρος*, *glischros*, and *μικτός*, *miktos*. The bodies of this genus are loams composed of sand and a more viscid clay, and are of a tough and firm texture.

The earths of this genus are used in making bricks, and on some other occasions, and are of several distinct species.

GLISOMARGA, a word used by some authors as a name for *CHALK*.

GLISSA, in *Ichthyology*, the name of a sea fish of the tenney kind, but of a perfectly smooth skin, and wholly free from scales. It usually grows to the length of two cubits, and the thickness of a man's body; it is of a very round body, and has very rough scales, but no distinct teeth; its tail is forked, but not so arched, or lunate, as that of the tunny; it lives in deep water, and is a fish of very delicate taste. Geiser. De Pisc. p. 158.

GLISTER. See *CHLATER*.

GLIZADE, in *Erving*, is an operation performed by dextrously making your sword slip along your adversary's blade, and forming at the same time your exertions, &c.

GLOBE, in *Geometry*, a round or spherical body, more usually called a *SPHERE*.

The earth and water together, are supposed to form a globe: hence called the *terrestrius globe*.

The planets, both primary and secondary, are supposed, as well as our earth, to be solid globes.

The earth is, in a particular sense, called the *globe*, or *globe of earth*; though it is now well known that this is not its true figure. See *Figure of the EARTH*.

GLOBE, *resistant* of *s*. See *RESISTANCE*.

GLOBE is more particularly used for an artificial sphere of metal, plaiter, paper, or some other matter; on whose convex surface is drawn a map, or representation, either of the earth or heavens, with the several circles conceived thereon.

GLOBES are of two kinds, *terrestrial* and *celestial*; each of very considerable use; the one in astronomy, and the other in geography, to perform many of the operations thereof in an easy sensible manner, so as to be conceived without any knowledge of the mathematical grounds of those arts.

The fundamental parts, common to both globes, are an axis, representing that of the world, and a spherical shell or cover, which makes the body of the globe, on whose external figure the representation is drawn. Globes, we have observed, are made of divers materials, viz. silver, brass, paper, plaiter, &c. Those commonly used are of plaiter and paper; the construction whereof is as follows.

GLOBES, *construction of*. A wooden axis is provided, somewhat less than the intended diameter, of the globe; and into the extremes hereof, two iron wires are driven for poles; this axis is to be the beam or basis of the whole structure.

On the axis are applied two spherical, or rather hemispherical caps, formed on a kind of woulen mould or block. These caps consist of pasteboard or paper, laid one way after another, on the mould, to the thickness of a given piece; after which, having stood to dry and em-

body, making an incision along the middle, the two caps, thus parted, are slipped off the mould.

They remain now to be applied on the poles of the axis, as before they were on that of the mould; and to fit them in their new place, the two edges are lown together with packthread, &c.

The rudiments of the globe thus laid, they proceed to strengthen and make it smooth and regular. In order to this, the two poles are lapped in a mealline semi-circle of the size intended; and a kind of plaiter, made of whitening, water, and glue, heated, moisted, and incorporated together, is dabbed all over the paper surface. In proportion as the plaiter is applied, the ball is turned round in the semi-circle, the edge whereof presses off whatever is superfluous, and beyond the due dimension, leaving the rest adhering in places that are smooth of it. After such application of plaiter, the ball stands to dry; which done, it is put again in the semi-circle, and fresh matter applied: thus they continue alternately to apply the composition, and dry it, till such time as the ball every-where accurately touches the semi-circle: in which state it is perfectly smooth, regular, firm, &c.

The ball thus finished, it remains to paste the map or description thereon: in order to this, the map is projected in several gores or gullets, all which join accurately on the spherical surface, and together cover the whole ball. To direct the application of these gores, lines are drawn by a semi-circle on the surface of the ball, dividing it into a number of equal parts corresponding to those of the gores, and subdividing those again uniformly to the lines and divisions of the gores.

The papers thus pasted on, there remains nothing but to colour and illuminate the globe, and to varnish it, the better to resist dust, moisture, &c.

The globe itself thus finished, they hang it in a brass meridian, with an hour circle, and quadrant of altitude, and thus fit it into a wooden horizon.

GLOBES, *description of the*. The things common to both globes are either delineated on the surface, or added as appendages without it.

Without the surface are, 1. The two poles, whereon the globe is turned, representing those of the world: See *POLE*. 2. The brazen meridian, which is divided into degrees, and passes through the poles. 3. The wooden horizon, whose upper side represents the horizon, and is divided into several circles, the innermost whereof contains the twelve signs of the zodiac, subdivided into their degrees; the next the Julian; and the third the Gregorian calendar: withoutside of all these, are drawn the points of the winds. 4. A brass quadrant of altitude, divided into 90 degrees, to be fastened on the meridian at the distance of 90 degrees from the horizon. 5. The hour-circles, divided into twice twelve hours, and fitted on the meridian round the poles, which carry an index pointing to the hour. A mariner's compass is sometimes added on the bottom of the frame, and sometimes a semi-circle of position.

On the surface are delineated, 1. The equinoctial line, divided into 360 degrees, commencing from the vernal intersection. 2. The ecliptic, divided into twelve signs, and these subdivided into degrees. 3. The zodiac. 4. The two tropics. And, 5. The polar circles. All which see under their proper articles.

What else belongs to globes, either as to construction or description, is different, as the globe is either *celestial* or *terrestrial*.

Our common globes, though instructive instruments for explaining the first rudiments of geography and the spherical doctrine of astronomy, yet labor under several defects; as they do not show how the phenomena, illustrated by them, arise from the motion of the earth, which is the principal thing beginners especially should have in view; and as they are only formed for the present age, and do not serve the purposes of chronology and history, which they might be made to do, if the poles, whereon they turn, were contrived to move in a circle round those of the ecliptic, according to its present obliquity.

Mr. John Senex, F. R. S. invented a contrivance for remedying these defects, by fixing the poles of the diurnal motion to two shoulders or arms of brass, at the distance of 23° 44' from the poles of the ecliptic: These shoulders are strongly fastened at the other end to an iron axis, which passes through the poles of the ecliptic, and is made to move round with a very stiff motion; so that, when it is adjusted to any point of the ecliptic, which the equator is made to intersect, the diurnal motion of the globe on its axis will not be able to disturb it. When it is to be adjusted for any time, past or future, one of the brazen shoulders is brought under the meridian, and held fast to it with one hand, whilst the globe is turned about with the other, so that the point of the ecliptic, which the equator is to intersect, may pass under a dex-

gree of the brazen meridian; then, holding a pencil to that point, and turning the globe about, it will describe the equator according to its position at the time required, and transferring the pencil to $23\frac{1}{2}^{\circ}$ and $66\frac{1}{2}^{\circ}$ on the brazen meridian, the tropic and polar circles will be so described for the same time. By this contrivance, the celestial globe may be so adjusted, as to exhibit not only the risings and settings of the stars, in all ages and in all latitudes, but likewise the other phenomena that depend upon the motion of the diurnal axis round the annual axis. Smith's celestial globe, especially the two greatest, of fourteen and twenty-eight inches in diameter, have been constructed on this principle; so that, by means of a nut and screw, the pole of the equator is made to revolve about the pole of the ecliptic. Phil. Trans. N^o 447. p. 201, 203. or Martyn's Abr. vol. viii. p. 217. and 493. art. 18. in Phil. Trans. vol. xlv. p. 290.

Mr. Joseph Harris, late assay-master of the mint, contrived to remedy the former of the defects above mentioned, by placing two horary circles under the meridian, one at each pole: these circles are fixed tight between two brass collars placed about the axis, so that when the globe is turned they are carried round with it, the meridian serving as an index to cut the horary divisions.

The globe, in this state, serves readily for solving problems in north and south latitudes, and also in places near the equator; whereas, in the common construction, the axis and horary circle prevent the brass meridian from being moveable quite round in the horizon. This globe is also adapted for shewing how the vicissitudes of day and night, and the alteration of their lengths, are really occasioned by the motion of the earth: for this purpose, he divides the brass meridian, at one of the poles, into months and days, according to the sun's declination, reckoning from the pole. Therefore, by bringing the day of the month to the horizon, and rectifying the globe according to the time of the day, the horizon will represent the circle separating light and darkness, and the upper half of the globe the illuminated hemisphere, the sun being in the zenith. Mr. Harris also gives an account of a cheap machine for shewing how the annual motion of the earth in its orbit causes the change of the sun's declination, without the great expence of an orrery. Phil. Trans. N^o 456. p. 321, &c. or Martyn's Abr. vol. viii. p. 352.

The late Mr. George Adams, mathematical instrument-maker to his majesty, has made some useful improvements in the construction of the globe. His globe, like others, are suspended at their poles in a strong brass circle, and turn therein upon two iron pins, which are the axis. They have, besides, a thin brass semi-circle, moveable about the poles, with a small thin, sliding circle upon it. On the terrestrial globe, the thin brass semi-circle is a moveable meridian, and its small sliding circle the visible horizon of any particular place to which it is set. On the celestial globe, the semi-circle is a moveable circle of declination, and in small annexed circle, an artificial sun or planet. Each globe hath a brass wire circle, placed at the limits of the twilight, which, together with the globe, is set in a wooden frame, supported by a neat pillar and claw, with a magnetic needle at its base. On the terrestrial globe, the division of the earth into land and water is laid down from the latest discoveries: there are also many additional circles, as well as the rhumb-lines, for solving all the necessary geographical and nautical problems. On the celestial globe, all the southern constellations, lately observed at the Cape of Good Hope by Mr. de la Caille, and all the stars in Mr. Flamsteed's British Catalogue, are accurately laid down, and marked with Greek and Roman letters of reference in imitation of Bayer. Upon each side of the ecliptic are drawn eight parallel circles, at the distance of one degree from each other, including the zodiac; and these are crossed at right angles with segments of great circles at every fifth degree of the ecliptic, for the more readily noting the place of the moon, or of any planet upon the globe. The author has also inserted, from Ulugh Beigh, printed at Oxford in 1695, the Mansions of the Moon of the Arabian Astronomers, to call, because they observed the moon to be in or near one of these every night during her monthly course round the earth, to each of which the Arabian characters are fixed. On the strong brass circle of the terrestrial globe, and about $23\frac{1}{2}^{\circ}$ on each side of the north-pole, the days of each month are laid down according to the sun's declination: and this brass circle is so contrived, that the globe may be placed with the north and south poles in the plane of the horizon, and with the fourth pole elevated above it. The equator, on the surface of either globe, serves the purpose of the horary circle, by means of a semi-circular wire placed in the plane of the equator, carrying two indices, one

of which is occasionally to be used to point out the time. For a further account of these globes, with the method of using them, the reader may consult Adams's Treatise on their Construction and Use, &c. 1769.

GLOBE, artificial, is an artificial sphere, on whose convex surface the fixed stars are laid down, at proportionable distances, together with the principal circles of the sphere.

The surface of the celestial globe may be esteemed a just representation of the concave expanse of the heavens, notwithstanding its convexity; for if the eye were placed in the centre of it, and the globe made of glass, the stars that are drawn upon it would appear in a concave surface, exactly corresponding to those in the heavens.

The use of these globes is to exhibit the phenomena of the motions of the sun and stars, in an easy and obvious manner; which, though somewhat inaccurate, is yet exact enough for the common uses of life, and may save the trouble of trigonometrical calculation.

To exhibit the stars, circles, &c. on the surface of a given sphere or ball, and fit for the use of astronomy.

1. Assume any two points diametrically opposite to each other, as P and Q (Tab. Astronomy, fig. 38.) and in these fix up axes, P A and Q C, for the ball to turn round on. The points P and Q, or A and C, will exhibit the poles of the world.

2. Divide a brazen circle A B C D into four quadrants, A E, E C, C F, and F A; and subdivide each quadrant into 90 degrees, numbered from the points E and F, towards the poles A and C.

3. Inclose the globe in this circle, as in a meridian, at the points A and C, so that it may freely turn therein.

4. Apply a style or pin to the surface of the globe, in the first degree of the meridian, and turn the ball round; by this means will a circle be described on the surface representing the equator to be divided into degrees.

5. From the pole of the world P towards M, and from the other pole C towards N, number 23 degrees; the points M and N will be the poles of the ecliptic.

6. Apply a style to the meridian, in the point M, and turn the globe round; by this rotation will the arctic polar circle be described; and after the same manner is the antarctic polar to be described about the point N.

7. Number 23 deg. from the equator towards the poles P and Q, and note the points H and I; then applying a style to the meridian, as before, two circles will be described parallel to the equator, whereof that drawn through H will be the tropic of Cancer, and the other through I the tropic of Capricorn.

8. Hang the globe within the meridian, in the poles of the ecliptic, as before in the poles of the world; and applying a style to E, turn it round: by this means will the ecliptic be delineated, which remains to be divided into twelve signs; and each of these, again, divided into thirty degrees.

9. While the globe remains thus suspended, bring the degree of longitude of any star under the meridian; and in the meridian, number as many degrees towards the pole as is the degree of latitude of the place: the point of intersection is the place of that star on the surface of the globe. After the like manner may the place of the star be determined from the right ascension and declination given, the globe being supposed suspended from the poles of the world, or the equator.

10. All the stars of a constellation that laid down, the figure of the constellation is to be designed; after which it may either be coloured or engraved.

11. Place the globe with the meridian, in a wooden frame or horizon, D B L, supported on four feet, in such manner as to be divided thereby into two hemispheres, and that the pole A may be raised or depressed at pleasure.

12. On the limb or edge of the horizon describe a circle which divide into 360 degrees, and insert the calendars and winds.

13. Lastly, To the pole A fit a brazen circle, divided into twenty-four horary parts, and numbered twice twelve, so that the line of division of XII. may be in the plane of the meridian, on either side the pole; and on the pole itself apply an index, to turn round with the globe. See Horary CIRCLE. Thus is the globe complete.

It may be here observed, that as the longitude of the stars is continually increasing, a common globe does not remain of perpetual use: but the increase in seventy-two years only amounting to a degree, the whole will make no considerable error in a hundred years; the design of a globe being only to represent things something near the truth.

GLOBE, to make a celestial. This method is that the most frequently used; and we only premised the former as being the most easily conceived, and leading more naturally to this.

1. From the given diameter of the globe, find a right line

line A B, fig. 59. *n.* 2. equal to the circumference of a great circle, and divide it into twelve equal parts.

2. Through the several points of division, 1, 2, 3, 4, &c. with the interval of 10 of them, describe arches, mutually intersecting each other in D and E: these figures or pieces, duly pasted or joined together, will make the whole surface of the globe.

3. Divide each part of the right line A B into thirty equal parts, so that the whole line A B, representing the periphery of the equator, may be divided into 360 degrees.

4. From the poles D and E, fig. 60. with the interval of 23 $\frac{1}{2}$ deg. describe arches *a b*; these will be twelfth parts of the polar circles.

5. After the like manner, from the same poles D and E, with the interval of 66 $\frac{1}{2}$ deg. reckoned from the equator, describe arches *c d*; these will be twelfth parts of the tropics.

6. Through the degree of the equator *a*, corresponding to the right ascension of any given star, and the poles D and E, draw an arch of a circle, and taking in the compasses the complement of the declination from the pole D, describe an arch, intersecting it in *i*; this point *i* will be the place of that star.

7. All the flux of a constellation being thus laid down, the figure of the constellation is to be drawn according to Bayer, Hevelius, or Flamsteed.

8. Lastly, after the same manner are the declinations and right ascensions of each degree of the ecliptic *d g* to be determined.

9. The surface of the globe thus projected on a plane is to be engraven on copper, to save the trouble of doing this over again for each globe.

10. A ball, in the mean time, is to be prepared of paper, plaister, &c. after the manner above directed, and of the intended diameter of the globe: on this, by means of a semi-circle and style, is the equator to be drawn; and through every 30th degree a meridian. The ball thus divided into twelve parts, corresponding to the segments before projected, they are to be cut from the printed paper, and pasted on the ball.

11. Nothing now remains but to hang the globe, as before, in a brazen meridian and wooden horizon; to which may be added, a quadrant of altitude H I, fig. 61. made of brass, and divided in the same manner as the ecliptic and equator.

If the declinations and right ascensions of the stars be not given, but their longitudes and latitudes in lieu thereof, the surface of the globe is to be projected after the same manner as before; except that, in this case, D and E, fig. 59. are the poles of the ecliptic, and *sh* the ecliptic itself; and that the polar circles and tropics, with the equator *g h*, and the parallels thereof, are to be determined from their declinations.

One of the fullest catalogues of the stars is that of Mr. Flamsteed; wherein the right ascensions and declinations, as well as the longitudes, latitudes, &c. are every-where expressed.

GLOBE, use of the ecliptic. The use of this instrument is very extensive; scarce any thing in the spherical astronomy but may be exhibited thereby.

The principal points are contained in the following problems, with their solution; which will let the reader enough into the nature and reason of this noble instrument, to apply it, of his own accord, in any other cases.

To find the right ascension and declination of a star, represented on the surface of the globe. Bring the star to the graduated side of the brazen meridian; then the number of degrees intercepted between the equator, and the point of the meridian cut by the star, gives its declination; and the degree of the equator which comes under the meridian, together with the star, is its right ascension.

To find the longitude and latitude of a star. Apply the centre of the quadrant of altitude over the pole of the ecliptic in the same hemisphere with the star, and bring its graduated edge to the star: the degree on the quadrant cut by the star is its longitude, reckoned from the ecliptic; and the degree of the ecliptic cut by the quadrant is its latitude.

To find the sun's place in the ecliptic. Seek the day of the month in the proper calendar on the horizon, and against the day in the circle of signs is the sign and degree the sun is in for that day: this done, find the same sign upon the ecliptic, on the surface of the globe; this is the sun's place for that day.

To find the declination of the sun. The sun's place for the day given being brought to the meridian, the degrees of the meridian intercepted between the equinoctial and that place, are the sun's declination for that day at noon.

To find the place of a planet, with its right ascension and declination; its longitude and latitude for the time being

given. Apply the centre of the quadrant of altitude on the pole of the ecliptic (the pole, we mean, of the same denomination with the latitude), and bring it to the given longitude in the ecliptic: this point is the planet's place; and bringing it to the meridian, its right ascension and declination will be found, as already shewn of a star.

To rectify the globe, or adjust it to the place, &c. so as it may represent the present state or situation of the heavens.

1. If the place be in north latitude, raise the north pole above the horizon; if in south, raise the south pole; till the arch intercepted between the pole and horizon be equal to the given elevation of the pole. 2. Fix the quadrant of altitude on the zenith, i. e. on the latitude of the place. 3. By means of a compass or meridian line, place the globe in such a manner as that the brazen meridian may be in the plane of the terrestrial meridian.

4. Bring the degree of the ecliptic the sun is in to the meridian, and let the horary index to twelve: thus will the globe exhibit the face of the heavens for the noon of that day. 5. Turn the globe till the index come to any other given hour: thus will it shew the face of the heavens for that time.

To know all the stars and planets by means of the globe.

1. Adjust the globe to the state of the heavens for that time. 2. Look on the globe for some one star which you know; e. g. the middlemost star in the tail of the great bear. 3. Observe the positions of the other more conspicuous stars in the same constellation; and, by transferring the eye from the globe to the heavens, you will easily note the same there. 4. After the same manner may you proceed from this to the neighbouring constellations, till you have learned them all.

If the planets be represented on the globe, after the manner above described, by comparing them with the neighbouring stars you will likewise know the planets.

To find the sun's oblique ascension, his eastern amplitude and azimuth, with the time of rising.

1. Rectify the globe for the hour of twelve, and bring the sun's place to the eastern side of the horizon: then the number of degrees intercepted between that degree of the equator now come to the horizon and the beginning of Aries, is the sun's oblique ascension. 2. The degrees on the horizon, intercepted between the east point thereof and the point wherein the sun is, is the oblique or rising amplitude. 3. The hour, pointed to by the index, is the time of the sun's rising. 4. Turning the globe till the index points to the present hour, lay the quadrant to the sun's place; the degree cut by the quadrant, in the horizon, is the sun's azimuth.

To find the sun's oblique descension, western amplitude, and azimuth, with the time of setting. The solution of this problem is the same with that of the former; excepting that the sun's place must be here brought to the western side of the horizon, as in the former it was to the eastern.

To find the length of day and night. 1. Find the time of the sun's rising, which being numbered from midnight, the double thereof gives the length of the night. 2. Subtract the length of the night from the whole day, or twenty-four hours, and the remainder is the length of the day.

To find the rising, setting, and culminating of a star; its continuance above the horizon for any place and day; together with its oblique ascension and descension, and its eastern and western amplitude and azimuth.

1. Adjust the globe to the state of the heavens at twelve o'clock that day. 2. Bring the star to the eastern side of the horizon: thus will its eastern amplitude and azimuth, and the time of rising, be found, as already taught of the sun. 3. Bring the same star to the western side of the horizon: thus will the western amplitude and azimuth, and the time of setting, be found. 4. The time of rising, subtracted from that of setting, leaves the continuance of the star above the horizon. 5. This continuance above the horizon, subtracted from twenty-four hours, leaves the time of its continuance below the horizon. 6. Lastly, the hour to which the index points, when the star is brought to the meridian, gives the time of its culmination.

To find the altitude of the sun, or a star, for any given hour of the day or night.

1. Adjust the globe to the position of the heavens, and turn it till the index point at the given hour. 2. Fix on the quadrant of altitude, at 90 degrees from the horizon, and bring it to the sun's or star's place: the degrees of the quadrant, intercepted between the horizon and the sun or star, is the altitude required.

The altitude of the sun by day, or of a star by night, being given, to find the time of that day or night. 1. Rectify the globe as in the preceding problem. 2. Turn the globe and quadrant, till such time as the star, or degree of the ecliptic the sun is in, cut the quadrant in the given de-

gree of altitude; then does the index point at the hour sought.

The azimuth of the sun or a star given, to find the time of the day or night. Rectify the globe, and bring the quadrant to the given azimuth in the horizon; turn the globe, till the star come to the fame: then will the index shew the time.

To find the interval of time between the risings of two stars, or their culminations. 1. Raise the pole of the globe to many degrees above the horizon, as is the elevation of the pole of the place. 2. Bring the first star to the horizon, and observe the time the index points to. 3. The same do by the other star: then subtracting the former time from the latter, the remainder is the interval between their risings.

After the like manner is the interval between two culminations found, by bringing both stars to the meridian. *The day of the month being given, to find when any star will come to the meridian.* Rectify for the sun's place; turn the globe till the given star comes to the meridian: then the index will point to the time sought.

To find when a given star will come to the meridian, at any given hour of the night. Bring the given star to the meridian; set the index to twelve at noon; then turn the globe callward, till the index points to an hour as far distant in the forenoon from twelve as the given hour is in the afternoon; observe the degree of the ecliptic then at the meridian, over against which degree, in the calendar, is the day of the month, when the given star will be upon the meridian at the given hour.

By observation of a star upon the meridian, to find the hour of the night. Rectify for the latitude and the sun's place; bring the given star to the meridian, and the index will shew the hour of the night.

To find the beginning and ending of the eclipses, or transits.

1. Rectify the globe, and set the index to the twelfth hour, the sun's place being in the meridian. 2. Note the sun's place, and turn the globe westward, all also the quadrant of altitude, till the point opposite the sun's place cut the quadrant of altitude in the eighteenth degree above the horizon: the index will then shew the time when the twilight commences in the morning. 3. Taking the point opposite to the sun, bring it to the eastern hemisphere, and turn it, till it meet with the quadrant of altitude in the eighteenth degree: then will the index shew the time when the twilight ends.

To explain the phenomena of the horreum-moon by the globe. See Moon.

GLOBE, TERRESTRIAL, is an artificial sphere, on whose surface are delineated the principal places of the earth, in their proper situations, distances, &c. together with their circles imagined on the surface of the terrestrial sphere. The use of the terrestrial globe is to exhibit the several affections and phenomena of the different places of the earth, depending on magnitude, &c. in an easy, obvious manner, without the trouble of trigonometrical calculation.

GLOBE, IS CONSTRUCTED A TERRESTRIAL. The construction of a terrestrial globe, whether of metal, plaster, paper, &c. is the same as that of a celestial. The same circles are delineated on both: and as for the places, viz. cities, towns, &c. they are laid down from the longitudes and latitudes given, as the stars are from their right ascensions and declinations.

Hence all problems, depending on the circles, may be equally wrought on either globe; as the ascensions, descensions, amplitudes, azimuths, tilings, settings, altitudes, &c. of the sun's lengths of day and night; hours of the day and night; crepuscula, &c.

We shall here, therefore, only give what is peculiar to the terrestrial globe.

GLOBE, USE OF THE TERRESTRIAL. *To find the longitude and latitude of any place delineated on the globe.* Bring the place to the graduated side of the brass meridian; the degree of the meridian it cuts is the latitude required; and the degree of the equator, at the same time under the meridian, is the longitude required.

The longitude and latitude given, to find the place on the globe. Seek, in the equator, the given degree of longitude, and bring it to the meridian; then count from the equator on the meridian the degree of latitude given, towards this or that pole, as the latitude is either north or south: the point under this is the place required.

The hour being given at any place, to find what hour it is in any other part of the world. Bring the given place to the meridian, and set the hour-index to the given hour; then by turning the globe, bring any place to the meridian, and the index will point to the hour of that place.

To find the antipodes, pericci, and the antipodes of any place. 1. The given place being brought to the meridian, count as many degrees on the meridian from the equator to-

wards the other pole: the point which is thus arrived at is the place of the antipodes. 2. Note the degree of the meridian over the given place and its antipodes, and turn the globe till the opposite degree of the equator come under the meridian; or, which amounts to the same, till the index, which before stood at twelve, come to the other twelve: then will the place, corresponding to the former degree, be the pericci; and the latter, that of the antipodes.

To find what place of the earth the sun is vertical to at any time assigned. 1. Bring the sun's place found in the ecliptic to the meridian, and the index to the hour of twelve, noting what point of the meridian corresponds thereto. 2. If the given hour be before noon, subtract it from twelve hours, and turn the globe towards the west, till the index point at the hours remaining: thus will the place required be under the point of the meridian before noted. 3. If the hour be after noon, turn the globe in the same manner towards the west, till the index points at the given hour: thus, again, will the place required be found under the point of the meridian before noted.

If, at the same time, you note all the places which are under the same half of the meridian with the place found, you will have all the places to which the sun is then in the meridian; and the opposite half of the meridian will shew all the places in which it is then mid-night.

A place being given in the torrid zone, to find the two days in the year wherein the sun is vertical to the same. 1. Bring the given place to the meridian, and note the degree of the meridian corresponding thereto. 2. Turn the globe about, and note the two points of the ecliptic passing through that degree. 3. Find on what days the sun is in these points of the ecliptic: for on those days he is vertical to the given place.

To find those places in the torrid zone to which the sun is vertical on a given day. Bring the sun's place in the ecliptic to the meridian; then turning the globe round, note all the places which pass through that point of the meridian: those are the places required.

After the same manner may be found what people are ASCIT for any given day.

The day and hour at any place being given, to find where the sun is vertical at that hour. Bring the sun's place to the meridian, and the degree over it is the sun's declination at that time; then bring the given place to the meridian, and set the index to the given hour; turn the globe till the index points to twelve at noon, and the place on the globe which lies under the degree of the sun's declination has the sun then vertical.

A place being given in the frigid zone, to find the time when the sun begins to appear above the horizon, and when it begins to disappear; and also the length of the longest day or night in that place. Rectify for the latitude; bring the ascending part of the ecliptic, i. e. for latitudes north of the tropic of Cancer the semi-circle intercepted between Capricorn and Cancer, to the fourth point of the horizon; observe the degree of the ecliptic which cuts that point, and find when the sun enters that degree, and this will give the time when the sun begins to appear in that latitude. Bring the descending part of the ecliptic to the same point of the horizon, and the calendar will shew when the sun leaves that latitude and disappears. Again, bring the ascending part of the ecliptic to the north point of the horizon, and the degree, as before, will shew in the calendar when the longest day begins; and by bringing the descending part of the ecliptic to the same north point, we shall find, in the same manner, when the longest day ends.

To find the latitude of the places wherein any given day is of any given length. 1. Bring the sun's place for the given day to the ecliptic, and set the index to the hour of twelve. 2. Turn the globe, till the index point at the hour of rising or setting. 3. Raise and depress the pole till the sun's place appear in the eastern and western sides of the horizon: then will the pole be duly elevated, and, consequently, the latitude given.

To find the latitude of those places in the frigid zone where the sun does not set for a given number of days. 1. Count so many degrees from the next tropic, towards the equinoctial point as there are units in half the number of the given days; because the sun, in its proper motion, goes nearly a degree every day. 2. Bring the point of the ecliptic, thus found, to the meridian; and its distance from the pole will be equal to the elevation of the pole, or latitude of the places required.

Any hour of the day or night being given, to shew all those places to which the sun rises and sets, where it is noon or midnight, and where day or night. 1. Find what place the sun is at that time vertical to, as already taught. 2. Let this place be brought to the zenith of the wooden

horizon; i. e. elevate the pole as the latitude of that place requires: then will the places on the eastern side of the horizon bethole the sun is setting to; and on the western side, those he rises to: those under the upper semi-circle of the meridian have it noon; and those under the lower, midnight. Lastly, to those of the upper hemisphere it is day; and to those in the lower, night.

Hence, as in the middle of an eclipse, the moon is in that degree of the ecliptic opposite to the sun's place; by the present problem it may be shown what places of the earth then see the middle of the eclipse and what the beginning or ending.

To find what places of the earth a planet, e. gr. the moon, is vertical to any day of the year. 1. Mark the planet's place on the globe, as above taught. 2. Bring this place to the meridian, and note the degree over it. 3. Turn the globe round, and the places which pass under the point are those required.

The declination of a star, or any other phenomenon, given, to find what parts of the earth the same is vertical to. Count as many degrees in the meridian, from the equator towards one pole, as are equal to the given declination; viz. towards the north, if the declination be to the northward; and towards the south, if the declination be south. Then turning it round, the places that pass through the extremity of this arch in the meridian are the places required.

To determine the place of the earth where any star, or other celestial phenomenon, will be vertical at a given hour. 1. Elevate the pole according to the latitude of the place, from whose noon or midnight the hours are numbered. 2. Bring the sun's place for that day to the meridian, and set the index at twelve o'clock. 3. Determine the place of the star on the surface of the globe, and bring it to the meridian; the index will show the difference of time between the impulse of the sun and star to the meridian of the place: note the point of the meridian over the place of the star. 4. Find in what places of the earth it is then noon, and set the index to twelve o'clock. 5. Turn the globe towards the west, till the index have passed over the interval of time between the culmination of the sun and star. Then, under the point of the meridian, before observed, will the place required be found. And hence may always be found what place a star, or other phenomenon, rises or sets at any given time.

To place the globe in such manner, under any given latitude, as that the sun shall illuminate all those regions which he actually illumines on earth. 1. Rectify the globe, i. e. elevate the pole according to the latitude of the place; bring the place to the meridian, and set the globe north and south by the compasses; thus, the globe having the same situation with regard to the sun as the earth has, that part thereof will be illuminated which is illuminated on earth. Hence also the globe being situate in the same manner, when the moon shines, it will show what parts are then illuminated by the moon.

And in the like manner, we may find when the sun and moon rise and set at any given time.

To find the distance of two places on the globe. Take the given places in the compasses, and apply them to the equator; the degrees which there subvert being reduced into miles, leagues, or the like, give the distances required.

The same may be done, and that more commodiously, by laying the graduated edge of the quadrant of altitude over the two places, and noting the degree intercepted.

To find how any one place bears from another. Bring one place to the meridian, and lay the quadrant of altitude over the other, and it will show on the horizon the point of the compass on which the latter bears from the former.

To find the proportion which the land bears to the sea. For this purpose Dr. Long proposes to take the papers of a large terrestrial globe, and after separating the land from the sea with a run of scissors, to weigh them carefully in scales. This method supposes the globe to be exactly delineated, and all the papers of equal thickness. By an experiment on the papers of Mr. Seneca's seventeen inch globe, he found that those comprehending the sea weighed 349 grains, and the others only 22; whence he inferred, that almost three fourths parts of the surface of our earth between the polar circles are covered with water, and that little more than one fourth is dry land. Dr. Long omitted weighing the papers within the polar circles, because the proposition which the land bears to the sea within them is not ascertained. *Long's Astron.* vol. I. p. 168. See *Magnitude of the Earth*.

GLOBE, to construct a dial by the. See *DIAL*.

The celestial globe has been improved by Mr. Ferguson: in this globe (see *Tab. III. Astronomy*, fig. 76) an arch MKH, of 23 $\frac{1}{2}$ °, is fixed on the north pole of the axis,

Vol. II. N° 154.

above the hour circle; and at the end is fixed an upright pin HG, standing directly over the north pole of the ecliptic, and perpendicular to that part of the surface of the globe. On this pin are two moveable coils at D and H, to which are annexed the quadrantal wires N and O, carrying two little balls representing the sun and moon. The coil at D is fixed to the circular plate F, on which are engraven the 29 $\frac{1}{2}$ days of the moon's age, beginning under the wire N, which wire, as it turns round, carries with it the plate F. These wires are fixed or slackened by the screw G, and the two little balls are made to rise and set at the same time and on the same point of the horizon, for the day to which they are rectified, as the sun and moon do in the heavens. The ball representing the moon may be forced as many degrees to either side of the ecliptic, as her latitude amounts to at any given time; and for this purpose, S is a small piece of pasteboard, the curved edge of which at S is to be set upon the globe at right angles to the ecliptic, and the dark line over S to stand upright upon it: from this line, on the convex edge, are drawn the 5 $\frac{1}{2}$ degrees of the moon's latitude on both sides of the ecliptic; and when this piece is set upright on the globe, its graduated edge reaches to the moon on the wire O, by which means she is easily adjusted to her latitude found by an ephemeris. The horizon of this globe is supported by two semi-circular arches, because pillars would stop the progress of the balls, when they go below the horizon in an oblique sphere. This globe is rectified by elevating the pole to the latitude of the place, bringing the sun's place in the ecliptic for the given day to the brazen meridian, and setting the hour-index to twelve at noon; then, setting the sun directly over his place in the meridian, and the moon over her place in the ecliptic, by fixing her wire under the number that expresses her age for that day on the plate F; and, lastly, laying the curved edge of the pasteboard S over the ecliptic below the moon, and adjusting the moon to her latitude over the graduated edge of the pasteboard. Harington rectified the globe, turn it round, and observe on what point of the horizon the sun and moon balls rise and set; for these agree with the points of the compass on which the sun and moon rise and set in the heavens on the given day; and the hour-index shows the times of their rising and setting, and also the time of the moon's passing over the meridian. This globe is also contrived for exhibiting the phenomena of the harvest-moon, see *Phil. Trans.* N° 483, art. 21. in vol. XLV. p. 535, or *Ferguson's Astron.* p. 291.

GLOBE, dialling. See *DIALLING*.

GLOBES, portable, are those with the improvements of Mr. Neale, for which he obtained his majesty's letters patent; by means of which he solves several astronomical problems, which do not admit of solution by the common globe.

GLOBE, planetary, is a machine, contrived and described by Mr. Ferguson; in which T (see *Tab. III. Astronomy*, fig. 77) is a terrestrial globe fixed on its axis standing upright on the pedestal CDE, on which is an hour circle, having its index fixed on the axis, which turns somewhat tightly in the pedestal, so that the globe may not be liable to shake; to prevent which, the pedestal is about two inches thick, and the axis goes quite through it, bearing on a shoulder. The globe is hung in a graduated brazen meridian, much in the usual way; and the thin plate N, NE, E, is a moveable horizon graduated round the outer edge, for showing the bearings and amplitudes of the sun, moon, and planets. The brazen meridian is grooved round the outer edge; and in this groove is a slender semi-circle of brass, the ends of which are fixed to the horizon in its north and south points; this semi-circle slides in the groove as the horizon is moved in rectifying it for different latitudes. To the middle of the semi-circle is fixed a pin, which always keeps in the zenith of the horizon, and on this pin the quadrant of altitude turns; the lower end of which, in all positions, touches the horizon at it and is moved round the same. This quadrant is divided into 90 degrees from the horizon to the zenith pin on which it is turned, at 90°. The great flat circle or plate AB is the ecliptic, on the outer edge of which the signs and degrees are laid down; and every fifth degree is drawn through the rest of the surface of this plate towards its centre. On this plate are seven grooves, to which seven little balls are adjusted by sliding wires, so that they are easily moved in the grooves, without danger of falling out of them. The ball next the terrestrial globe is the Moon, the next without it is Mercury, the next Venus, the next the Sun, then Mars, then Jupiter, and lastly Saturn; and in order to know them, they are separately stamped with the following characters: ☿, ♀, ♀, ☿, ♀, ♀, ♀. This plate or ecliptic is supported by four strong wires, having their lower ends

fixed into the pedestal at C, D, and E, the fourth being hid by the globe. The ecliptic is inclined 23½ degrees to the pedestal, and is therefore properly inclined to the axis of the globe which stands upright on the pedestal.

To rectify this machine. Set the Sun, and all the planetary balls, to their geocentric places in the ecliptic for any given time, by an ephemeris; then set the north point of the horizon to the latitude of your place on the brazen meridian, and the quadrant of altitude to the fourth point of the horizon; which done, turn the globe with its furniture till the quadrant of altitude comes right against the Sun, viz. to his place in the ecliptic; and keeping it there, set the hour-index to the XII. next the letter C.

By this machine the following problems, as well as many others, may be resolved.

To find the amplitude, meridian altitudes, and times of rising, culminating, and setting of the sun, moon, and planets. Turn the globe round eastward, or according to the order of the signs; and as the eastern edge of the horizon comes right against the sun, moon, or any planet, the hour-index will shew the time of its rising: and the inner edge of the ecliptic will cut its rising amplitude in the horizon. Turn on, and as the quadrant of altitude comes right against the sun, moon, or planets, the ecliptic cuts the meridian altitudes in the quadrant, and the hour-index shews the times of their coming to the meridian. Continue turning, and as the western edge of the horizon comes right against the sun, moon, or planets, their setting amplitudes are cut in the horizon by the ecliptic; and the times of their setting are shewn by the index on the hour-circle.

To find the altitude and azimuth of the sun, moon, and planets, at any time of their being above the horizon. Turn the globe till the index comes to the given time in the hour-circle; and keep the globe steady, and moving the quadrant of altitude to each planet respectively, the edge of the ecliptic will cut the planet's mean altitude on the quadrant, and the quadrant will cut the planet's azimuth, or point of bearing on the horizon.

The sun's altitude being given at any time either before or after noon, to find the hour of the day, and the variation of the compass, in any known latitude. With one hand hold the edge of the quadrant right against the sun; and, with the other hand, turn the globe westward, if it be in the forenoon, or eastward if it be in the afternoon, until the sun's place at the inner edge of the ecliptic cuts the quadrant in the sun's observed altitude; and then the hour-index will point out the time of the day, and the quadrant will cut the true azimuth, or bearing of the sun for that time: the difference between which, and the bearing shewn by the azimuth compass, shews the variation of the compass in that place of the earth. Ferguson's Astron. p. 297, &c.

GLOBE *amorphous*. See COMPREHENSIVE.

GLOBE *animalcula*, in Natural History, is a singular, minute, aquatic animal, whose form seems exactly globular, without either head, tail, or fins. It moves in all directions, either rolling like a bowl, or gliding along smoothly without turning itself at all. Its whole body is transparent, except where it is covered with circular black spots; some of which have six or seven, some one, two, three, four, or five, and others none at all. These spots are probably the eggs or young ones of the animal. The general appearance of the body exhibited a kind of short moveable hairs or bristles, by means of which it is conjectured the motions of the animal may be performed. Baker's Microsc. p. 322, &c.

GLOBE *crum-fur*, a ramulus. See HELLBORE.

GLOBE *daily*. See DAILY.

GLOBE *fish*, a name by which some species of the ostracion are called. See OSTRACION.

GLOBE *fluvial*, *fluvianthus*, in Botany, a genus of the *symplocos* *pitagoria* *symplocos* class; the characters of which are these: the flowers are composed of hermaphrodite florets and female half-florets, included in one scaly empaleme; the hermaphrodite florets are placed in the centre; they are funnel-shaped, and cut into five parts at the brim, with five short hair-like filamina, terminated by cylindrical fummitis and a germen, which decay, supporting a thick longer style having a single stigma; these are barren: the female half-florets are situated round the border, and have scarce any petals, but an oblong germen, supporting a bristly style, crowned by a double stigma; these have one oblong naked seed. Linnaeus enumerates three species, and Miller only two, which are annual plants, that must be kept in a hot-bed, and, in a cold summer, under a glass case, in order to ripen their seeds in our climate.

GLOBE *thistle*. See GLOBE THISTLE.

GLOBULAR *chart*, a representation of the surface, or some part of the surface, of the terraqueous globe upon

a plane; wherein the parallels of latitude are circles nearly concentric; the meridians, curves bending towards the poles; and the rhumb-lines also curves.

The merits of this chart consist in this, that the distances between places on the same rhumb are all measured by the same scale of equal parts; and the distance of any two places in the arch of a great circle, is nearly represented in this chart by a straight line. Hence land maps, made according to this projection, would indisputably have great advantages above those made any other way. See MAP.

But for sea charts, and the use of navigation, it is yet controverted, whether the globular chart be preferable to Mercator's, where the meridians, parallels, and particularly the rhumb-lines, are all straight lines; inasmuch as straight lines are found more easy to draw and manage than curves, especially such as rhumb-lines on the globular chart are. This projection is not new, though not much taken notice of till of late. It is mentioned by Ptolemy, in his Geography; as also by Blundeville, in his Exercises. See CHART.

GLOBULAR *sailing*. See GREAT-CIRCLE SAILING.

GLOBULARIA, in Botany. See BLUE DAILY.

GLOBULE, GLOBULUS, a little GLOBE; otherwise called a spherule.

Thus the red particles of the blood are called globules of the blood, on account of their redness and smallness. The Cartesian call the particles broken off the matter of the first element, globules of the second element. See CARTESIAN, &c.

GLOBULUS *naso*, is used for the lower, flexible, cartilaginous part of the nose.

GLOKEN *specie*, in Mineralogy, a term used by the Germans to express a sort of impure regulus of bismuth, obtained by accident, sometimes in the making of smalt. The bismuth ores are often so intimately mixed with the cobalt, that they cannot be separated from them. In this case, the arsenic being raised in the flowers, there remains at the bottom, instead of the fired vitrifiable earth of the cobalt, a sort of impure regulus of a reddish colour. This is bismuth, with an admixture of the earth of cobalt, and other extraneous matter. They sometimes call this whole matter by the common name of *specie*, but more usually they separate it into two parts, and call the under part, which is most solid, *gloken-specie*, and the upper part they distinguish by the name of *an caldarium*.

GLOMERELLS, in our old Writers, commissaries appointed to determine differences between scholars of a school or university, and the townsmen of a place. In the edict of the bishop of Ely, anno 1276, there is mention of the matter of the *glomerelli*.

GLORIA *Patri*, in the Liturgy, a formula of words repeated at the end of each Psalm, and on other occasions, to give glory to the Trinity; called also the DOXOLOGY. It is thus denominated, because beginning in the Latin office with these words, *Gloria Patri*, q. d. *Gloria be to the Father*, &c.

Pope Damasus is commonly said to have first ordered the rehearsal, or rather singing the Gloria Patri at the end of Psalms. Baronius, indeed, will have it to have been used in the times of the apostles; but its use, then, he allows to have been more obscure, and that it did not become popular till after the rise of Arianism, when it was made a kind of symbol of orthodoxy.

The fifth canon of the council of Vaison, held in 529, decrees, "that the name of the pope shall always be rehearsed in the churches of France, and after the *Gloria Patri* shall be added *sicut est in principio*, as it is done at Rome, in Africa, &c. on account of the heretics, who say, that the Son of God had his beginning in time." Fleury.

GLORIA *in excelsis* is also a kind of hymn rehearsed in divine service, beginning with the words *Gloria in excelsis Deo*, *q. d. in terra pax hominibus*, &c. *Gloria be to God on high, on earth peace*, &c.

GLORIOSA, in Botany. See SUPERB LILY.

GLOSS, GLOSSA, a comment on the text of any author, to explain his sense more fully and at large, whether in the same language, or in any other. See COMMENTARY.

The word, according to some, comes from *glossa*, tongue; the office of a gloss being to explain the text, as that of the tongue is to discover the mind. Others derive it from the Latin *glos*, of *glossa*, a filter-in-law, which, among lawyers, sometimes stands for filter; the gloss being, as it were, filter to the text.

Nic. de Lyra composed a *posill* or *gloss* on the Bible, in six volumes folio. The French say, proverbially of an ill comment, that it is *gloss d'Orléans*, *plus obscure que le texte*.

GLOSS is also used for a literal translation, or an interpretation

tation of an author in another language, word for word. Young scholars need an interlinear *gloss* for the understanding of Juvenal, Horace, Sallust, Persius, &c.

GLOSS is also used in matters of Commerce, &c. for the luster of silk, stuff, or the like.

GLOSSARY, GLOSSARIUM, a kind of dictionary for explaining the obscure, ancient, and barbarous words and phrases of an altered, corrupted, or refined language.

Spelman's *Glossary*, intitled *Archæologicum*, is an excellent work; though that author did not begin to study in this way till fifty years of age. M. Du-Cange's Latin *Glossary* in three volumes, and his Greek *Glossary* in two volumes folio, are excellent performances, full of uncommon erudition. Lindenbroek has a *Glossary* on the laws of Churlenage, &c.

GLOSSOCATOCHOS, a word used by some writers to express a surgical instrument, used to depress the tongue for examining the mouth. See **GLOSSOPATHA**.

GLOSSOCOMON, a surgeon's instrument, anciently used in setting broken and dislocated thighs and legs; as also in extending those which remained too short after setting.

The word is formed of *glossa*, tongue, and *comon*, to take care; and was properly and primarily given by the ancients to a little box, wherein they kept the reeds of their harpichord, &c.

The *glossocomon* is described as consisting of a hollow trunk, wherein the thigh or leg is laid; at the bottom hereof is a kind of wheel; and towards the top are two pulleys on each side. Several thongs of leather are tied both above and below the fractured place: those below are fastened to the axis of the wheel, which they are near; those above go over the pulleys to come to the axis, which they are likewise fastened to: so that the same turning of the wheel both draws the part of the leg or thigh, which is above the fracture, upwards; and that below, downwards.

GLOSSOCOMON, in *Mechanics*, is a name given by Hiero, to a machine composed of divers dented wheels, with pinions serving to raise huge burdens.

GLOSSOGRAFHE, in *Burgery*, a name used by some authors for the *lanterna*, or common TUMORY.

GLOSSOIDES, in *Natural History*, a name given by some authors to a species of stone, resembling the figure of the human tongue. This is a mere accidental configuration of a common flint or pebble, perfectly indeterminate in size and colour, and owing its form to no animal mould, as the stones found in shells usually do, but is a mere *infusa natura* in the concretion of the stone.

GLOSSOPETRA, or **GLOTOPETRA**, in *Natural History*, a kind of extraneous fossil, somewhat in form of a serpent's tongue; frequently found in the island of Malta, and divers other parts. See *Tak. Fossils*, class. 8.

Naturalists have been much divided as to the nature and origin of these bodies. Steno, De Corpore solido intra solidum Contento; Ol. Wormius, Differt. de *Glossopetra*; and Reysschius, De *Glossopetra* Lünebergenisibus, treat of them at large.

The vulgar notion is, that they are the tongues of serpents petrified; and hence their name, which is a compound of *glossa*, tongue, and *petra*, stone. Hence, also, their traditional virtue in curing the bites of serpents.

The general opinion of naturalists is, that they are the teeth of fishes, left at land by the waters of the deluge, and since petrified.

They even specify the very kind of fish, and take it to be that which Theophrastus and the Greek writers call *εὐχρηστος*, and the moderns the *shark*, or *sea-dog*.

Camerarius cannot persuade himself that the *glossopetra*, found in England, Malta, and round Montpellier, were ever the teeth of a sea-dog, or any other fish. The chief difficulty, he suggests, is the small quantity of volatile salt and oil which they afford by distillation. To which Dr. Woodward answers, in defence of the common system, that having lain so long buried under ground, it is no wonder they should have lost the best part of their volatile principles. It is certain, that human bones and skulls, long interred, do not afford near the quantity of those principles: that they would have done immediately after the person's death.

Another scruple, proposed by Camerarius, is, that the *glossopetra*, when exposed to the naked fire, turn to a coal, and not to a calx; contrary to what is asserted by Fabius Columna. Dr. Woodward answers, that it is likely enough the *glossopetra*, in burning, may assume the form of a coal, before it arrive to that of a calx.

The several kinds of the teeth of the same species, and those of the several different species of sharks, afford a vast variety of these fossil substances. Their usual colours are black, bluish, whitish, yellowish, or brown; and in shape, they usually approach to a triangular figure. Some of them are simple; others are triplicate, having a small point on each side of the large one: many

of them are quite straight, but they are frequently found crooked, and bent in all directions: many of them are serrated on their edges, and others have them plain: some are undulated on their edges, and slightly serrated on these undulations. They differ also in size as much as in figure; the larger being four or five inches long, and the smaller of less than a quarter of an inch.

They are most usually found with us in the strata of blue clay, though sometimes, also in other strata, and are frequent in the clay-pits of Richmond and other places. They are very frequent also in Germany, but no where so plentiful as in the island of Malta.

The Germans attribute many virtues to these fossil teeth; they call them cordials, sudorifics, and alexipharmics; and the people of Malta, where they are extremely plentiful, hang them about their children's necks to promote dentition. They may possibly be of as much service this way as an anodyne necklace; and if suspended in such a manner, that the child can get them to its mouth, may, by their hardness and smoothness, be of the same use as a piece of coral. See *SEMPER'S Tongue*.

GLOSSO-PHARYNGEAL, in *Anatomy*, are fibres which run along the lateral edges of the tongue, from which they are parted backward, and run down on the sides of the pharynx under the *Stylo-pharyngei*.

GLOSSO-STAPHYLINI, in *Anatomy*, are two small muscles fixed each in the lower and lateral part of the base of the tongue, from whence they run up obliquely backward along the anterior half arches of the septum palati, and terminate insensibly on each side near the uvula.

Mito-Glossat and *Stylo-Glossat*. See *MYLO-gloss* and *STYLO-gloss*.

GLOSSOPATHA, in *Surgery*, an instrument, called by some *speculum lingue*, and used to depress the tongue, in order to look into the fauces.

There are many inflammatory disorders of the mouth, fauces, and palate, which require a depression of the tongue, while they are inspected and treated with proper remedies. The handle of a silver spoon is made to supply the place of this instrument in most cases, and answers the purpose very well. Whichever is used, care should be taken to depress very gently, to avoid giving the patient pain, as also to avoid irritating the mouth and inflamed parts.

When injections are to be made into the mouth, this instrument or the spoon should also be applied, and the syringe should be conveyed into the mouth over it.

GLOTTIS, in *Anatomy, a cleft or chink in the larynx, serving for the formation of the voice.*

The *glottis* is in form of a little tongue, whence its name, from *glossa*, tongue. For the same reason, the Latins call it *lingula*, i. e. *little tongue*. Through this chink the air descends and ascends in respiring, speaking, singing, &c. It has an apparatus of muscles, whereby we contract and enlarge it; and hence all the variety of tones in the voice.

The *glottis* is covered and defended with a thin, soft cartilage, called the *epiglottis*.

GLOTTIS, in *Ornithology*, a name given by many authors to a bird of the long-legged kind, approaching to the nature of our red shank, but larger and longer legged, and generally known by the name *limosa*.

GLOVE, *chirotheca*, a habit or covering for the hand and wrist, used both for warmth, decency, and as a shelter from the weather.

Gloves are distinguished, with respect to commerce, into leather *gloves*, silk *gloves*, thread *gloves*, cotton *gloves*, worsted *gloves*, &c.

There are also *gloves* of velvet, satin, taffety, &c. Leather *gloves* are made of shamoy, kid, lamb, doe, elk, buff, &c. There are, also, perfumed *gloves*; washed, glazed, waxed *gloves*; and white, black, fust-colour, &c. *gloves*; single, lined, topped, laced, fringed with gold, silver, silk, fur, &c.

It is a proverb, for a *glove* to be good and well made, three kingdoms must contribute to it; Spain to dress the leather, France to cut it, and England to sew it. But, of late, the French seem to have appropriated the functions of the other two; the *gloves* of the French manufacture being now said to have the advantage, in point of dressing and sewing, as much as of cutting.

To throw the *GLOVE* was a practice or ceremony very usual among our fore-fathers, being the challenge whereby another was defied to single combat. It is still retained at the coronation of our king, when the king's champion casts his *glove* in Westminster-hall.

Feyn supposes the custom to have arose from the eastern nations, who in all their sales and deliveries of lands, goods, &c. used to give the purchaser their *glove* by way of livery or investiture. To this effect he quotes Ruth iv. 7. where the Chaldean paraphrase calls *glove* what the common

common version renders by *gloss*. He adds, that the rabbins interpret by *gloss*, that passage in the Mishna, *In laqueo extendam calcamentum meum, Quia Edon will I cast out my gloss*. Accordingly, among us, he who took up the *gloss*, declared thereby his acceptance of the challenge; and as part of the ceremony, continues Favin, took the *gloss* off his own right-hand, and cast it upon the ground, to be taken up by the challenger. This had the force of a mutual engagement on each side to meet at the time and place which should be appointed by the king, parliament, or judges.

The same author asserts, that the custom which still obtains of blessing *gloss*, in the coronation of the kings of France, is a remnant of the eastern practice of giving possession with the *gloss*. Lib. xvi. p. 1017, &c.

The delivery of a *gloss* was in frequent use formerly, as a symbol of investiture. See Du-Cange, Gloss. Lat.

Gloss was also used to signify the steward's or bailiff's fee, or part of the price of the investiture or purchase-money of the land. *Si aliquam terrarum portionem omnium integritatis, domus venditionis habebantur, scilicet, ut dicitur, quasi venditor inde habuerit solutis. Major pars terra illius pro warris accipitur quasi dicitur.* Where warris signifies *gloss*, or, in French, *gens*.

Hence the common custom, in many bargains, of giving servants money for a pair of *glosses*.

Anciently it was prohibited the judges to wear *glosses* on the bench; and at present, in the stables of most princes, it is not safe going in without pulling off the *glosses*.

GLOUTRUS, in *Anatomy*, a name given by Riola, and some others, to the muscles of the thigh, generally called *glutaei*, or simply *glutaei majores*, &c.

GLOW-WORM, *lucifera*, in *Zoology*, a genus of insects of the *glutatorum* order; the antennae of which are octacarpous, the jaws prominent and denticulated, the eyes in a small degree prominent, the thorax of a roundish margined figure.

Cantharis and *cicindela* have been often used, indiscriminately, for the *glutatorum*; but they form two distinct genera of the same order, comprehending several species, in the Linnæan system. The species of the *cantharis* have scutigerous antennae; the thorax is margined and shorter than the head, the exterior wings are flexible, and the sides of the abdomen are plicated and papillose. In most species the thorax is flattened, but in some roundish. Of this genus Linnæus reckons twenty-six species. See *CANTHARIDES*. Of the *cicindela* he enumerates fourteen species, distinguished by their colour and the spots on their exterior wings: thus, the field or green *glutatorum* hath five white spots on these wings; the black *glutatorum*, that frequents woody places, two; the brassy *glutatorum*, common in moist places, has broad excavated spots on the wings; the black *glutatorum*, with a round thorax, common in rocky places, has two ferruginous spots, &c.

The male and female differ greatly in this species of insect. The male has wings, and is a small fly; the female has no wings, but is a large crawling worm.

The body of the male is oblong, and somewhat flattened; the wings are shorter than the body; the head is broad, don, and flat; the eyes are large and black. This has no light issuing from it, and is not commonly supposed to bear all of kin to the *glutatorum*.

The female is what we expressly call by this name: this is a very slow-paced animal, without wings, and somewhat resembling a caterpillar; the head is small, flat, hard, and black, and sharp towards the mouth; it has short antennae, and six moderately long legs; the body is flat, and is composed of twelve rings, whereas the body of the male consists only of five; it is of a dusky colour, with a streak of white down the back. It is often seen in the day-time, but is not known except in the dark: at which time it is easily distinguished by the glowing light, or luminescent flame, that is seen near the tail, issuing from the under part of the body.

The common *glutatorum* is frequently met with under our hedges, and, if carefully taken up, may be kept alive many days on fresh turfs of grass; all which time it will continue to shine in the dark.

The light of this little insect is so strong, that it will show itself through several substances, in which the creature may be put up; a thin pill-box easily shews it through, and even though lined with paper, the light is not impeded in its passage by both. The creature is sluggish, and appears dead in the day time, and its light is not distinguishable, even if carried into a darkened room, unless the creature be turned upon its back, and disturbed, so as to be put in motion, and then it is but very faint: after long-let the light begins to return, and with it the life and motion of the animal. The motion and light of this creature seem, in some measure, to depend upon one another: it never shines but when its body is in

some sort of motion; and when it shines most, the body is extended to one third more than its length in the day-time. In the time of brightest shining, it will sometimes on a sudden turn its body about, and the light will not be larger than the head of a pin; and, on being touched, the will then immediately extend herself, and the light will become as large and bright as ever. Phil. Trans. N° 71. The whole insect is used in medicine, and recommended by some against the stone. Cardan ascribes an anodyne virtue to it.

GLOW-WORM, *fly*, *cicindela volans*. In the warmer months of the year, this creature is sometimes caught in our houses flying to the flame of a candle, and when examined in the dark, it is found luminous at these times, though perhaps less, or not at all so, at others; which may be a reason of its not being known, though caught in the fields: and to this it may be owing, that many who have described it have thought it not a native of England. See *Tab. of Microscopical Objects*, *tab. 1*.

Without wings it is frequently enough found in form of the common *glutatorum*, and then always shines. Aldrovand has very well described the *cicindela volans*, and says, that it lays eggs which hatch into small worms, and that these after a time become flies, by the same sort of change which happens to caterpillars and other reptiles which become butterflies, and other species of winged insects. Mousset, and Thomas Bartholin, both describe the animal much as Aldrovand has done; but they allow only the male to have wings; but Julius Scaliger contradicts this, and says, that he has caught them both winged in the act of generation: this is a plain proof that both sexes are winged; yet it has not happened that both sexes have been acknowledged to be so, even by those who have quoted this passage. And Mr. Walter, who gives an account of them in the Philosophical Transactions, observed them in the same manner in the act of copulation both winged, and with no other difference between them but that the female was the larger of the two, which is the case in regard to many insects. Julius Scaliger. Exerc. 191. Phil. Trans. N° 167. p. 841.

The male and female in this winged state both shine in hot weather, and their light is so vivid as to be easily seen even while there is a candle in the room; and the vibrations of it are irregular, and its colour greenish. The luminous parts are two small specks under the tail at the end, and the light continues in these some time after the tail is cut off, but then gradually goes out.

The parts of insects continue alive in some degree for a considerable time after they are cut off, and probably the light in the tail of this animal continues just as long as that sort of life remains in it. Mousset, cap. 15.

The use of this light seems to be to direct the animal in its course, and in the taking of its prey, and to this purpose it is admirably placed. The tail is easily bent under the belly, and then throws the light full upon any object about, or under the head of the animal, and the eyes are placed not on the upper part, but on the under side of the head: so that they have all the advantages of it, while the light in this part is not offensive to the eyes, as it naturally would have been if carried before the head. The creature can, upon occasion, cover this light so as not to be known, or purged by it, by its enemies. Thomas Bartholin. De Lucæ Anim. lib. ii. cap. 12.

This insect is of the beetle kind, of a brown and dusky colour. It has hard case or shell wings, as the other beetles have, and when these are expanded, there appear a pair of very large membranous ones; its head is covered with a sort of shield or broad-brimmed hat: under this hat are placed the eyes, which are black and large, and are movable; so that the creature can, upon occasion, thrust them forward: it has two hairy antennae, and its legs are like those of the common fly, hard, thick, and hairy. Its eyes afford an easy object for the microscope, being composed of an infinite number of lenses, as those of the fly and other insects. Aldrovand. De insect. lib. i. cap. 8.

GLUE, *Gutta*, a viscous, tenacious matter, serving as a cement to bind or connect divers things together.

There are divers kinds of *glue* made use of in the divers arts; as the common *glue*, *glue* *glor*, *parment* *glue*; but the two last are more properly called *size*.

The common or *strong* *GLUE* is a commodity used by innumerable kinds of artificers: as joiners, cabinet-makers, case-makers, haters, book-binders, &c. and the consumption thereof is very considerable. The best is that made in England, in square pieces, of a ruddy brown colour: Flanders *glue* is held the next after the English.

Glue is made of the skins of all kinds of beasts; as oxen, cows, calves, sheep, &c. The older the beast is, the better is the *glue* that is made of its hide. Indeed, it is rare they use whole skins for this purpose; those being capable

capable of being applied to better purposes; but they make use of the flavings, parings, or scraps thereof; and sometimes they make it of the feet, sinews, nerves, &c. of beasts.

That made of whole skins: the belly and that of sinews, &c. the worst; and hence, chiefly, arises the difference of *glue*, and the advantage of English and Flemish *glue*.

GLUE, method of making. To make *glue* of parings, they first steep them two or three days in water; then washing them well out, they boil them to the confidence of a thick jelly; this done, they pass the jelly, while yet hot, through other baskets; to separate from it any impurities; and, in order to purify it still farther, they let it rest some time. When the ordures, or foreign matters, are precipitated to the bottom of the vessel, they melt and boil it a second time.

This done, they pour it into flat frames, or moulds; whence it is taken out, when pretty hard and solid, and then cut into square pieces or cakes. Nothing new remains but to dry it in the wind, on a sort of coarse net, and afterwards to bring it to finish the drying.

The *glue* made of feet, sinews, &c. is managed after the same manner, with this only difference, that they bone and scour the feet, and do not lay them to sleep.

The best *glue* is that which is oldest: the surest test of its goodness is, to lay a piece to sleep three or four days in water; if it swell considerably without melting, and, when taken out, resume its former dryness, it is excellent.

GLUE, best. See Wax.

GLUE, fish, is a sort of *glue* made of the nervous and mucilaginous parts of a large fish, found chiefly in the Russian seas.

These parts being boiled, bear a near resemblance to that viscid matter found on the skins of cod-fish. When boiled to the confidence of a jelly, they spread it on a leaf of paper, and form it into cakes, in which state it is sent to us.

Fish-glue is of considerable use in medicine, and others of arts; where it is better known under the name of *isinglass* and *ichthyocola*.

A strong and fine *glue* may be prepared with isinglass and spirit of wine thus: steep the isinglass for twenty-four hours in spirit of wine or common brandy. When the menstruum has opened and mollified the isinglass, they will be gently boiled together, and kept stirring all the while, till it appears well mixed, and till a drop thereof, fasted to cool, presently turns to a strong jelly. Then dip it, while hot, through a clean linen cloth, into a vessel to be kept close stopped. A gentle heat suffices to dissolve this *glue* into a transparent and almost colourless fluid, very strong: so that pieces of wood, *glued* together with it, will separate elsewhere than in the joint joined. Boyle's *Works*, abridg. vol. I. p. 130.

A strong compound *glue* may be made by infusing a mixture of cream of tartre, in small pieces, with isinglass *glue*, in as much spirit of wine as will cover them, for about twenty-four hours; then melt the whole together, and add as much powdered chalk as will make it as opaque white.

A strong *glue*, but will resist moisture, may be obtained by dissolving gum sandarac and mastic, of each two ounces, in a pint of spirit of wine, and adding about an ounce of clear turpentine; then take equal parts of isinglass and parchment *glue*, and having pounded them into small pieces, put the solution of the gum upon them, and melt the mixture in a covered vessel, with a heat less than that boiling water; then strain the *glue* through a coarse hen cloth, and putting it again over the fire, add about an ounce of powdered glass.

Or, a strong *glue*, it will resist water, may be made by adding half a pound of common isinglass *glue* to two quarts of skimmed milk, and evaporating the mixture to a due confidence.

A *glue*, that will hold against fire and water, may be made by mixing a handkerchief quick lime with four ounces of linseed oil, boiling them to a good thickness, and spreading the mixture on 4 plates in the shade: it will thus become exceeding hot, but will easily be dissolved over a fire, and be fit for use. See **Cement**.

GLUME, gluma, among *Balanis*, a species of cup, consisting of two or three membranous valves, which are often pellicled at the edges. This kind of cup belongs to the grasses. See **Grass**.

GLUT, among *Falcores*, the slim substance that lies in a hawk's mouth.

GLUTEUS, in *Anatomy*, is a name common to three muscles, whose office is to extend the thigh. The first, *GLUTEUS major*, or the greater, arises semi-circularly from the os coccygis, the spine of the sacrum, the spine of the ilium, and a strong ligament which runs between the sacrum and tubercle of the ischium: and descending, is inserted into the linea aspera, four fingers breadth below the great trochanter. See *Tab. Anat. Edinb.* fig. 1. n. 51. fig. 6. n. 33.

GLUTEUS medius, or the middle one, called *minor*, or *minor*, arises from the spine of the ilium, under the former, and is inserted into the superior and external part of the great trochanter. See *Tab. Anat. Edinb.* fig. 4. n. 50. fig. 2. n. 33; fig. 6. n. 32. fig. 7. n. 23.

GLUTEUS minimus, or *minor*, arises from the lower part of the external side of the ilium, under the former, and is inserted at the superior part of the great trochanter. See *Tab. Anat. Edinb.* fig. 2. n. 31.

GLUTINATIVE, **AGGLUTINATIVE**, or **CONGLUTINATIVE**, in *Medicine* and *Pharmacy*. See **CONGLUTINATION** and **AGGLUTINATION**.

GLUTTA, a name given by some authors to the *guttae* or *guttulae* of *Cannabae*.

GLUTTON of *Buffon*, in *Zoology*, is the *URUS* *Infest* of *Linnaeus*, and mentioned by authors under the names of wolverene, carcajou, quick-latch, &c. Mr. Pennant has described this animal as a species of *BEAR*, with a black sharp-pointed visage; short rounded ears, almost hid in the hair; hairs on the head, back, and belly, reddish, with black tips; sides of a yellowish brown, which passes in the form of a band over the hind-part of the back, above the tail; a white spot on the throat; a white mark, like a crescent, on the breast; strong and short legs of a deep black; five toes on each foot, not deeply divided, though Mr. Edwards only observed four on the fore-feet of the animal which he describes; the bottom of the feet covered thickly with hair; claws strong and sharp, and white at their ends; tail clothed with long coarse hairs, those at the base reddish, and at the end black, some of which are six inches long. The length of this animal from the nose to the tail is twenty-eight inches. The whole body is covered with long and thick hair, which varies in colour according to the season. M. Buffon has described this animal (see *Tab. II. Quadrupeds*, N° 16.) as two feet two inches in length, from the tip of the nose to the root of the tail; the face, as far as the eye-brows, is black; the eyes are small and black; from the eye-brows to the ears the hair is black mixed with brown; the ears are short, or about an inch long; the hair under the lower jaw and between the fore-feet is spotted with white; the fore-legs are eleven inches long, and the hind legs twelve inches; the tail is eight inches, and the hair of the tail four inches; the four legs, the tail, and the back, and the lower part of the belly are black; from the shoulders to the root of the tail the hair is reddish; on the sides it is soft, thin, and white; the fore-feet, to the extremity of the claws, are 11 inches in length, and 2 1/2 inches in breadth; they are furnished with five hooked claws, the middle one being 1 1/2 inch long; the hind feet are 1 1/2 inches long, and 2 1/2 broad: the upper jaw has six cutting teeth, one on each side being somewhat thicker than the rest; two large teeth, seven lines long, a little bent, and five grinders, two of which are considerably larger than the others; in the lower jaw there are five grinders, one of which is very large; two large teeth that are a little bent, and six small ones: about the throat and under the eyes there is a little hair, which is about two inches in length.

This animal is found in the northern parts of Europe and Asia, and in Hudson's Bay, and Canada. It has been represented as a very voracious and cruel animal, whence its name *glutton*: it has been said, that it feeds to such a degree, as to be obliged to discharge its load by pressing between two trees; though M. Buffon apprehends that the relations of voyageurs have been exaggerated. It is very slow in its motion, and, therefore, takes its prey by surprise. In America it is called the *beaver-slayer*, because it devours those animals. It will often lurk on trees, and fall on quadrupeds that pass under it, and fasten to animals of a very large size, and will eat a hole in their bodies, or tear out their eyes. It is particularly eager after the fish or white fox. In its wild state it is very fierce, but capable of being tamed. It burrows under ground. The skin of the *glutton* is much valued in Siberia and Kamtschatka, and the fur is greatly esteemed in Europe: that of the north of Europe and Asia is much finer, and of a more glossy black than that of the American kind. See Pennant's *British Zoology*, p. 195; &c. Buffon's *Hist. Nat. tom. xxvii. p. 70. edit. 1766*, and Supplement, tom. vi. p. 67. &c. edit. 1777.

GLYCOPIROSS, in *Botany*, a name by which some authors have called the solanum lignosum, or *oleocoma*.

GLYCYCALAMUS, a word used singly as the name of a vegetable substance by some of the Greek writers; but by the most ancient it is only used as an epithet for a peculiar kind of lina. This word *glycyphorum* is a name given by Muretus and others to the *callis filula*; but by other of the ancients it seems to have been made the name of the sugar-cane.

GLYCINE, *Cavolina Kidney-bean tree*, or *Kushked-sted* *Liquorice Path*, in *Italy*, a genus of the *diadelphia decandria* class: the characters are, that the emblement of the flower is of one leaf, divided into two lips at the top, the upper lip being obtuse and indented, and the lower lip longer, trifid, and acute: the flower is of the butterfly kind; the standard is heart-shaped, deflexed on the sides, gibbous on the back, and indicated at the point: the wings are small, oblong, and oval towards their end, and bend backward: the keel is narrow, sickle-shaped, turning upward with its point to the standard, where it is broadest: it hath ten stamens, nine of which are joined in one body and the other stands single, terminated by single filaments; in the centre is situated an oblong germen, supporting a spiral cylindrical style, crowned by an ovate stigma: the germen afterward becomes an oblong pod with two cells, including kidney-shaped seeds. Miller enumerates five species, and Linnæus ten.

GLYCONIAN, **GLYCONIUS**, in the Greek and Latin poetry.

A *Glyconian verse* is that, consisting of two feet and a syllable; at least this is Scaliger's opinion: who adds, that the *Glyconian verse* was also called the *Euripidean verse*. See **VERSE**.

Others hold, that the *Glyconian verse* consisted of three feet, a spondee, and two dactyls; or rather a spondee, chorambus, and an iambus or a pyrrhus: which opinion is the most followed.

Sicce diti potius Cypris is a *Glyconian verse*.

GLYCERYLUM, in *Italy*, and *Medicine*, *Liquorice*. See **LICORICE**.

GLYPHE, or **GLYPHIS**, in *Sculpture* and *Architecture*, a general name for a cavity or canal, whether round, or terminating in an angle; used as an ornament in any part.

The Greek word is *γλυφω*, which literally signifies *graving, niching*.

Figura is properly a niche or indentation made in graving; or, more properly, it is the notch in the end of an arrow, in which the fleting goes.

GLYSTER. See **CLYSTER**.

GMELINEA, in *Botany*, a genus of the *didymia angiosperma* class: the calyx of which is quadridentate; the corolla campanulate and divided into four segments; two of the anthers are bipartite, and two simple; and the fruit is a drupe inclosed in a bilocular nut or kernel.

GNAPHALIUM. See **CUDWORT**.

GNAPHIUS, in *Ichthyology*, a name given by Athenæus and other of the Greek writers to the **TENCH**.

GNAT, *culex*, a genus of the order of *diptera*, or two-winged insects, whose mouth is furnished with bill-like fangs inclosed in a flexible sheath.

There is no species of insect that we have so much reason to dislike in regard to the injury it does us as the gnat. Others indeed give us more pain with their stings, but it is not by accident that we are struck by them; the gnat thirsts for our blood, and follows us about in whole companies for it. There are many marshy places where the legs and arms are all the summer swarmed to an enormous size by the repeated stings of these insects, and in many other countries they are much more troublesome than with us.

But as troublesome enemies as these little creatures are to us, there is that about them which is extremely worthy our admiration; nor can we indeed fall greatly to admire even the very instrument of the mischief they do. They have beside this many very observable particulars in the course of their lives.

All the naturalists of late years have applied the microscope to the examination of the parts of this little animal, and Swammerdam, Hook, Bonanni, Lewenhook, &c. have given very good accounts, and very valuable drawings of the creature.

There is a great number of very small species of gnats, and though some are considerably large, yet none even of these approaches to the size of the tipula, or rather long-legs, as commonly called. The larger tipulae are therefore easily distinguished from the gnats; but Swammerdam, Goudart, Lister, and others, have very often given as the smaller tipula among the species of gnats. Both have long slender bodies, and both prominent corelets, which make them look hump-backed; but when either of these insects is taken into the hand it is very easily known, the gnat having a very long trunk, and the tipula no trunk at all.

There is a prodigious number of species of the gnat kind, taking in the smaller ones; Dr. Derham observed near forty different species about Uppminster in Essex: but of those of a size to be remarked with ease, and without the help of glasses, there are three principal kinds: the one has its body variegated with white and black; this

is the larger kind, and its corelet is streaked with black or deep brown, and white lines or greyish-ones; these have brown eyes: another is smaller than this species, and has a plain brown body, the colour of the corelet, and that of the eyes is the same as in the larger or first species: the third kind is the smallest of the three and the most common, has its corelet reddish, or of a faded reddish yellow, and the body whitish, and on the under part of the belly every ring has one single brown spot: the rest is grey: the eyes of this species are of a very pleasant green.

All the gnats have a long cylindric body composed of eight rings: their corelet is short, but large, in proportion to the size of the fly, and to this are fixed the six legs, which are hairy, with six joints to each, and at the end two little claws, the wings, and the balancers; four figmæ are also found here, near the calf in other flies: the two first of these are placed near the head, and have been mistaken for ears.

The antennæ of gnats are extremely weak observation, and differ much from one another. Some of them are elegantly feathered; these belong to the males of certain species, for the antennæ of the females are not so beautiful. The bristly-horned or male gnat has two pair, one of which is surrounded, at small distances, with long hairs, issuing out circularly, each circle lessening as it approaches the extremity of the antennæ: the other pair are longer and much thicker, and hairy from end to end. In the great belled or female gnat, the first pair of antennæ, though of the same figure as the male's, has hairs not near so long, and the second pair is shorter than the first by at least three parts in four. Reaumur, Hist. Insect. vol. iv. p. 574, &c. Baker's Microsc. 1743, p. 203, &c. For the trunk and wings of the gnat, see **TRUNK** and **WINGS**.

GNAT, eggs of. See **EGGS**.

For the eggs of GRATE, see **EYES of FISH**.

GNAT-WORM, in *Natural History*, a small water-insect, produced of a gnat, and which is, after its several changes, transformed into a gnat again.

From the eggs, deposited by the gnat on the surface of the water, proceed a number of minute worms, which sinking to the bottom of the water, form for themselves coverings of fine sand or earth, cemented together with a sort of glue, but open at both ends, that they may come out and enter as occasion requires.

These worms do not frequent rivers; but ditches, ponds, and other standing waters, afford them in vast abundance, from the middle of May till toward the beginning of winter. This is the reason why watery and moist places are found most to abound with gnats, and why the wet summers are found to produce the greatest numbers of them; because in dry seasons, the ponds and ditches, where they are to pass their worm-life, are dried up, and the worms killed. These are creeps, however, that one need not go far to seek, since a sill of water, exposed in any open place in the summer months, will not fail to afford plenty of these worms a little time. Before these worms are arrived at their full growth, though they are then but small, the actually found, because they are under a necessity of coming frequently to the top of the water, by having a canal for frequent respiration; and to do this, they are obliged to keep the end of a small pipe they are furnished with, from the last ring of their body, above water. The end of this pipe is hollow and indented, and forms a sort of funnel on the surface of the water: it is of the length of about three rings of the body, and is somewhat thicker at its insertion than at its extremity.

As there is a vast number of species of gnats, there is no less of the worms from whence they are produced; and to this is in a great measure owing the variety in the figures given of the worms; the authors who have treated of them; which may be not a little added to by the particular views in which their draughts have been taken. Notwithstanding all the variations of these figures, the general form of the animal is however the same in all, and the species cannot but be known from any of them. While the worm is young, the body is whitish or greenish; but when it is at its full growth, and draws near the time of its changes, it becomes greyish. The great transparency of the body of this worm gives a fine view of what passes within it; it is at any time easy to see in the motion of the intestine, by which the food is pushed on towards the anus. The two principal tracheæ are also seen very distinctly in this creature: they are two white tubes placed in a parallel direction one to another, and run from the first ring to the tube of respiration.

The great worm several times changes its skin in the course of its life. After three changes of this kind, which usually happen in the space of three weeks, or thereabout,

thereabout, it undergoes a fourth, where the old skin is as easily thrown off as in the rest, but the animal now appears in a new form, that of a nymph: it is now shorter and rounder than before, and the body is so bent that the tail is applied to the under part of the head; this, however, is only its form in a voluntary state of rest; for it can yet move, and when it pleases extends its tail, and swims about as swiftly as when in its other state.

When the creatures have quitted their first habitations and the figure of worms, they ascend to the top of the water, inclosed in a kind of shell, with a large head and mouth, two black eyes, two horns, several tufts of hairs on different parts of the body, and a tail with a brush of hair at the end of it, which, being smeared over with an oily fluid, serves to keep them above water; their heads being sometimes lifted in the air, and sometimes plunged into the water, while the tail slides along the surface: and when the oil on the tail begins to dry, they shed from their mouth a fresh supply, which renders it capable of steering where they please, without being wetted and damaged by the water.

All the parts of the future *gryllus* may be seen in this nymph: the skin of it is extremely thin and transparent, yet sufficiently tough and firm for the life it is intended for. It is uncertain how long exactly the animal lives in this nymph state; but after the time is accomplished, its change into a *gryllus* is very quick, and is attended with great danger to the animal, since multitudes are drowned in the act of getting out and springing into the air. Besenar, Hist. Inf. vol. iv. Baker's Microf. 1743. p. 88.

GNETUM, in *Botany*, a genus of the *monocotyledon* class, with male and female flowers on the same plant, neither of which have any corolla; the antherum in both is fealy; the filament of the male is single, with double anthera; the style of the female is furnished with a trifid stigma: the fruit is a monospermous drupe.

GNIDIA, in *Botany*, a genus of the *classia monogynia* class; the calyx of which is infundibuliform, and divided into four segments; the flower consists of four petals, inserted into the calyx; the fruit is in the shape of a berry, containing a single seed.

GNOMES, **GNOMAT**, a name which the Chaldeans give to certain invisible people, whom they suppose to inhabit the inner parts of the earth, and to fill it to the centre. They are represented as very small of stature, tractable, and friendly to men; and are made the guardians of mines, quarries, hidden treasures, &c. Vigenere calls them *Gnomoni*: the females of this species are called *Gnomides*.

Vignoul de Marville, in his *Melange de Histoire & de Littérature*, tome i. p. 100. gives a relation of a conference with a philosopher of this class, who held, that an infinity of spirits inhabited each of the four elements, fire, air, water, and earth, under the denomination of *Salamanders*, *Sylphs*, *Ombres*, and *Gnomes*; that the *Gnomes* are employed in working or actuating the machines of brutes upon earth.

He added, that some philosophers of that sect held that these spirits were of two sexes, for the two sexes of brutes or moving machines; that they were more or less perfect as the brutes were; and that there was an infinite number of exceedingly small ones, to actuate the infinite number of insects and animals, both those that are visible and those which are too small to come under our senses; that all these spirits, in general, govern their respective machines according to the disposition of the parts or organs, the humours, temperaments, &c. that they do not lay hold of all machines indifferently, but of those suited to their own character, element, &c. that a naughty one, for instance, seizes a Spanish gonnat; a craft one a yger, &c.

GNOME, *Pyrausta or Glia*, is also used for a short, pithy, and intentioned observation, reflection, or the like, which is worthy to be treasured up and remembered.

Such is that of Juvenal, *Grandem esse, ut sit mens fons in corpore fons*. The writers of rhetoric distinguish several kinds of *gnomes*, according as they turn on words, on actions, or both; denominating them *verbal*, *active*, and *mixed gnomes or chreia*. See **APHORISM**.

GNOMON, in *Dialine*, is the style, pin, or cock of a dial, the shadow whereof pointeth out the hours. The word is Greek *gnomon*, which literally imports somewhat that makes a thing known; because the style or pin indicates or makes the hour, &c. known.

The *gnomon* of every dial is supposed to represent the axis of the world; and therefore the two ends or extremities thereof must directly answer to the north and south poles. See **DIAL** and **DIALING**.

GNOMON, in *Geometry*. If a parallelogram be divided into four lesser ones, by two lines intersecting each other,

and one of these parallelograms be retrenched or taken away, the other three will make a *gnomon*, ordinarily called a *gnomon*.

Or, a *gnomon*, in a parallelogram, may be said to be a figure formed of the two complements, together with either of the parallelograms about the diameter. Thus, in the parallelogram AC, Tab. II. *Geometry*, fig. 47, the *gnomon* is M + a + b + N; or M + N + X + Z.

GNOMON, in *Astronomy*, denotes an instrument or apparatus for measuring the meridian altitudes, and declinations of the sun and stars.

Those conversant in observations prefer the *gnomon*, by some called the *astronomical gnomon*, to the smaller quadrants, both as more accurate, easier made, and more easily applied.

Accordingly, both ancients and moderns have made use of *gnomons*, or upright pillars of a known height, erected on a level pavement, for making their more considerable observations.

The most ancient observation of this kind, extant, is that made by Pythacus, in the time of Alexander the Great, at Maritima, where he found the height of the *gnomon* was to the meridian shadow, at the summer solstice, as 213 to 600; just the time at Galesandus found it to be, by an observation made at the same place, almost two thousand years after, viz. in the year 1636. Riccioli, *Almag.* vol. i. lib. iii. cap. 14.

Uluogh Begh, king of Persia, &c. used a *gnomon* in the year 1477, which was one hundred and eighty Roman feet high; that erected by Ignazio Dante, in the church of St. Petrus, at Bologna, in the year 1526, was thirty-seven feet high: M. Callini erected another twenty feet high in the same church, in the year 1653.

The Egyptian *gnomons* were also used as *gnomons*; and we may add, that the Spaniards, in their conquest of Peru, found pillars of curious and costly workmanship set up in several places, by the meridian shadows of which their astronomers or philosophers had, by long experience and repeated observations, learned to determine the times of the equinoxes; which seasons of the year were celebrated with great festivity and rich offerings, in honour of the sun. Garcilasso de la Vega Hist. Peru. lib. ii. cap. 22. See **MARTIAN** *Ant.*

To erect an *astronomical gnomon*, and observe the meridian altitude of the sun by the same. Erect a perpendicular style, of a considerable height, on the meridian line; note the point where the shadow of the *gnomon* terminates when projected along the meridian line: measure the distance of that extreme from the *gnomon*, i. e. the length of the shadow: thus having the height of the *gnomon*, and the length of the shadow, the meridian altitude of the sun is easily found.

Suppose, e. gr. TS (Tab. Optics, fig. 13) the *gnomon*, and TV the length of the shadow. Here, in the right-angled triangle STV, having the two sides TV and TS, the angle V, which is the quantity of the sun's altitude, is found out by this analogy: as the length of the shadow TV: is to the altitude of the *gnomon* TS: so is the whole line or radius: to the tangent of the sun's altitude above the horizon.

The following example will serve to illustrate this proposition: Pliny tells us, Nat. Hist. lib. ii. cap. 72. that at Rome, at the equinoxes, the shadow is to the *gnomon* as 8 to 9: suppose, then, the *gnomon* TS to be 90 feet, and the shadow TV 80 feet, and we shall have the angle V equal to 48° 22', which is the height of the equator at Rome, and the elevation of the pole there is 41° 38'.

Riccioli takes notice of the following details in the observations of the sun's height, made with the *gnomons* by the ancients and those of the moderns: they did not reckon the sun's parallel, which makes his apparent altitude less, by the quantity of the parallel, than it would be, if the *gnomons* were placed at the centre of the earth: they did not consider refraction, by which the apparent height of the sun is a little increased; and they made their calculations from the length of the shadow, as if it were terminated by a ray coming from the centre of the sun's disk, whereas the shadow is really terminated by a ray coming from the upper edge of the sun's disk; so that, instead of the height of the centre of the sun, their calculations gave the height of the upper edge of his disk: and, therefore, to the altitude of the sun found by the *gnomons*, the sun's parallax must be added; and from the sum, the sun's semi-diameter and refraction, which is different in different altitudes, must be subtracted: consequently, the height of the equator at Rome, corrected, will be 48° 4' 13", the complement of which, or 41° 55' 47", is the elevation of the pole. Riccioli, *Geogr. ref. lib. vii. cap. 4.*

The preceding problem may be resolved more accurately thus: make a circular perforation in a brass plate, to transmit enough of the sun's rays to exhibit his image on the

the floor; fix it parallel to the horizon in a high place, proper for observation; then let fall a line and plummet, wherewith to measure the height of the perforation from the floor. Take care the floor be perfectly level and exactly horizontal, and let it be whitened over, to exhibit the sun more distinctly. Draw a meridian line thereon, passing through the foot or centre of the gnomon, i. e. through the point the plummet points out; note the extreme points of the sun's diameter on the meridian line K and I, and from each subtract a right line equal to the semi-diameter of the aperture; viz. K H (Tab. Astr. fig. 57.) on one side, and L I on the other. Then will H I be the image of the sun's diameter, which bisected in B, gives the point on which the rays fall from the centre of the sun.

Now having given the right line A B, and the altitude of the gnomon, with the angle A, which is right, the angle A B C, or the apparent altitude of the sun's centre, is easily found: for, assuming one of the given sides A B for radius, A G will be the tangent of the opposite angle B. Then say, as one leg, A B: is to the other A G: so is the whole line A C: to the tangent of the angle B.

GNOMONIC *calculus*. See **CALCULUM**.

GNOMONIC *peliphaen*. See **POLYPHAEON**.

GNOMONIC, or **GNOMONICAL projection**, that which represents the circles of a hemisphere, upon a plane touching it in the vertex, by lines or rays from the centre of the hemisphere to all the points of the circles to be projected.

In this projection, all the great circles of the sphere are projected into right lines. Any lesser circle parallel to the plane of projection is projected into a circle. And any lesser circle not parallel to the plane of projection, is projected into a conic section.

The *gnomonic projection* is also called the *horologigraphic projection*, because it is the foundation of **DIALLING**, in other respects it is not much used, because the circles of the sphere are projected into conic sections, which are difficult to describe. However this projection has its conveniences in the solution of some problems of the sphere, on account of the great circles being all projected into right lines.

Mr. Emerson, known by an ingenious treatise upon Fluxions, and a variety of other publications, has given the theory and practice of the *gnomonic projection*, in his Treatise on the Projection of the Sphere, Lond. 1749, 8vo.

GNOMONICA, *ἡμετερον*, or **GNOMONICS**, the art of **DIALLING**, or of drawing sun and moon-dials, &c. on any given plane.

It is thus called, as it shews how to find the hour of the day, &c. by the shadow of a gnomon or style.

GNOSIMACHIA, an ancient sect in religion, whose distinguishing character was, that they were professed enemies of all human knowledge in divinity.

The word is γνῶσιμα, &c. ἡ δὲ ἐχθρὸς ἐκείνου τοῦ λογισμοῦ.

Damascenus says, that they were perfectly averse to all the notions of Christianity, i. e. to all the science or technical knowledge thereof. They held it an useless labour to seek for gnosis in the holy scriptures; and said, that God requires nothing of men but good works; that it were, therefore, much better to walk with more simplicity, and not to be so solicitous about the dogmata of the gnostic life.

GNOSTICS, ancient heretics, famous from the first rise of Christianity, principally in the East.

It appears from several passages of the sacred writings, particularly 1 John ii. 18. 1 Tim. vi. 20. and Col. ii. 8. that many persons were infected with the *gnostic* heresy in the first century; though the sect did not render itself conspicuous either for number or reputation, before the time of Adrian, when some writers erroneously date its rise.

The word is formed of the Latin *gnoscere*, and that of the Greek γινώσκω, *knowing*, of *gnosis*; I know.

The name *gnostic* was adopted by those of this sect, as if they were the only persons who had the true knowledge of Christianity. Accordingly, they looked on all other Christians as simple, ignorant, and barbarous persons, who explained and interpreted the sacred writings in a too low, literal, and unedifying signification.

At first, the *gnostics* were only the philosophers and wits of those times, who formed themselves a peculiar system of theology, agreeable to the philosophy of Pythagoras and Plato; to which they accommodated all their interpretations of scripture.

GNOSTICS afterwards became a general name, comprehending diverse sects and parties of heretics, who rose in the first centuries, and who, though they differed among themselves as to circumstances, yet all agreed in some common principles. They were such as corrupted the doctrine of the gospel by a profane mixture of the tenets of the oriental philosophy, concerning the origin of

evil and the creation of the world, with its divine truths. Such were the **VALENTINIANS**, **SERAPIONIS**, **CARACRATIANS**, **NICOLAÏTANS**, &c.

GNOSTICS was sometimes also more particularly attributed to the successors of the first Nicolaïtans and Carpocratians, in the second century, upon their having added the names of the first authors. Such as would be thoroughly acquainted with all their doctrines, mysteries, and various, may consult St. Irenaeus, Tertullian, Clemens Alexandrinus, Origen, and St. Epiphanius, particularly the first of these writers, who relates their sentiments at large, and confutes them at the same time: indeed, he dwells more expressly on the Valentiniens than any other sort of *gnostics*; but he shews the general principles wherupon all their mystical opinions were founded, and the method they followed in explaining scripture. He accuses them with introducing into religion, certain vain and ridiculous genealogies i. e. a kind of divine processions or emanations, which had no other foundation but in their own wild imagination.

In effect, the *gnostics* confessed, that these zones or emanations were, where expressly delivered in the sacred writings; but infused at the same time, that Jesus Christ had insinuated them in parables to such as could understand him. They built their theology not only on the gospels and the epistles of St. Paul, but also on the law of Moses and the prophets.

Their law laws were peculiarly fervent to them, on account of the allegories and allusions with which they abound; which are capable of different interpretations. However, their doctrine concerning the creation of the world by one or more inferior beings of an evil or imperfect nature, led them to deny the divine authority of the books of the Old Testament, which contradicted this idle fiction, and led them with an abhorrence of Moses and the religion he taught; alledging, that he was seduced by the malignant author of this world, who consulted his own glory and authority, and not the real advantage of men. Their perdition that evil refused in matter, as its centre and source, made them treat the body with contempt, discourage marriage, and reject the doctrine of the resurrection of the body and its reunion with the immortal spirit. Their notion, that malignant gent precluded in nature, and occasioned diseases and calamities, wars, and delations, induced them to apply themselves to the study of magic, in order to weaken the powers or suspend the influence of these malignant agents.

The *gnostics* considered Jesus Christ as the Son of God, and, consequently, inferior to the Father, who came into the world for the rescue and happiness of miserable mortals, oppressed by matter and evil beings; but they rejected our Lord's humanity, on the principle that every thing corporeal is essentially and intrinsically evil; and, therefore, the greater part of them denied the reality of his sufferings. They set a great value on the beginning of the gospel of St. John, where they fancied they saw a great deal of their zones or emanations, under the Word, the Life, the Light, &c. They divided all nature into three kinds of beings, viz. *bylos*, or material; *psycic*, or animal; and *poimatic*, or spiritual.

On the like principle they also distinguished three sorts of men; *material*, *animal*, and *spiritual*. The first, who were material, and incapable of knowledge, inevitably perished, both soul and body; the third, such as the *gnostics* themselves pretended to be, were all certainly saved; the *psycic*, or animal, who were the middle between the other two, were capable either of being saved or damned, according to their good or evil actions.

With regard to their moral doctrines and conduct, they were much divided. The greater part of this sect adopted very austere rules of life, recommended rigorous abstinence, and prescribed severe bodily mortifications, with a view of purifying and exalting the mind. However, some maintained, that there was no moral difference in human actions; and thus, confounding right with wrong, they gave a loose rein to all the passions, and asserted the innocence of following blindly all their motions, and of living by their tumultuous dictates. They supported their opinions and practice by various authorities: some referred to fictitious and apocryphal writings of Adam, Abraham, Zoroaster, Christ and his apostles; others boasted that they had deduced their sentiments from secret doctrines of Christ, conveyed from the vulgar; others affirmed, that they arrived at superior degrees of wisdom by an innate vigour of mind; and others asserted that they were introduced in these mysterious parts of theological science by Theudas, a disciple of St. Paul, and by Matthias, one of the friends of our Lord. The tenets of the ancient *gnostics* were revived in Spain, in the fourth century, by a sect called the **PRISCILLIANISTS**. See Mosheim's *Eccles. Hist.* vol. I. p. 107, &c. edit. octavo, 1758.

The appellation *Gosfic* sometimes also occurs in a good sense, in the ancient ecclesiastical writers, and particularly Clemens Alexandrinus, who, in the person of his *Gosfic*, describes the characters and qualities of a perfect Christian. This point he labours in the seventh book of his *Stromata*, where he shews, that none but the *Gosfic*, or learned person, has any true religion. He affirms, that were it possible for a knowledge of God to be separated from eternal salvation, the *Gosfic* would make no scruple to choose the knowledge; and that if God would promise him impunity in doing of any thing he has once spoken against, or offer him heaven on those terms, he would never alter a whit of his measures.

In this sense the father uses *Gosfic*, in opposition to the heretics of the same name; affirming that the true *Gosfic* is grown old in the study of the holy Scripture; and that he preserves the orthodox doctrine of the apostles, and of the church; whereas the false *Gosfic* abandons all the apostolical traditions, as imagining himself wiser than the apostles.

At length the name *Gosfic*, which originally was the most glorious, became infamous, by the idle opinions and dissolute lives of the persons who bore it; much as, in the present age, it has faded with the name *quintiff*, *quintiff*, &c.

GO, in *Ichthyography*, a name given by some to the common rock-fish, or sea-gudgeon. See *GOCYR*.

Go is sometimes used, in *Law*, in a special signification. Thus, to go with *ad*, and to go *in* *God*, denote as much as to be dismissed the court, and to be acquitted.

GOACONEZ, in *Botany*, the name of an American tree, which abounds a white balsam, but little known in Europe; it is called by some authors *balsamum alium*, and by others *balsamum paria*.

GOAD, *Stimulus*, a stick armed at one end with a pointed iron, to prick and urge on oxen, and other cattle.

GOALS. See *GAS*.

GOAN, the name of a Persian tree, of the ashes of which they make a sort of antipodion, or medicinal powder, for diseases of the eyes.

GOARING, on ship-board. The seamen say a fall is cut *gearing*, when it is cut sloping by degrees, and is broader at the clew than at the cat-ting, as all top-sails and top gallant-sails are.

GOAT, *Capra*, in the Linnean system of *Zoology*, makes a distinct genus of animals of the order of the *ovina*, the distinguishing characters of which are, that its horns are hollow, turned upward, and not smooth, but annulated on their surface; that it has eight cutting teeth in the lower jaw, and none in the upper, and that the male is generally bearded. This genus comprehends all the goat kind, the *gazelle*, *ibex*, *capra*, &c. the characters of which, according to Mr. Ray, are these; that it is covered with hairs, not with wool; that its horns are less crooked than those of the sheep, and that it has a beard hanging down from its chin, and is of a strong smell.

It is very singular that this genus of animals are all able to run and climb about the rugged parts of mountains without falling, though their feet seem by no means contrived by nature for any such purposes. Linnaeus enumerates twelve known species of this animal. 1. The *capra hircus*, or common kind, sufficiently known. Linnaeus reckons the *Angora goat* of Asiatic Turkey a variety of this: the hair of this animal is of a silky fineness and silvery whiteness, in curled locks of eight or nine inches in length, and forms the basis of our fine *cashmere*. The hair is imported in form of thread, for the Turks will not suffer it to be exported raw, because the spinning employs multitudes of poor. This variety is confined to a district of two or three days journey in extent; for if they change climate, the hair grows coarser.

2. The *capra montana*, or Syrian goat. This is remarkable for the length of its ears, which reach almost to the ground, and are very like those of the common hunting hound; the horns are black and short, and are very little inflected backwards; it is of the shape of the common goat, but larger; its colour that of the fox, and is a creature easily tamed, and feeds on hay and other vegetables. This species is very common in the East, and supplies the inhabitants of Aleppo with milk. 3. The *capra deserta Africana*, or African goat, described in the German Ephemerides; it is of a dusky grey colour, and has a bundle of erect hairs growing on the middle of its head; and on each side, between the eyes and nose, it has two cavities, which contain a thick, fat, yellowish liquor, which afterwards congeals into a black substance, of a mixed smell between those of milk and callos. As soon as the matter contained in these cavities is taken away, there returns more in its place, which is in like manner dried and hardened by the air. These cavities have no communication with the eyes, and therefore the matter described here is nothing of the nature of the *Vol. II. N° 154.*

elyma cervi, mentioned in the catalogues of the materia medica. This creature is figured without horns, because they are very small, and scarce perforate the skin. The male of this species is covered with rough hair; and beneath the chin hang two long hairy wattles; the hair of the female is smooth, its horns less, and it has no wattles. 4. The *capra cretensis*, which is also African; with short smooth horns, turning a little forwards. Linnaeus says, that these two last species came from America; but Mr. Pennant observes, that the *goat*, and every other domestic animal was unknown in that country, before its discovery by the Spaniards. 5. The *ibex*, or wild goat.

6. The *capra*. See *CHAMOIS* and *EGAGROPILA*. 7. The *capra gazelle*, or Indian antelope. 8. The *capra cervicapra*, or African antelope, with upright horns, twisted spirally, and surrounded almost to the top with prominent rings; the face of this animal is rather less than that of the fallow deer, or buck; its colour, brown mixed with red, and dusky; the belly and inside of the thighs white; the tail short, black above, and white below; the female wants horns. 9. The *capra leucosticta*, with very long slender, upright horns, bending at the upper part inward towards each other; some are much annulated, and others smoother. This animal is of the size of the common goat, and its colour is red mixed with ash-colour. It inhabits the inhospitable mountains of Laar, in Persia, and produces the *STROGA*.

10. The *capra arvensis*, or African gazelle of Ray, with round horns, inclining first backwards, bending in the middle, reverting forwards at their ends, and annulated. See *GAZELLE* and *ANTELOPE*. 11. The *capra tartarica*, Scythian antelope, *ibex imberbis*, or *ibex* of Buffon, is a species of goat with horns, about a foot long, bending in the middle, the points inclining upwards, the ends smooth; the other part surrounded with prominent annuli, of a pale yellow colour, and for the most part semipellucid. The head of this animal is like that of a sheep; its nose large and arched, marked through its whole length with a small line, caused by the elevation of the *septum narium*; the nostrils large; the upper lip hangs over the under, and the cutting teeth are so loose in their sockets as to move with the least touch. The male is covered with rough hair, and has a strong smell; the female is smoother, timid, and without horns; when attacked by wolves or dogs, the males place them in a circle, stand round them, and defend them. The skin is soft, and excellent for gloves, belts, &c. They are found in flocks of many thousands between the Tanaïs and Dniestres. See *Phil. Trans.* 1767, p. 344.

12. The *capra amurensis*, the *musman* of Pliny, the *tragelaphus* of Belon, or Siberian goat, with large horns, bending backwards, close at their base, distant at their points, with circular rings, or folds. This animal is of the height and size of the ram, covered with pale, ferruginous, long hair; the hind legs, belly, and rump, are white; the tail is short and black. The horns of the male are much larger than those of the females. These animals inhabit the north-east parts of Asia, Barbary, Sardinia, Corsica, and Greece; they live in the mountains, and run swiftly among the rocks. They are supposed by M. Buffon to be the sheep in a wild state.

Goats may be of great advantage to farmers in some parts of the kingdom, as they will live in rocky barren countries, where nothing else can get a support for life. They will climb the steepest rocks, and there browse upon briars, heath, and shrubs, of various kinds, which other creatures will not taste of. They will feed on grass in pastures; but as they love browsing on trees much better, great care must be taken to keep them from valuable plantations.

The rutting season of these animals is from the beginning of September to November; they go with young four months and a half, and bring forth from the latter end of February to the latter end of April. They are much affected by the weather; a rainy season makes them thin; and a dry sunny season makes them fat and blythe; they are very libidinous animals, and seldom live in our climate above eleven or twelve years.

The best kind of goat for keeping to advantage should be chosen in this manner: the male should have a large body, his hair should be long, and his legs straight and stiff; the neck should be plain and short, the head small and slender, the horns large, the eyes prominent, and the beard long. The female should have a large udder, with large teats, and no horns, or very small ones. They should be kept in flocks, that they may not straggle, and they should have good shelter both in summer and in winter, the heat and cold being both prejudicial to them. They should have no litter in winter, but only a paved floor kept clean. The kids are to be brought up for the table in the same manner as our lambs are. They are recommended to lie among horses, as their smell, as is supposed,

sapped, prevents many distempers in those animals. The greatest advantage of these creatures is their milk, which they yield in large quantities. It is sweet, nourishing, and medicinal; an excellent feed-draught for calves; and has been, with a tea-spoon full of lard, drunk warm in bed in the morning, and at four in the afternoon, and thus repeated for some time, a cure for phlegmatic people, before their disorder has become inveterate. In some parts of Scotland, Ireland, and Wales, the milk is made into whey, which has been of great service in this and other cases, where coolers and restoratives are necessary. The blood of the he-goat, dried, has been recommended for the pleurisy and inflammatory disorders, and is taken notice of by Dr. Mead in this intention.

They mix *goat's* milk and cow's milk together in many parts of the kingdom, and a very valuable kind of cheese is made of it. Beside this, the kids or young *goats* are very fine food, and the best kinds bring forth these two or three at a time, and that twice a year.

The hunches of the *goat* are frequently fished and dried in some parts of Wales, where it is called *hung venison*. The flesh of a fishy *goat*, six or seven years old, is reckoned the best, and is generally very sweet and fat. It is called *rock-venison*, and is little inferior to that of the deer. The flesh of *goats*, killed about four or five years old, is in great esteem, and makes excellent candles. *Goat* hair also is of value; it may be threaded as the wool from sheep, and is excellent for making ropes that are to be used in the water, as they will last a great while longer than these made in the common way. A sort of flax is also made of it in some places.

The whitest wigs are made of the hair of the male *goats*; the whitest and clearest is selected from that which grows on the hunches, where it is longest and thickest. That of the Welsh *goats* is preferable to all others, both in length and fineness. The horns are also used for the handles of rucks and pen-knives; and the hair is applied to various uses by glovers. See Mortimer's *Hist.* p. 240, 241. Pennant's *British Zool.* vol. 1. p. 30, 31.

GOAT of Greenland, capra Greenlandica, in *Zoology*, the name of an animal of the northern parts of the world. We are not perfectly acquainted with the shape or figure of the creature; but its horns are preserved in the museum of the Royal Society, and in some other collections, and are usually an ell long, very much branched, and the branches not flat but rounded, covered all over with a velvety down, composed of short filaments standing erect every way, and about a quarter of a finger's breadth long.

GOAT-fish, Capri-fish, in *Ichthyography*, the name of a fish, called also by some *caper*. In the middle of its back it has three very strong and large prickles, the first of which is three times as large as any of the others, and all are connected by a membrane. See *Fish*, N° 5.

The whole fish is covered with a scaly skin; but the scales have more the appearance of those of a serpent, than those of the fish; for they are placed in cancellated lines intersecting one another, and are so well fixed, that they with difficulty come off; and wood or ivory may be polished with the skin, as with the common fish-skin used by the turners, &c. It is of a bluish-green colour, spotted with a fine blue, and the back and belly-fins are black, with some blue and red spots. Its whole figure is very broad and flat, as well as short, so that it approaches to a round form. It seldom exceeds two pounds in weight. It is caught in the Mediterranean, but not commonly. The skin of it is frequently found in the cabinets of the curious.

GOAT-fisher, in *Zoology*, a name by which the *caprimulgus* is called in some parts of England; but its more usual name with us is the *chero-w-o-l*.

GOAT-thorn, Tragacantha, in *Botany*, a genus of the *fumifera polygamia aquina* class. Its characters are these: the common empalement of the flower is single, composed of eight acute-pointed leaves, which are alternately larger, joined at their base; the flower is composed of many hermaphrodite florets, which are uniform, of one petal, stretched out like a tongue, indented at the points in five parts, and lying over each other like the scales of fish; these have each five short hair-like filamina, terminated by cylindrical summits, and an oblong germin situated under the floret, supporting a slender style the length of the filamina, crowned by two revolving stigmas: the empalement of the flower afterwards swells to a belly, including many oblong, angular, rough seeds, slender at both ends, crowned by a feathery down. Miller enumerates fix, and Linnaeus eleven species.

There are two or three species of this plant well known among us, the one wild in our meadows and pastures, by the name of *go* is held in *reue*, from its flowers always shutting up in the middle of the day; another kept in our

gardens for its beautiful red flowers; and a third cultivated for its excellent root, and known by the name of *salady*. This was originally from Italy, and is still kept in many gardens as a good root; but it is not common in our markets.

These plants are propagated by sowing their seeds in spring on an open spot of ground. The *salady* should be sowed in rows at nine or ten inches distance; and when the plants are come up, they should be left at about six inches asunder in the rows; they then require no farther care but to be kept clear from weeds; and if the soil be light, and not too dry, they will grow to a considerable size by winter. The roots are to be taken up for use when the leaves are decayed, and continue in fashion till March; and then the young shoots, which are very large and thick, are by many boiled as asparagus, and make a very delicate dish. Miller.

GOAT's eye. See *EYE*.

GOAT's ear, Galaea, in *Botany*, a genus of the *diadelphica deandria* class. Its characters are these: the flower is of the butterfly kind; the standard oval, large, and reflexed; the wings are near the length of the standard; the keel erect, oblong, and compressed; and hath ten stamens which join above their middle; in the center is situated a narrow, cylindrical germin, which afterward becomes a long pointed pod, including several oblong kidney-shaped seeds. Miller reckons three species, natives of warm climates, and Linnaeus ten.

In medicine, the constant use, with blue flowers, is esteemed a great alexipharmic and sudorific. It is much used in Italy; but amongst us only as an ingredient in some compositions.

Mr. Boyle celebrates the virtues of *goat's ear* in pellucidal and malignant diseases, from his own observation and experience.

GOAT's horn, greater. See *SATYRIUM*.

GOAT's horn, lesser. See *ORCHIS*.

GOAT's thorn, Tragacantha, in *Botany*. Its characters are these: the empalement of the flower is indented in five parts, the lower segments being the shortest; the flower is of the butterfly kind, the standard long, erect, and indented at the point; the borders reflexed; the wings shorter than the standard; the keel is of the same length with the wings, and is indented; it has ten filamina, nine of them joined, and one separated, terminated by roundish summits; and a sharp point germin, supporting an awl-shaped style, crowned by an obtuse stigma. The germin afterward becomes a short swelling pod, having two longitudinal cells, including kidney-shaped seeds. There are four species. Linnaeus has joined this genus to that of *ASTRAGALUS*.

From one species of this genus, M. Tournefort says the gum adragant, or dragon, is produced in Crete. See *TRAGACANTH*.

GOBELINS, a celebrated manufactory, established at Paris, in the Faubourg St. Marcel, for the making of *TAPETRY*, and other furniture for the use of the crown. The house where this manufactory is carried on, was built by two brothers, Gilles and John *Gobelins*, both excellent dyers; and the first that brought to Paris, in the reign of Francis I. the secret of dying that beautiful scarlet colour still known by their name; as well as the little river *lievre*, on whose banks they fixed their dye-house; and which is now known by no other name than that of the river of the *Gobelins*.

It was in the year 1667 that this place, till then called *Gobelins Faub*, changed its name into that of *Hôtel Royal des Gobelins*, in consequence of an edict of Louis XIV. Mons. Colbert having re-established, and with new magnificence enriched and completed the king's palaces, particularly the Louvre and Tuilleries, began to think of making furniture suitable to the grandeur of these buildings; with this view he called together all the ablest workmen in the direct arts and manufactures throughout the kingdom; particularly painters, tapestry-makers, sculptors, goldsmiths, chemists, &c. and by splendid offers, pensions, privileges, &c. called others from foreign nations.

And to render the intended establishment firm and lasting, he brought the king to purchase the *exclusive* for them to work in, and draw up a system of laws, or policy, in seventeen articles.

By these it is provided, that the new manufactory shall be under the administration of the superintendent of the king's buildings, art, &c. that the ordinary matters thereof shall take cognizance of all actions and processes brought against any of the persons in the said manufactory, their servants and dependants; that no other tapestry work shall be imported from any other country, &c.

The *Gobelins* has ever since remained the first manufactory of this kind in the world. The quantity of the finest

"He is omnipresent, not only virtually, but also substantially; for power without substance cannot subsist. All things are contained, and move, in him; but without any mutual passion: he suffers nothing from the motions of bodies; nor do they undergo any resistance from his omnipresence.

"It is confessed, that God exists necessarily; and by the same necessity he exists always, and every where. Hence, also, he must be perfectly similar; all eyes, all ear, all brain, all arm, all the power of perceiving, understanding, and acting; but after a manner not at all corporeal, after a manner not like that of men, after a manner wholly to us unknown.

"He is destitute of all body, and all bodily shape; and therefore cannot be seen, heard, nor touched; nor ought to be worshipped under the representation of any thing corporeal.

"We have ideas of the attributes of God, but do not know the substance even of any thing: we see only the figures and colours of bodies, hear only sounds, touch only the outward surfaces, smell only odours, and taste tastes; and do not, cannot, by any sense, or any reflex act, know their inward substances; and much less can we have any notion of the substance of God.

"We know him by his properties, and attributes; by the most wise and excellent structure of things, and by final causes; but we adore and worship him only on account of his dominion: for God, setting aside dominion, providence, and final causes, is nothing else but fate and nature." Newt. Princ. Nat. Princip. Math. n. calc.

An ingenious divine has wrought these thoughts of that admirable philosopher into form, and ripened them into a more explicit system, in a discourse on this subject. Maxwell's Disc. concerning God.

We shall here furnish a compendious abstract of the principal arguments that have been adduced in proof of the existence of God. The admirable metaphysician and divine, Dr. Clarke, has demonstrated this truth, with that clearness and force of reasoning, for which he is so eminently distinguished, by a series of propositions, mutually connected and dependent, and forming a complete and unanswerable argument in proof both of the being and attributes of the Deity. 1. Something has existed from all eternity; for, since something now is, something always was: otherwise the things that now are must have been produced out of nothing, absolutely and without cause; which is plain contradiction in terms. 2. There has existed from eternity some one unchangeable and independent being; or else, there has been an infinite succession of changeable and dependent beings produced one from another in an endless progression, without any original cause at all. From without, this series of beings can have no cause of its existence, because it includes all things that are or ever were in the universe: nor is any one being in this infinite succession self-existent or necessary, and therefore it can have no reason of its existence within itself; and it was equally possible, that from eternity there should never have existed any thing at all, as that a succession of such beings should have existed from eternity. Consequently, their existence is determined by nothing; neither by any necessity of their own nature, because none of them are self-existent; nor by any other being, because no other is supposed to exist. 3. That unchangeable and independent being, which has existed from eternity, without any external cause of its existence, must be self-existent, i. e. it must exist by an absolute necessity originally in the nature of the thing itself, and antecedent in the natural order of our ideas to our supposition of its being. For whatever exists must either have come into being out of nothing without causes, or it must have been produced by some external causes; or it must be self-existent: but the two former suppositions are contrary to the two first propositions. From this last proposition it follows, that the only true idea of a self-existent, or necessarily existing being, is the idea of a being, the supposition of whose non-existence is an express contradiction; and this idea is that of a most simple being, absolutely eternal and infinite, original and independent. It follows *visu*, that nothing is so certain as the existence of a supreme independent cause; and likewise, that the material world cannot possibly be the first and original being, uncreated, independent, and of itself eternal; because it does not exist by an absolute necessity in its own nature, so that it must be an express contradiction to suppose it not to exist. With respect both to its form and matter, the material world may be conceived not to be, or to be in any respect different from what it is, without a contradiction. 4 and 5. The substance or essence of the self-existent being is absolutely incomprehensible by us; nevertheless, many of the es-

sentia attributes of this nature are strictly demonstrable, as well as his existence. The self-existent being, having no cause of its existence but the absolute necessity of its own nature, must of necessity have existed from everlasting, without beginning; and must of necessity exist to everlasting, without end. 6. The self-existent being must of necessity be infinite and omnipresent. Such a being must be every where, as well as always, unalterably the same. It follows from hence, that the self-existent being must be a most simple, unchangeable, incorruptible being; without parts, figure, motion, divisibility, and other properties of matter, which are utterly inconsistent with complete infinity. 7. The self-existent being must of necessity be but one; because in absolute necessity there can be no difference or diversity of existence; and, therefore, it is absolutely impossible, that there should be two independent, self-existent principles, such, e. g. as God and matter. 8. The self-existent and original cause of all things must be an intelligent being.

This proposition cannot be demonstrated strictly and properly *a priori*; but *a posteriori*, the world affords undeniable arguments to prove that all things are the effects of an intelligent and knowing cause. The cause must be always more excellent than the effect; and, therefore, from the various kinds of powers and degrees of excellence and perfection, which visible objects possess, from the intelligence of created beings, which is a real distinct quality or perfection, and not a mere effect or composition of unintelligent figure and motion; from the variety, order, beauty, wonderful contrivance, and fitness of all things to their proper and respective ends; and from the original motion, the self-existent creating being is demonstrated to be intelligent. 9. The self-existent and original cause of all things is not a necessary agent, but a being endued with liberty and choice. Liberty is a necessary consequent of intelligence: without liberty, no being can be said to be so agent, or cause of any thing; since to act necessarily is really and properly not to act at all, but to be acted upon. Besides, if the supreme cause be not endued with liberty, it will follow, that nothing which is not could possibly have been; that nothing which is could possibly now have been; and that no mode or circumstance of the existence of any thing could possibly have been in any respect otherwise than it now actually is. Farther, if there be any final cause in the universe, the supreme cause is a free agent; and on the contrary supposition, it is impossible that any effect should be finite; and in every effect, there must have been a progression of causes in *seculo*, without any original cause at all. 10. The self-existent being, the supreme cause of all things, must of necessity have infinite power; since all things were made by him, and are entirely dependent upon him; and all the powers of all things are derived from him, and perfectly subject to him; nothing can resist the execution of his will. 11. The supreme cause and author of all things must of necessity be infinitely wise. This follows from the propositions already established; and the proof *a posteriori*, of the infinite wisdom of God, from the consideration of the exquisite perfection and consummate excellency of his works, is no less strong and undeniable. 12. The supreme cause and author of all things must of necessity be a being of infinite goodness, justice, and truth, and all other moral perfections; such as become the supreme governor and judge of the world. The will of a being, infinitely knowing and wise, independent and all-powerful, can never be influenced by any wrong affection, and can never be misled or opposed from without; and, therefore, he must do always what he knows first to be done; that is, he must act always according to the strictest rules of infinite goodness, justice, and truth, and all other moral perfections; and more particularly, being infinitely and necessarily happy and all-sufficient, he must be unalterably disposed to do, and to communicate good or happiness. See Clarke's Demonstration of the Being and Attributes of God, psalm.

To this more subtle argument *a priori*, for the existence of God, we may add another, more generally obvious, and carrying irresistible conviction, which is deduced from the frame of the universe, and from the traces of evident contrivance and fitness of things for one another, that occur through all the parts of it. These *conspire* to prove, that the material world, which in its nature is originated and dependent, could not have been the effect of chance or necessity, but of intelligence and design. The beautiful, harmonious, and beneficial arrangement of the various bodies, that compose the material system; their mutual dependence and subserviency; the regularity of their motions, and the aptitude of these motions for producing the most beneficial effects; and many other phenomena resulting from their relation, magnitude, situation, and use, afford unquestionable evidences of the creating

creating power and wise disposal of an intelligent and almighty agent. The power of gravity, by which the celestial bodies persevere in their revolutions, deserves our particular consideration. This power penetrates to the centre of the sun and planets, without any diminution of its virtue, and is extended to immense distances, regularly decreasing, and producing the most sensible and important effects. Its action is proportional to the quantity of solid matter in bodies, and not to their surfaces, as is usual in mechanical causes; and, therefore, seems to surpass mere mechanism. But however various the phenomena that depend on this power, and may be explained by it, no mechanical principles can account for its effects: much less could it have produced, at the beginning, the regular situation of the orbits, and the present disposition of things. Gravity could not have determined the planets to move from west to east in orbits nearly circular, almost in the same plane: nor could this power have projected the comets with all the variety of their directions. If we suppose the matter of the system to be accumulated in the centre by its gravity, no mechanical principles, with the assistance of this power, could separate the huge and unwieldy mass into such parts as the sun and planets; and after carrying them to their different distances, project them in their several directions, preserving still the equality of action and reaction, or the state of the centre of gravity of the system. Such an exquisite structure of things could only arise from the contrivance and powerful influence of an intelligent, free, and most potent agent. The same powers, therefore, which at present govern the material universe, and conduct its various motions, are very different from those which were necessary to have produced it from nothing, or to have disposed it in the admirable form in which it now exists.

But we shall far exceed the proper limits of this article, if confining our observation to the earth, our own habitation, we were to enumerate the principal traces of design and wisdom, as well as goodness, which are discernible in its figure and constituent parts, in its diurnal and annual motion, in the position of its axis with regard to its orbit, in the benefit which it derives from the light and heat of the sun, and the alternate vicissitude of the seasons; in the atmosphere which surrounds it, and in the different species and varieties of vegetables and animals with which it is replenished. No one can survey the vegetable productions of the earth, so various, beautiful, and useful; nor the various gradations of animal life, in such a variety of species, all preserved distinct, and propagated by a settled law, each fitted to its own element, provided with proper food, and with instincts and organs fitted to its rank and situation, and especially with the powers of sensation and self-motion, and all more immediately or remotely subservient to the government and use of man, without admiring the skill and design of the original Former. But there are more signally manifested in the structure of the human frame, and in the noble powers and capacities of the human mind; more especially in the moral principles and faculties, which are a distinguishing part of our constitution, and lead to the perception and acknowledgement of the existence and government of God. In those instances that have now been recited, and a variety of similar instances suggested by them, or naturally occurring to the notice of the curious and reflecting mind, contrivance is manifest, and immediately, without any nice or subtle reasonings, suggests a contriver. It strikes us like a sensation; and artful reasonings against it may puzzle us, without shaking our belief. No person, for example, that knows the principles of optics, and the structure of the eye, can believe that it was formed without skill in that science; or that the ear was formed without the knowledge of sounds; or that the male and female, created and preserved in due proportion, were not formed for each other, and for continuing the species. All our accounts of nature are full of instances of this kind. The admirable and beautiful structure of things for final causes, exalts our idea of the contriver; and the unity of design shews him to be one. The great motions in the system, performed with the same facility as the least, suggest his almighty power, which gave motion to the earth and the celestial bodies, with equal ease as to the minutest particles; the subtilty of the motions and actions in the internal parts of bodies, shews that this influence penetrates the inmost recesses of things, and that he is equally active and present every where. The simplicity of the laws that prevail in the world, the excellent disposition of things, in order to obtain the best ends, and the beauty which adorns the works of nature, far superior to any thing in art, suggest his consummate wisdom. The usefulness of the whole scheme, so well contrived for the intelligent beings who enjoy it, with the internal disposition and mo-

ral structure of those beings, shews his unbounded goodness. These are arguments which are sufficiently open to the views and capacities of the unlearned, while, at the same time, they acquire new strength and lustre from the discoveries of the learned. The Deity's acting and interposing in the universe shew that he governs it as well as formed it; and the depth of his counsels, even in conducting the material universe, of which a great part surpasses our knowledge, tends to preserve an inward veneration and awe of this great being, and disposes us to receive what may be otherwise revealed to us concerning him. His efficacy, as well as that of all other substances, is beyond the reach of all our discoveries: but his attributes clearly appear in his admirable works. We know that the highest conceptions we are able to form of them are still beneath his real perfections; but his dominion over us, and our duty towards him, are manifest. See *Marshall's Account of Sir I. Newton's Phil. Diss.* book iv. chap. 9.

Those who wish to see the argument, which has been now sketched out in some of its leading outlines, more fully illustrated and urged, may consult the works of Rev. Ninewenty, Pastor in his Matho, Derham, De la Pluche in his *Nature displayed*, &c.

Another argument to prove the existence of God, as the creator and governor of the universe, may be deduced from the universal consent of mankind, and the uniform tradition of this belief through every nation and every age. It is impossible to conceive, that a tallage, so perpetual and universal, should be imposed on the united reason of mankind. No credible and satisfactory account can be given of this universal consent, without ascribing it to the original constitution of the human mind, in consequence of which it cannot fail to discern the existence of a deity, and to the undeniable traces of his being, which his works afford. Fear, state policy, and the prejudices of education, to which the concurrence of mankind in this principle has been sometimes resolved, are founded on this universal principle, suppose its being and influence, and are actuated by it. It is much more reasonable to imagine, that the belief of a God was antecedent to their operation than that it should have been produced by them; and that it was dictated by reason and conscience, independently of the passions and policy of men. The uniform and universal tradition of this belief, and of the creation of the world by the divine power, affords concurring evidence both of the principle and of the fact.

The existence of God is also farther evinced by those arguments which have been usually alleged to prove, that the world had a beginning, and, therefore, that it must have been created by the energy of divine power. In proof of this, the history of Moses, considered merely as the most ancient historian, deserves particular regard. His testimony is confirmed by the most ancient writers among the heathens, both poets and historians. It may be also fairly alleged, that we have no history or tradition more ancient than that which agrees with the received opinion of the world's beginning, and of the manner in which it was produced; and that the most ancient histories were written long after that time. And this consideration is urged by Lucretius, the famous Epicurean, as a strong presumption that the world had a beginning:

— Si nulla fuit gentiliū origo
Terrarum & cæli, imperque æterna furor;
Cur supra hecūm Titianum, & Jovis Troja,
Non alias aliis quoque res æternæ potius?

Besides, the origin and progress of learning, and the most useful arts, confirm the notion of the world's beginning, and of the common era of its creation; to which also may be added, that the world itself, being material and corruptible, must have had a beginning; and many phenomena occur to the observation of the astronomer and natural historian, which furnish a strong presumption, that it could have had no long duration, and that it gradually tends to dissolution. From all these considerations we may infer the existence, attributes, and providence of God.

God is also used in speaking of the false deities of the heathens, many of which were only creatures to which divine honours and worship were superstitiously paid. The Greeks and Latins, it is observable, did not mean, by the name God, an all-perfect being, whereof eternity, infinity, omnipresence, &c. were essential attributes: with them, the word only implied an excellent and superior nature; and, accordingly, they give the appellation *gods* to all beings of a rank, or class, higher and more perfect than that of men; and especially to those who were inferior agents in the divine administration, all subject to the one supreme.

Thus men themselves, according to their system, might

become *gods*, after death; inasmuch as their souls might attain to a degree of excellence superior to what they were capable of in life.

The first *divines*, (after Boëtius observes), were the poets; the two functions, though now separated, were originally combined; or, rather, were one and the same thing.

Now the great variety of attributes in *God*, that is, the number of relations, capacities, and circumstances, wherein they had occasion to consider him, put their poets, &c. under a necessity of making a partition, and of separating the divine attributes into several persons; because the weakness of the human mind could not conceive so much power and action in the simplicity of one single divine nature.

Thus the omnipotence of *God* came to be represented under the person and appellation of Jupiter; the wisdom of *God*, under that of Minerva; the justice of *God*, under that of Juno.

The first idols, or false *gods*, that are said to have been adored, were the stars, sun, moon, &c. on account of the light, heat, and other benefits which we derive from them.

Afterwards the earth came to be deified, for furnishing fruits necessary for the subsistence of men and animals; then *FIRE* and *WATER* became objects of divine worship, for their usefulness to human life.

In process of time, and by degrees, *gods* became multiplied to infinity; and there was scarce any thing but the weakness, or caprice, of some devotee or other, elevated into the rank of deity; things useful, or even destructive, not excepted.

The principal of the ancient *gods*, whom the Romans called *dei magni gentium*, and which Cicero calls *dei celestes*, were *Jove*, *Jupiter*, *Juno*, *Vesta*, *Minerva*, *Ceres*, *Diana*, *Venus*, *Mars*, *Mercury*, *Neptune*, *Vulcan*, and *Apollo*.

Jupiter is considered as the *god* of heaven; Neptune as *god* of the sea; Mars as the *god* of war; Apollo of eloquence, poetry, and physics; Mercury of thieves, Bacchus of wine, Cupid of love, &c.

A second sort of *gods*, called *dei medi-genti*, *feminae*, *dei minorum gentium*, *inferi*, or *gods* adopted; were men captured and deified. As the greater *gods* had possession of heaven by their own right; these secondary deities had it by right and donation; being translated into heaven because they had lived as *gods* upon earth.

The heathen *gods* may be all reduced to the following classes.

1. Created spirits, angels, or demons; whence good and evil *gods*; Genii, Lares, Lemures, Typhuses, guardian *gods*, infernal *gods*, &c.

2. Heavenly bodies; as the sun, moon, and other planets: also the fixed stars, constellations, &c.

3. Elements; as air, earth, ocean, Ops, Vesta; the rivers, fountains, &c.

4. Meteors. Thus the Persians adored the wind; thunder and lightning were honoured under the name of Geryon; and several nations, of India and America, have made themselves *gods* of the same. Castor, Pollux, Helena, and Isis, have also been preferred from meteors to be *gods*; and the like has been practised in regard to comets: witness that which appeared at the murder of Cæsar. Socrates deified the clouds; if we may give credit to Aristophanes; and the primitive Christians, Tertullian assures us, were reproached with the same thing.

5. They erected minerals, or fossils, into deities. Such was the Betylus; the Finlanders adored stones; the Scythians iron; and many nations silver and gold.

6. Plants have been made *gods*. Thus leeks and onions were deities in Egypt; the Scythians, Lithuanians, Celts, Vandals, and Peruvians, adored trees and forests: the ancient Gauls, Britons, Druids, bore a particular devotion to the oak; and it was no other than wheat, corn, feed, &c. that the ancients adored under the names of Ceres and Proserpina.

7. They took themselves *gods* from among the vipers. The Syrians and Egyptians adored snakes; and the Tritons, Nereids, Sirens, &c. what were they but fishes! Several nations have adored serpents; particularly the Egyptians, Persians, Lithuanians, Samogitians, &c.

8. Insects, as flies, and bees, had their priests, and votaries; these among the Thracians, and those in Acarnania, where bullocks were offered to them.

9. Among birds, the hawk, raven, the sparrowhawk, ibis, eagle, griffin, and lapwing, have had divine honours; the last in Mexico, the rest in Egypt, and at Thebes.

10. Four-footed beasts have had their altars; as the bull, dog, cat, wolf, baboon, lion, and crocodile, in Egypt; and elsewhere, the hog in the island of Cete; rats and

mice in the Troas, and at Tenedos; weasels at Thebes, and the porcupine throughout all Zoroaster's school.

11. Nothing was more common than to place men among the number of deities; and from Belus or Béal, to the Roman emperors before Constantine, the instances of this kind are innumerable; frequently they did not wait so long as their death for the apotheosis. Nebuchadnezzar procured his statue to be worshipped while living; and Virgil shows that Augustus had altars and sacrifices offered to him, *Ecl. i. l. 7*. As we learn, from other hands, that he had priests called *Augustales*; and temples, at Lyons, Narbonne, and several other places; and he must be allowed the first of the Romans, in whose behalf idolatry was carried to such a pitch. The Ethiopians deified all their kings *gods*; the Velleda of the Germans; the Janus of the Hungarians; and the Thau, Woden, and Aia, of the northern nations, were, indisputably, men.

12. Not men only, but every thing that relates to man, has also been deified: as labour, sleep, youth, age, death, virtues, vices, occasions, time, place, numbers, among the Pythagoreans; the generative power, under the name of Priapus. Infancy, alone, had a cloud of deities; as Vegetanus, Lævana, Rumex, Edusa, Potius, Culus, Cumina, Carna, Ophalea, Stullulus, Fabullinus, &c.

They also adored the *gods* health, fever, fear, love, pain, indignation, shame, impudence, opinion, temerity, prudence, science, art, fidelity, felicity, calamity, liberty, money, war, peace, victory, triumph, &c. Lastly, nature, the universe, or *universum*, was reputed a great *god*.

Herodotus has a poem under the title of *gods*, i. e. the generation of the *gods*; wherein he explains their genealogy and descent; sets forth who was the first, and principal, who next descended from him, and what share each had: the whole making a sort of system of heathen theology.

Beside this popular theology, each philosopher had his system: as may be seen from the Timæus of Plato, and Cicero De Natura Deorum.

Justin Martyr, Tertullian in his Apologies; and in his book Contra Gentes; Arnobius, Minucius Felix, Lactantius, Eusebius, Prepar. et Demonstr. Evangel. St. Augustine De Civit. Dei, and Theodoret Advers. Gentes, shew the vanity of the heathen *gods*.

It is very difficult to discover the real sentiments of the heathens, with respect to their *gods*; they are exceedingly intricate and confused, and even frequently contradictory. They admitted no many superior and inferior *gods*, who shared the empire, that all was full of *gods*. Varro reckons up no less than 3000 adored within a small extent of ground, and yet their number was every day growing. The way to heaven was so easy for the great men of those days, that Juvenal brings in Atlas complaining he was ready to sink under the load of such a number of new *gods* as were daily placed in the heavens; yet father Montaigne seems to have proved that all the philosophers of antiquity, have acknowledged that there was but one *god*. Plan. Theol. des Sect. Savants. de la Grece.

GOD, *act. of*. See DEABILITY.

GOD, *pass. of*. See PEACE.

GOD, *sem. of*. See SON.

GOD, *truth of*. See TRUTH.

GOD, *worship of*. See WORSHIP.

GOD-BOTTLE, in our Ancient Seamen Customs, an ecclesiastical or church fine, for crimes and offences committed against *God*.

GODDESS, *dea, diæa*, a heathen deity, to whom they attributed the female sex.

The ancients had almost as many *goddesses* as *gods*. Such were Juno, the *goddess* of air; Diana, the *goddess* of woods and chastity; Proserpina, the *goddess* of hell; Venus, of beauty; Fortia, of the Sea: such also were Victory, Fortune, &c.

Nay, they were not contented to make women *gods*, and admit both sexes into the roll; but they had also hermaphrodite *gods*. Thus, Nimmera, according to several of the learned, was both man and woman, and worshipped both under the appellation of Idm and Luma. Mithras, the Persian deity, was both *god* and *goddess*; and the sexes of Venus and Vulcan are very dubious; whence, in the invocations of those deities, they used this formula: Be thou *god*, or *goddess*; as we learn from A. Gellius.

It was a privilege peculiar to *goddesses*, that they might be represented on medals, naked. The imagination, it was supposed, must be awed, and kept from taking liberties, by the consideration of the divine character.

GOD-FATHERS, and GOD-MOTHERS, persons who direct and attend at the baptism of infants; or other persons; and who give the name.

The number of *god-fathers* and *god-mothers* is now reduced to three in the church of England, and two in that of Rome: anciently, they had as many as they pleased.

The Romanists have also *god-fathers* and *god-mothers*, at their confirmation. They even give *god-fathers*, &c. to bells, at their baptism.

Among the ancients it was the custom for persons of quality to have others of like quality cut their children's hair, the first time; by which they became reputed a sort of *god-fathers*: and the like was practised with regard to the hair of the beard.

GOD-FATHER was also a name anciently given to a kind of seconds, who attended and assisted the knights in tournaments, or single combats.

The *god-fathers* of duels were a kind of advocates, who were chosen by the two parties, to represent the reasons of their combat to the judges.

Something of this kind was long retained at solemn carousals. There were two, or more, in each quadrille. See **QUADRILLE**.

The institution of *god-fathers* and *god-mothers*, *patrimi* and *matrimi*, is originally Roman. They are said to have been people, who, in the games of the Circus, attended the chariots, thrives, and images, of the gods. Cicero makes mention of them, in his oration De Haruspicio Respicienda. Their office was much like that of the children in some Romish ceremonies, who are dressed in the habit of angels, to throw flowers, bear incense-pots, lights, &c. and accompany the relics and images of saints.

GOD-GILD, in our Ancient Customs, that which is offered to God, or for his service.

GODSWIT, in Ornithology, the *scolorax agrophala* of Linnaeus, the *agrophala* of other authors, and called also the *varulph* or *varuph*, is a species of birds, taken in the fens, in the same fashion and in the same manner with the ruffs and reeves, and, when fattened, esteemed a great delicacy. This species weighs 12 ounces; the length is fifteen inches; and the breadth twenty-seven; the bill is four inches long; turns up a little, being black at the end and in the upper part of a pale purple; from the bill to the eye is a broad white streak; the feathers of the head, neck and back are of a light reddish brown, marked in the middle with a dusky spot; the belly and vent feathers are white; the tail regularly barred with black and white; the six first quill-feathers are black with their interior edges of a reddish brown; the legs of some are dusky and of others a greyish blue; and the exterior toe is connected as far as the first joint of the middle toe with a strong serrated membrane. The male is distinguished from the female by some black lines on the breast and throat. These birds appear in small flocks on our coast in September, and continue with us the whole winter: they walk on the sands like the curlew; and feed on insects. Pennant.

GOSWIT, red, or *scolorax lobbeana* of Linnaeus, is larger than the former; the bill is somewhat thicker but of the same figure; the lower half is black and the upper yellow; the head, neck, breast, sides, scapulars, and upper part of the back are of a bright ferruginous colour; the head is marked with oblong dusky lines; the neck is plain; the breasts, sides, scapulars, and back varied with transverse black bars, and the edges of the feathers with a pale cineritious brown; the middle of the belly is white, marked sparingly with similar spots; the legs are black and four inches long; and the thighs above the knees are naked for the space of 2½ inch. This is not a very common species in England. Pennant.

GONWIT, *litta*, the totanus of Albinus, is sometimes called the *luna-plum*, and at Venice the *vetoca*.

GOGET, in Ichthyology, a name frequently used for the *gobius niger* of Linnaeus, the sea-gudgeon or rock-fish, and by which it is known in most parts of the world.

This is a long and slender fish, of a rounded not flat body, and seldom exceeds six inches in length. Its colour is very various, being either a brown variegated with white and yellow, or a bluish white with lines of a faint olive-colour, and black spots. The dorsal and anal fins are of a pale blue, the rays being marked with small black spots. The first dorsal fin consists of six rays; the second of fourteen; the pectoral fins of sixteen or seventeen, close-fet together; the middle being the longest and the others on each side gradually shorter. Tab. 17. Fish. N. 8. The belly fins join together into one, and make a sort of funnel-shaped hollow, by which the fish is supposed to apply itself, and stick fast to the rocks, whence it has its name of rock-fish. It is very soft and slippery, yet is covered with scales, but they are very slender and soft. It is caught about the English and Italian shores, and lives in shallow water. It is commonly in the markets of Rome, &c.

GOGGLES, in Surgery, are instruments used for curing squint, &c. or that distortion of the eyes, which occasions this disorder. They are three conical tubes, composed of ivory stained black, with a thin plate of the same ivory fixed in the tubes near their anterior extremities. Through the centre of each of these plates is a small circular hole, about the size of the pupil of the eye, for the transmission of the rays of light. These *goggles* must be continually worn in the day-time, till the muscles of the eye are brought to act regularly and uniformly, so as to direct the pupil first forwards; and by these means the cure will be sooner or later effected. Warner on the Eye, p. 32.

GOHDKADURA, in Botany, a name given by some authors to the tree which produces the *caso casio*.

GOHKATHU, in Botany, a name given by some authors to the tree which produces the gamboge, or *gutta palida* of the Siam.

GOING, in the *Mansing*, called in French *aller*, is the pace or gait of a horse.

GOLD, *aurum*, a yellow metal; the heaviest, purest, most ductile, and shining; and, on those accounts, the most valuable of all metals.

The yellow colour of *gold* is rendered paler by fusion with borax; but this may be prevented or corrected by fusing with nitre, or sal ammoniac. The colour of *gold* is heightened by an alloy of copper, and this property of copper has given rise to sundry processes for exalting the colour of this noble metal. Other metals render it paler. The chemists call *gold*, *fil*, the sun; to denote its pre-eminence over the other metals, which are called by the names of the planets. Its symbol, or character, is O; which, in their hieroglyphical way of writing, denotes perfection, simplicity, solidity, &c.

The weight of *gold* is to that of water, as 19637 to 1000. Fine *gold* immersed in water, weighs near one thirtieth part less than in air, and consequently it is upwards of nineteen times heavier than its own volume of water. The specific gravity of *gold*, or its comparative weight with an equal volume of water has been variously assigned: some have made it 19,637, others, 19,645, and in the Swedish Transactions it is made no less than 20,000; that of water being 1,000. But from the experiments of Mr. Ellicott, it does not appear to have exceeded 19,637; and from those of Dr. Lewis, on the purest *gold*, well hammered, its gravity is stated between 19,200 and 19,400. In all experiments of this kind, the result should be specified with an account of the sensibility of the balance, and the quality and warmth of the water. An increase of heat rarefying water more than it does *gold*, the *gold* must turn out proportionally heavier than an equal volume of the expanded fluid; and this difference is more considerable than it has generally been supposed. From freezing to boiling water, or by an augmentation of heat equivalent to 180° of Fahrenheit's thermometer, Dr. Lewis found that a rod of *gold* was lengthened about one part in 700, and consequently its volume increased about one part in 233, while the volume of water is increased one twenty-sixth or more; hence it appears, that by an augmentation of 40° of the thermometer, or from a little above freezing to the summer heat, the volume of *gold*, if its expansion be uniform, is increased one part in 1048, and that of water one in 117; and the gravity of *gold*, weighed in the water so warmed and expanded, should be greater than when the *gold* and water are 40° colder, in the proportion of about 19,265 to 19,400: and this calculation gives a difference, in the gravity, of 0,034 for every 10° of the thermometer; but some trials seemed to make it greater. It has been imagined, that the comparative gravity of *gold* to brass weights, which are more than double in volume to an equal weight of *gold*, must be so far influenced by the variable gravity of the atmosphere, that there must be an advantage in buying *gold* by weight when the air is lightest. But Dr. Lewis observes, that this difference appears too inconsiderable to be regarded in a commercial way. For the loss of weight of the two metals in the air being as much less than their loss in water as air is lighter than water; and air, as appears from an experiment of Mr. Hawksbee, being in its lightest state about a 937th, and in its heaviest state about an 848th part of the weight of water, it will be found on calculation, that the *gold* preponderates above the brass, in the heaviest more than in the lightest air, only by one part in 14,000, or one grain in about 322 ounces; which is a difference too minute to be sensible in the nicest balance. If the mean gravity of *gold* be reckoned 19,350, as a cubic inch of water weighs about 254 grains, a cubic inch of *gold* will consequently weigh about 4903 grains, or 10 ounces, 103 grains. The pound weight, or twelve ounces, Troy, of *gold*, is divided into twenty-four carats.

The value of *gold* to that of silver, was anciently only as twelve

twelve to one. Indeed, this proportion varies as *gold* is more or less plentiful: for Strabonius relates, that Cæsar brought such a quantity of *gold* from Italy, that the pound of *gold* was only worth seven pence and a half of silver. In our coinage the value of fine *gold* to fine silver is as 15½ to 1. See STANDARD. Sir Isaac Newton observes, in a representation to the lords of the treasury in the year 1717, that in the mints of Spain and Portugal, the value of *gold* is sixteen times that of silver; but that in those countries, payments in silver bearing generally a premium of six per cent. the proportion may be considered as fixed by commerce at 15½ to 1; that in the other parts of Europe, the value of *gold* is at most fifteen, and in China and Japan but nine or ten times that of silver; so that *gold* is rated higher in England than in any other part of Europe, and higher in Europe than in the Eastern countries. Hence, in great measure, arise the profits of exchanging *gold* for silver in one place, and re-exchanging them in another: and hence the greater disparity between the relative quantities of *gold* and silver in one commercial nation than in another; this metal being brought in most abundance which is rated highest in proportion to the other, and that which is rated lowest being drained away. There are various ways of determining the fineness of *gold*; or the proportion of alloy which it contains. Those who are skilful in this business can judge nearly the proportion of alloy from the colour of any given mass, provided that the species of alloy be known. For the method of doing this, see TOUCH-STONES. The great excess of the weight of *gold*, above that of the metals used for its alloy, affords another method of determining the quantity of alloy in any given mass, where the species of alloy is known. Thus fine *gold* loses in water one grain in every 10,3 nearly; and fine silver loses one grain in about eleven; from whence it is easy to find the loss of any number of grains of each, and consequently of any assignable mixture of the two metals. Thus, fifty grains of *gold* will lose above 2½, and fifty grains of silver somewhat more than 4½; so that a mixture of equal parts of the two will lose above seven in a hundred, or one in fourteen. A mixture of *gold* with half its weight of silver will lose one part in 15½; with a third of silver one in 16½, with a fourth, one in 16½; and with an eleventh of silver, which is the standard proportion of alloy, one in 18½. On this principle, the specific gravity, or proportional loss in water, of *gold* alloyed with different quantities of silver, copper, and mixtures of both, may be computed and formed into tables for use. The accuracy of this method, it should be observed, depends on the supposition, that each of the two metals, that are melted together, retains its own proper gravity, which is the case in mixtures of *gold* and silver; but *gold* and copper, melted together, are specifically lighter than if they were weighed separately; and this also is the case of mixtures of *gold* with zinc, tin, iron, and platinum; but the reverse happens in mixtures of it with lead and bismuth. It appears, therefore, that the hydrostatic balance cannot discover, with certainty, the exact fineness of *gold*, unless when silver is the metal mixed with it.

GOLD, alchemical history of. See PHILOSOPHER'S STONE, and TRANSMUTATION.

GOLD, chemical history of. The first characteristic or property of *gold* is, that it is the heaviest of all bodies; so that whoever would make *gold*, must be able to add the weight of other matters, and make them equiponderate with *gold*.

In every mass of matter, therefore, heavier than mercury, there must necessarily be a share of *gold*, there being no body in nature, known till of late years, of intermediate gravity; i. e. no body whose gravity is to that of *gold*, more than as fourteen to nineteen.

The discovery of the ponderous metal PLATINA has now afforded an exception to this long received axiom, and shews that weight alone is no criterion of *gold*; for pure platina, perfectly void of *gold*, is nearly as ponderous as *gold* itself.

Its second character is, that of all known bodies it is the most ductile and malleable, and of all bodies its parts have the greatest degree of attraction, i. e. they cohere with the greatest force. Our gold-beaters and wire-drawers furnish us with proofs of this property. They every day reduce *gold* into leaves or lamellæ, inconceivably thin; yet without leaving the least aperture, or chasm, visible to the best microscope, or even pervious to the light. See this property considered more at large under the article DUCTILITY.

The tenacity of the parts of *gold* is also much greater than that of any other metal, for five hundred pounds can be supported by a wire of one-tenth of an inch in diameter made of *gold*, but not of any other metal. The malleability of *gold* is very little affected by a mixture of silver; it is not much diminished by copper, which ren-

ders it harder than silver does; and next to these two metals, platina injures its malleability the least. But all the rest of the metallic bodies render it brittle in different degrees; and its malleability is destroyed by fumes of lead, and of most other metallic substances, but may be recovered by fusion with nitre. It has been said by many that this property of *gold* is injured by the fumes of charcoal; but Dr. Lewis believes this to be a mistake. The malleability of *gold* is also diminished by cooling it, in a state of fusion, too hastily; for preventing which, artists heat the mould into which the *gold* is to be cast. Mr. Boyle mentions an anti-elixir, which he tried; that is, one that would debate *gold*, and which changed its malleability, colour, homogeneity, and specific gravity; so that though the powder did not weigh the thousandth part of the *gold*, yet the specific gravity of the metal to which it was debased, was to that of water but as 15½ to 1, instead of 19 to 1. Boyle's Works abr. vol. 1. p. 78. It is observed by Dr. Lewis, that, though the expansion of *gold* is less than that of other metallic substances with small degrees of heat, it nevertheless expands more than most of the other metals, when fused; and as it thus shrinks more, when it becomes solid, it is less capable of receiving sharp and perfect figures, when cast into moulds, than silver, copper, lead, and tin, which do not shrink so much, and much less than iron and bismuth, which expand in passing from a fluid to a solid state. *Gold*, when melted with a low white heat, has a bright bluish green colour.

It is the received opinion, that whatever has been done to this metal, the common way of purifying it by the copel restores it easily to itself again; but this is not always so certain, or so easily as it generally imagined. Mr. Homberg put into the copel an ounce of *gold*, which he had used in several chemical experiments, in order to restore it to its original state; but after four times compelling it, he found, that whatever quantity of lead he used, still the metal, though of the right and beautiful colour, was brittle, and not at all in the ductile state of pure *gold*. Finding, therefore, that lead would not answer his purpose, he incorporated the *gold* with four times its quantity of silver; and having performed the operation of the depart in the common manner, he fused it with borax; but after all this the *gold* was as brittle as before, though still of the same beautiful colour. He then melted it again without any addition, but still it remained in the same brittle state. His next trial was by antimony, not doubting but that the particles, whatever they were, that had stood the operation of the depart, and of lead, would be absorbed by this powerful semi-metal, and the *gold* left in its natural malleable state. He melted it twice to this purpose with eight ounces of antimony; but after separating the antimony, and then melting the *gold* several times with salt-petre, and many times without any mixture, it was found of the most perfect and beautiful colour imaginable, but still brittle, and not in the least malleable. Surprised to see all the common methods fail, he melted it again with six ounces of antimony, and afterwards melted this regulus with three times its own weight of lead, and set the whole in a copel in a proper degree of fire, to evaporate both the antimony and the lead. But when the fire was out, he was surprised to find the *gold* covered with a brownish substance, resembling a mushroom, which fell to powder on being touched by the fingers. The *gold* itself was become of a grey colour, and was full of wrinkles on the upper surface, from whence this fungous matter had been thrown out; but on the under surface, where it stuck to the copel, it was still of a fine and beautiful *gold* colour. He then melted several times the *gold* and the fungous substance together, and every time there appeared the same sort of fungous crust at the top. At last he gathered this fungous substance carefully off from the *gold*, and then melting the metal by itself, there was no more any fungous matter thrown out upon it, but only a thin layer of a powder of the same nature and colour with the former. Three times it was melted, and at every time threw off a quantity of this powder; and after this, being fused with borax, it at length became perfect malleable *gold*. He then fused together the fungous matter, and all the quantities of powder which he had saved, there appeared a new fungus on the matter, and that for several times melting; but at last this disappeared, and there was found a small lump of pure *gold* in the copel. It is not easy to guess at the cause of this obstinate brittleness of the *gold*, because it had passed several experiments, and been mixed with several salts and several metals, particularly at last with iron and with emery. The emery seemed most to be suspected of the cause; but this itself cannot be given to *gold* by emery alone, and must have been owing to the mixed effect of some of the salts and emery together, as by means of the salts, the particles

of emery are thrown farther, and more intimately mixed with those of the *gold* than they could otherwise be. We have been told of the degradation of *gold*. This *gold* would have been declared degraded, and robbed of one of its greatest qualities, its malleability, had it fallen into any hands but those of so great a chemist; and it is much to be doubted, whether Mr. Homberg would not have been able to reduce the degraded *gold* of any other chemist, and restore it to its natural state and purity, though the common methods of operating on it should all have failed, as they did in this case. Mem. Acad. Par. 1693. The third character of *gold* is its fixeness in the fire; in which it exceeds all other bodies. This property seems to result from the homogeneity and equality of its parts, which equally aid and support each other, and have equal pores, or interstices, through which the fiery corporeals find an easy passage. The prince of Mirandola, Mr. Boyle, and most other chemists, furnish divers experiments to illustrate this wonderful fact. After laying a quantity of *gold* two months in the intensest heat imaginable, it is taken out without any sensible diminution of weight; whereas the other metals, platinum and silver excepted, are soon deprived by fire of their metallic appearance, and either dissolved in flames, or changed into an earthy or glassy form.

It must be added, however, that in the foci of the large *air-bath* of M. Tschirnhausen and Villeta, even *gold* itself volatilizes and evaporates. After this manner, we are told from the Royal Academy at Paris, a quantity of pure *gold* was vitrified; being first fused in a sort of calx, which emitted fumes, and lost of its weight. But the same calx, fused again with a quantity of grease, was restored into *gold*.

Mr. Homberg found by experiment, that *gold* properly managed in the focus of the great burning glass, after the evaporation of some of its constituent parts, was vitrifiable, like other metals. That part of this metal which flies off in fumes, he says, is the mercury which entered its composition, and what then remains, which is an earth penetrated by sulphur, runs into glass, as all other substances of a like kind must with a like fire. But he ought to have previously ascertained the purity of the *gold* which he employed; for want of which the glass produced in this experiment might proceed from copper, or other metal, with which the *gold* might have been alloyed. Besides, as the substances exposed to the focus of the burning glass are laid upon a piece of charcoal, and that charcoal is always in part reduced to ashes about the body in trial, and these ashes often fly over and all about it; it was objected to Mr. Homberg, by some who saw his experiments, that these ashes alone vitrified on the *gold*, and not any part of the *gold* itself; but Mr. Homberg replies, that if this were the case, these ashes would also be vitrified upon silver in the like trials and circumstances, and give an appearance of the silver's vitrifying; but often repeated experiments have proved, that silver exposed to the focus of the burning glass, gives not the least sign of vitrification in any circumstance, unless it has been refined with antimony; that is to say, unless there has been given to it by air more sulphur than it is naturally possessed of; but in that case, these unnatural abundant sulphurs will always vitrify a part of its earth. Mem. Acad. Par. 1702. 1707.

With regard to this experiment, Dr. Lewis observes, that the ashes might casually have been accumulated on the metal, so as to produce a sensible vitrification, in one instance, without being so in another, and that, at best, it is too imperfect for any trials at all to be laid upon it. The same experiment has been repeated by others without success, and though the *gold*, exposed to the focus of a burning lens, does really decrease in weight, this diminution appeared to be owing to the separation of minute globules in substance, which were found to be perfectly unchanged *gold*. The true alchemists have made no doubt of the possibility of decomposing, or entirely destroying *gold*, and of transmuting the baser metals into this; their books are filled with various processes for these purposes notwithstanding which, the producibility and destructibility of *gold* still continue problems in chemistry; nor is there any experiment from which the possibility of either can be inferred; though there is reason to believe, that its resistance to all our operations is owing to our inability to raise a sufficient heat.

Its fourth character is, that it is not only unalterable by air and water, but that it resists, while its aggregation is entire, the action of the strongest simple chemical menstrua, either in the dry or humid way. It is said not to be soluble by the strongest mineral acids, when they are pure, nor by sulphur, nor by alkalis. However, though it has been generally supposed by the assayer and refiner, that *gold* is absolutely indissoluble by the nitrous acid; yet Dr. Brandt has lately published, in the Swedish

Transactions for the year 1748, a discovery of certain circumstances, in which *gold* is dissolved by this acid in considerable quantity. For, having boiled a mixture of *gold* and silver, amounting to about fifteen pounds, in which the proportion of the silver, containing a little copper, to the *gold*, was as 16 to 3, with fresh portions of stronger and stronger aqua fortis, in a glass body, to which was fixed a head and recipient for collecting the acid vapours that arose; he poured off the solution from the *gold* when all the silver and copper were nearly dissolved, and boiled down the next portion of aqua fortis, till the matter at the bottom appeared like a dry salt. He then added more aqua fortis, which, after boiling for some time, appeared yellow, and was poured off into a separate glass; this yellow aqua fortis he afterwards used for dissolving some silver, and found a considerable quantity of *gold* at the bottom of the glass, though the silver had been very carefully purified from *gold*. In this experiment, pure silver, which exhibited no appearance of *gold* with common aqua fortis, precipitated from the yellow aqua fortis a spongy lump of *gold*. In keeping a part of the *gold* separated spontaneously in form of a brown powder; after it had been long kept, and deposited much of its *gold*, it was found on an assay to contain more *gold* than silver, in the proportion of 19 to 12. In this state, a quantity of it, sufficient to dissolve four parts of silver, yielded during the dissolution one part of *gold*; so that the nitrous acid is capable of dissolving above one fourth part as much *gold* as of silver. This experiment shews a necessary and useful caution to those that are concerned in the parting of *gold* and silver by aqua fortis.

Gold is said to be dissolved by several compound menstrua: as, by the marine acid mixed with a small proportion of spirit of urine; by a mixture of the vitriolic acid with the same urinous spirit; by a mixture of the vitriolic acid with a little fixt alkaline salt; by the vapour which arises during the effervescence of the vitriolic acid with fixt alkaline salt, collected by distillation; by a spirit, prepared by saturating the vitriolic acid with volatile alkaline salt, exsiccating the mixture, dissolving it in twice or thrice its quantity of aqua fortis, and distilling the solution. But Dr. Lewis could not discover, in any of his experiments, that any of these liquors had any action on *gold*. But the most effectual menstruum of *gold* is aqua regia, which, in a moderate heat, readily and totally dissolves it into a transparent yellow liquor, and, therefore, serves to separate *gold* from silver. Another solvent of *gold* is a combination of sulphur with fixed alkali, called liver of sulphur. See REFINING.

Nevertheless, though a mass of *gold* resists the action of simple solvents, we must not conclude, that it is absolutely incapable of solution by any of them. An instance to the contrary has been already produced; and Mr. Margraaf has discovered, that this metal, precipitated by an alkali from its solution in aqua regia, is then rendered soluble by any, even of the vegetable acids. See MERCURY and SILVER.

Besides, *gold* dissolved in aqua regia is not precipitated, when the proportions of the two acids of this compound menstruum are changed, by adding to this solution any quantity of urinous or marine acid. Further, *gold* may be dissolved in alkali, by the process of the martial alkaline tincture of Stahl; that is, by pouring into a concentrated solution of fixed alkali in water, a small quantity of solution of *gold* in aqua regia, in which the acids are not too much saturated, the *gold* will be quickly seized and dissolved by the alkali.

A solution of *gold* in aqua regia affords a very curious object for the microscope. Mr. Leewenhoek took great pains to observe the configurations it must put on in its concretions; he found, that in warm weather, if a drop of the solution was laid on a clean glass, and examined by the microscope, the salts soon coagulated, but appeared very irregular in their manner of concretion. They sometimes assumed a regular hexangular form, but more frequently they were rendered irregular, by the application of other substances, in form of smaller crystals upon them. One thing in this is very remarkable, that is, the crystals formed at different times seem very differently impregnated with the metal, those which concrete first being usually large, and perfectly clear and transparent, and those which afterwards form themselves upon these and alter and injure their figures, being smaller and seemingly much more impregnated with the metal, as being all of a fine *gold*-yellow. Sometimes also it happens, that the small salts faced with the particles of the *gold* shoot first, and when the other clear and transparent crystals of salt form themselves afterwards, it not infrequently happens that they form about the others, and inclose them within their own bodies. Thus it is not uncommon to see one of these large and transparent crystals

crystals with a small gold-coloured crystal immersed in its centre.

This is a very elegant and entertaining sight by the microscope, but it is only to be observed in dry seasons, for in moist weather the crystals either do not form themselves at all, or else it is done but very confusely, and they melt and dissolve away on the access of fresh damp air.

If a small piece of copper be put into this solution of gold in aqua regia, the liquor immediately operates upon it and not only dissolves the copper, but precipitates the gold it had before held in a state of solution upon the surface of the copper, in the place of which copper it had taken away. The same thing happens when a piece of copper is put into a solution of silver in aqua fortis, but in this last case the effect is more beautiful; for the silver particles precipitated on the copper arrange themselves in the form of trees and shrubs, like the *Azoreum Diumi*; but in the case before us, the gold is only precipitated in form of irregular filaments, or small granules, and seems rather to imitate that process observed in the famous water of the Ziment, or Cement Springs in Hungary, where the water being highly impregnated with a solution of blue vitriol, containing a very large portion of copper, if a piece of iron be put into it, immediately it works upon the iron, and dissolving it, precipitates copper in small irregular granules in its place; for that, in the opinion of the vulgar, the copper is made of the iron, but in reality the iron is all dissolved, and the copper left in a solid form by the menstruum which dissolved it; as in this experiment, the copper put into the solution of gold is dissolved, and taken up into the liquor, and the gold which was before dissolved is precipitated in its place.

If the assistance of art be called in, and the solution of gold be made according to the rules of chemistry in a sand heat, and the menstruum is fitted with it, that it can dissolve no more, then it readily throws into crystals, on being exposed to dry in drops before the microscope on plates of glass; and the crystals which it forms are in this case all of one kind, all fitted with gold, of a regularly regular figure, and their angles very sharp.

These crystals appear only like to many pieces of pure gold, of a fine lustre and brightness, and seem mixtures of native gold, of this form just taken from some mine. In order to procure these gold crystals as regularly formed as can be, the small drop, laid on the plate of glass, must be poured off again at one side, and by this means the liquor being spread extremely thin, the crystals will be formed extremely regular; but then they will be so small, that they are only visible through very powerful glasses; when thus managed, however, they show their true form, which is regularly hexagonal, but that not in form of a column, as in the hexagonal crystals, but in a flat and thick mass, resembling a die, only more long-shaped, not so exactly square. Notwithstanding that these small crystals are yellow, they are as transparent as crystals, and the liquor remaining about them is also yellow and transparent. Some of these crystals, though of the same figure with the others, appear not of the same even and plain structure, but are plainly seen to be formed of a great number of rings, or concentric circles, extended round each other. Copper being put into this solution, so highly saturated with gold, is not preyed upon so fast as in a weaker solution; some few air-bubbles, however, are driven to the surface, but without any great effect, but if the solution be diluted with a little water, the acid then preys with violence upon a piece of copper put into it. A part of the copper is soon dissolved, and the liquor becomes green, and a small portion of the gold, out of the solution, is precipitated on the copper, in the place of that part of it which was dissolved. In this case also the gold, in some measure, emulates the appearance of the silver in its conversion; for though it does not form regular trees and branches, it forms long and slender filaments, and these do not look of a pure fine yellow, or like pure gold, but seem dusky, and to have some copper among them.

If a small parcel of this solution be evaporated on a glass plate over a gentle heat, the nature of the metal, and its effects on vitrified bodies, are more easily discovered than one would expect in such small quantities. Where the liquor has lain the thickest in this case, the glass is tinged red by the entrance of the particles of gold into its surface, which they do easily; because in those places where the liquor lay thin, they formed themselves into extremely minute concretions, according to the foregoing observations, and it is well known, that red is the colour which gold imparts in the earth to crystals and other bones, and in the experiments of the chemists, to glass of any kind. In such places as the liquor has lain thicker in, and has been consequently evaporated in larger quantity, and from

a larger portion of the gold, the glass is not tinged red, but there is seen a remainder of the solution sticking to it; this, however, is not turned into crystals, but is in this case pure gold, left from the evaporation in its proper metallic form. This, however, was in such minute concretions, that where they lay single, or separate, they were not visible, according to Mr. Leewenhook's account, to the naked eye, and he computes that many thousands of millions of them were not equal in size to a single grain of sand; in most places they were not, however, thus separate, but were formed into oblong and slender concretions, which were sometimes simple, and sometimes ramose, and the microscope shows these concretions very elegantly, some in form of simple threads, some of branches of trees or plants.

The density of gold is no way better seen than in this experiment; for though it may easily be conceived, that such particles of this as were but of a thousand-millionth part, or much less than that, of the bigness of a grain of sand, small needs be, of an almost inconceivable thinness, yet not the smallest of these would manifest any light through it, but all were as perfectly opaque as a piece of sheet lead. A small drop of a solution of gold in aqua regia being laid over a strong fire, approaching it by degrees, till being exposed to its utmost heat, both the gold, and the glass on which it lies, begin to melt; in this case the gold is found concentered in the manner into filaments composed of globules, or of particles nearly round; and it is taken from the fire just at that time, when the glass only begins to run, in order to the microscope a very distinct way of observing the ramifications of the gold and silver-ores in their first state, and shows how they are formed. Phil. Trans. N° 286.

Solutions of gold in the pure marine acid, and in mixtures of the pure acids of nitre and sea salt, are not made to crystallize without great difficulty; in order to which, the liquor should be evaporated, till only about one half of it remains, and then let by in the cold, with the addition of a few drops of pure spirit of wine. The crystals obtained from high-coloured saturated solutions are generally of a red colour, and sometimes, as it has been said, of a deep ruby red. If any light essential oil be poured upon a solution of gold in aqua regia, and the mixture be shook, the gold will pass into the only matter, float with it upon the surface, and be kept for a little time dissolved by its the metal, however, will gradually separate, and be thrown off to the sides in bright yellow fims, which on shaking the vessel fall to the bottom. ETHER, poured on in the same manner, will float difficult on the surface, become yellow by imbibing the gold, as the yellow tinge of the acid diminishes, keep it permanently dissolved, and, when loaded with the ponderous metal, continue till to float upon the acid; and, as gold is the only one of the known metals, which has ether taken up from acids, this fluid affords a ready method of distinguishing gold contained in acid solutions. See AURUM PRÆPARATIO.

Liquors containing a grosser inflammable matter, as wine, vinegar, solution of tartar, are likewise found to extricate gold from aqua regia in its metallic form; but with this difference from the preceding, that the gold, instead of floating on the surface, falls generally to the bottom. Gold may be precipitated from solutions in aqua regia by adding the solution of any fixt alkaline salt, or a volatile alkaline spirit, in sufficient quantity to saturate the acid; the mixture will become turbid, and after standing for some hours, the gold will fall to the bottom, in form of a brownish yellow muddy substance, retaining some of the saline matter. To accelerate the precipitation, the solution should be diluted with three or four times its quantity of water, or more; and the alkaline liquor should be added gradually, and in small quantities. If the aqua regia has been prepared with sal ammoniac, or if the precipitation is performed with a volatile alkali, we shall have the *flaming gold*, or *AURUM FLAMMANS*. Farther, all the metallic bodies that dissolve in aqua regia, platinum excepted, precipitate gold from it. Some of them precipitate it also, when they are previously dissolved in other acids, and even in aqua regia itself. The precipitate occasioned by adding tin is the most remarkable of these. A plate of pure tin, put into a solution of gold largely diluted with water, changes the yellow colour of the liquor into beautiful purple or red; and, by degrees, a powder of the same colour slowly subsides, and leaves the menstruum colourless. Solutions of tin, made in aqua regia, have the same effect with tin itself, with regard both to the precipitation and the colour; and hence characters, drawn on paper with a diluted solution of gold, not visible when dry, become immediately red or purple on passing over them a diluted solution of tin. On dropping a solution of silver into a solution of gold, both metals precipitate; the same double precipitation happens,

happens, on mixing solution of *gold* with solution of lead in aqua fortis. Pure sulphur has no action on *gold*. See *REFINING*. However, it unites perfectly, as we have already observed, with the *hepar sulphuris*, or liver of sulphur. The addition of any acid to this solution, absorbing the alkaline salt, precipitates the *gold* united with the sulphur; and the sulphur may be separated by fire, or more readily separated, by adding a little copper for absorbing the sulphur. Copper and iron likewise added to the mixture of *gold* and *hepar* in fusion, will precipitate the *gold*, and unite with the sulphur.

The fifth character of *gold* is, that it readily and spontaneously, as by some magnetic virtue, attracts and absorbs mercury, though what Lord Bacon writes, viz. that *gold*, in imbuing mercury, increases in specific gravity, we doubt, is but ill warranted. It is more than probable it must be increased in bulk, more than in weight, and consequently must be specifically lighter.

It may be added, that as soon as the mercury enters the *gold*, the metal becomes soft, like a paste. See *AMALGAMATION OF GOLD*, and *GILDING*.

The sixth character is, that it withstands the violence both of lead and antimony, i. e. being fused in the copel along with either of those matters, it does not dissipate and fly off with them in fume, but remains fixed and unchanged.

All other metals, except *gold* and silver, melted with lead, perish with it, and evaporate by fire; and in antimony, all other metals, except *gold*, even silver itself, undergo the same fate. Thus, if a mass consisting of *gold*, silver, tin, copper, &c. be fused together with antimony, the several matters become separated, and all but the *gold* rises to the surface in form of a scoria, and is blown off with bellows; but the *gold* remains behind, much purified, as having lost all its heterogeneous parts along with the other metals. And hence antimony is used as the test of *gold*. See *REFINING*.

The seventh character is, that of all bodies it is the simplest (the primary elements being excepted). By simple we here mean that whose minutest part has all the physical properties of the whole mass. Thus, if a grain of *gold* be dissolved in aqua regia, and a single drop of the solution be taken, a quantity of *gold* may be separated therefrom, which shall only be the millionth part of the grain, and yet still have all the characters of *gold*. Or if you fuse a grain of *gold* with a large mass of silver, and mix the two together, so that the *gold* becomes equally diffused through the whole mass, you will have in every particle of the mass a particle of perfect *gold*. Accordingly, dissolve any part of this mixture in aqua fortis, and a quantity of *gold* will precipitate to the bottom, bearing the same proportion, as some have supposed, to the grain that the part dissolved did to the whole mass. On which principle depends the art of *ASSAYING*.

But this does not appear to be strictly true: for, in many cases, there is a sensible inequality in the distribution of the *gold*. M. Hellot melted upwards of twenty pounds of silver, containing about a fifty-sixth part of *gold*, in a crucible, and poured it into cold water, in order to reduce it into grains; and by dipping at different times an iron ladle into the water, under the stream of metal, he received a part of the first running, a part of the middle and a part of the last; the three parcels, assayed separately, were all found to differ with regard to the quantity of *gold* contained in them.

GOLD, history of. All the known parts of the earth afford this precious metal; though with great difference, in point of purity and abundance. Europe, so fertile in other respects, comes forth of all other quarters in *gold*. The most considerable mines in this quarter of the globe are those of the Upper Hungary; and particularly that of Cserniz, which has continued to yield *gold* for ten centuries. America furnishes the most; and particularly the mines of Peru, Mexico, and Chili, and other provinces of the Spanish West Indies; to which may be added the Brazil, belonging to the king of Portugal.

In many parts of Asia, particularly Sumatra, Pegu, China and Japan, the Philippine Islands, and Borneo, *gold* is found in considerable quantities. At Canton, the *gold* is cast into discs of about ten tale weight, or twelve ounces two penny-weights four grains, of an equal fineness: these discs are bigger at both their ends than in the middle, formed with their brims rising above the rest; so that the upper side somewhat resembles a boat; from the middle, which, in cooling, sinks into a small pit, arise circles one within another; and the smaller and closer these are, the finer the *gold* is. *Gold* in bars or ingots comes chiefly from Cochinchina and Tonquin: the discs and bars are very often debased and gilt. By the laws of China, *gold* is forbidden to be exported.

The coast and interior parts of Africa likewise afford great quantities of this precious metal. Some *gold* has

been discovered in Brazil, at different times, though hitherto in small quantities. It is chiefly found in that kind of tin-ore called the stream tin.

Glauber, an eminent chemist, asserts, that there is not any sand or stone, but *gold* may be procured from, limestone only excepted: the misfortune is, that the expense of separating it much surpasses the profit.

Many of the common sands, particularly the yellow, red, black, and those inclining to a violet colour, appear to be rich in *gold*. Becher and Cramer profess, that there is no sand in nature entirely free from it; Becher undertook to separate it with profit from the common sea-sands, and entered into engagement with the States of Holland for establishing a mineral work on this foundation; but the issue, though favourable, does not appear to have been sufficiently lucrative; for the scheme was never prosecuted.

Gold is chiefly found in mines; though there is some also found in the sand and mud of rivers and torrents; particularly in Guinea. This bit is in form of a fine dust, and is called *assay-gold dust*. From Cape Coast, on the coast of Guinea, we receive yearly between two and three thousand ounces of the dust; and three or four hundred ounces are said to be collected yearly from the sands of the Gambia, and cast into bars at Jamesfort, one of our settlements on this river. The *gold* dust from Africa, in its purest state, is said to be from twenty-one to upwards of twenty-two carats fine; but the natives frequently mix with it filings of brass. However, this adulteration may be easily detected by the hydrostatic balance, or by pouring on the mixture a small quantity of aqua fortis, which will receive a blue tincture from the copper in the brass.

There are many European rivers, which roll particles of *gold* in their sand; from collecting which the neighbouring inhabitants derive some advantage: such are the Rhine, the Rhone, the Garonne, the Danube, the Elbe, &c. and the Schwarz, in Upper Saxony, is said to be rich in this metal, and its sand to be worked with great profit. The *gold* is found most plentifully in these rivers, where their course is slow and uninterrupted, where the sand is reddish or blackish, which, being more ponderous than the white sand, determines the particles of *gold* to settle with it, and when the water has subsided after a flood.

Glauber tells us, that there is a third sort of *gold*, scarce found any where but in the strata of the mountains of Chili, which they separate from the earth by washing; whence the places where it is found, or separated, are called *lavaderos*.

This earth is usually reddish, and very fine: at about six feet deep it is mixed with grains of large dust, and from hence commences the stream, or bed of *gold*. Between are banks of soft bluish stone, mixed with yellow strata, which yet are not *gold*, but only pyrites, or marcasite of *gold*.

When they have discovered any of this earth, they endeavour to bring rivulets to it (which in these mountains are very frequent) in order, by force thereof, to tear off the upper earth, and lay the golden stratum bare. This they forward by loosening it, and digging with spades, &c. As soon as the golden earth is uncovered, they turn off the water, and dig up the soil by force of arm; and loading it on mules, carry it to the *lavaderos*, i. e. a sort of basins of water, where the earth undergoing divers repeated lotions, in different waters, the earth and impure part is all separated and carried off by the stream, and the *gold* left at bottom. This method of getting *gold* is immensely gainful; the expenses being but trifling, compared with those attending in the common way by machines, fire, and quicksilver: the richest of these *lavaderos* is that de El Estanco del Rey, twelve leagues from the Concepcion, a part of the South Sea. Thuringia, and some other places along the Rhine, are the only places in Europe where *gold* is got in this manner.

The way of separating it thus: they have a long trough made with a declivity, and lined in the bottom with hamel, or coarse cloth; the sand is received into this, and while it is stirred about in the water by the hand, the sand is washed off, and the small particles of *gold* left in the pores, and among the woolly matter of the hamel, which is afterwards washed out from thence. The *gold* is afterwards extracted from the remaining matter by mercury.

This is the method where the sand is fine; but when it is mixed with large gravel, they sift it through wire sieves, whose meshes are of one determinate size, or a kind of basket made of rods, placed at the upper end of the trough; by which means all the *gold* is said to go through with the sand, and the gravel or larger stones are left behind, and thrown away. The sand thus separated is treated as before; and there is no danger of any *gold* being

being thrown away with the gravel, because it is extremely rare to meet with any one grain of gold in this state so large as a barley-corn; and therefore as the meshes of their sieves are kept to more than that size there is no fear of losing any of the metal.

The gold of mines is of two kinds; the one in small pieces, or grains, of different forms and weights. Of this sort, among the specimens sent by Columbus into Spain, to let them see the richness of his discovery, there were some of eighteen ounces weight; and the relations of those days assure us, that in 1502 there were others found of thirty-two pounds weight.

Reaumur reports, that a piece was shown to the French academy, which weighed four hundred and forty-eight ounces; and another, in the cabinet of Antonio Pericazero, weighed upwards of five hundred and twenty-eight ounces; both which pieces, on being assayed, were found to be of different fineness in different parts of the mass. However, it is rare to meet with masses of the weight even of an ounce: the largest in the British Museum weighs but fifteen penny-weights.

The other kind of gold is dug up in the stony gables, which are what they call the *mineral ore of gold*: these gables are of various colours, and are usually one hundred and fifty, or one hundred and fifty fathom deep. They strike fire with steel, and are not fusible in aqua fortis. Along with the gold they usually contain some other mineral and metallic matter, particularly silver, without some share of which it is scarce ever found.

The quantity of gold, in proportion to the earthy and stony matter mixed with it, appears to be in general exceedingly small. Voyagers of credit relate, that the common yield is no more than five or six ounces of gold upon the casso, or fifty hundred pounds of the mineral.

GOLD, manner of separating. They first break the metalline stone with iron mallets, pretty small; then carry it to the mills, where it is ground into a very fine powder; and lastly pass it through several brass-wire sieves one after another, the last is fine as any of our silk sieves.

The powder thus prepared is laid in wooden troughs, and soaked for some time in a solution of common salt; the proper quantity of mercury is then squeezed in through a linen cloth, so as to fall like a dew over the surface; and the mixture being well stirred and kneaded, the gold is incorporated, with the application of a gentle heat, in five or six days. After this the water, with the recalcitrant earth, is driven out of the tubs by means of other hot waters poured thereon. This done, there remains nothing but a mass of mercury with all the gold that was in the ore. The mercury they separate from it by distillation in large alembics. The gold, in this state, is called *virgin gold*; as well as that found in the sand of rivers, or that in grains in the mines, because none of them have passed the fire. After this they usually fuse it in crucibles, and cast it into plates, or ingots.

The method of working this ore at Chrennitz in Hungary, does not differ much from that already described, and it is as follows: they wash the powdered ore very often, and lay it in powder upon cloths, and by the gentle and oblique descent of the water over it, and their continual stirring of it, the earthy, clayish, and lighter parts are all clean washed away, while the heavier and metalline remain in the cloth. Not much unlike to this proceeding is that with sheep's skins and wool, which they place either in the water that comes from the works, or in the streams of rivulets, which have their origin in hills where there is much gold; so that while the water or fluid part pass through, or over them, the more solid, heavy, and metalline are infused and detained, and by this means the skin becomes a golden-sieve. The cloths which are by the Chrennitz-works in this manner impregnated with gold, are washed in large tubs of water, and after sending the water is decanted slowly off; the sediment which is left behind is, after this, washed in three or four other waters, and to the clean remainder they add quicksilver, which they then work and knead into an amalgam, like dough or paste. When they have worked this together for an hour or two, they throw it into water, and wash off the quicksilver, which did not adhere, and then there remains a pure and perfect mass of the amalgam. They squeeze as much of the quicksilver as they can from this, first through coarse cloths and then through fine ones; they then put the remainder on a perforated plate, which they place over a deep pan, set in the earth, in the bottom of which there is put some quicksilver; they then cover with a hollow earthen-dish, luting it carefully on, and when the lute is dry they make a charcoal fire over it. By this means the quicksilver yet remaining with the gold in the amalgam is driven off, and runs down through the holes of the plate, mixing itself with the rest in the bottom of the pan, and the gold is left alone in a spongy mass, which only needs once melting in the common

way to be pure and malleable gold. Brown's Travels, p. 67. See other processes described under the article AMALGAMATION of gold.

When the gold is intimately combined in the composition of ferruginous sands, the sand should be made red hot, and quenched in water, and the ignition and extinction repeated four times or oftener. Mix the sandy thus calcined, with twice its weight of granulated lead, and its own weight of black flux, consisting of one part of nitre, and two or three of tartar, mixed and burnt in a covered vessel to a black alkaline coal, and then put the mixture into a crucible, and cover it with sea-salt dried over the fire till it has ceased to crackle. Expole the crucible in a blast-furnace to a strong fire, and stir the matter occasionally with an iron rod; when the scoria is become thin as water, which is known by the rod's coming out almost clean, let the crucible be left to cool; and the gold contained in the sand will be transferred to the lead, and may be separated from it with a cupel or test. The silver contained in these sands, may be separated from the gold, after cupellation, either by aqua regia or aqua fortis. Instead of the black flux, four parts of pot-ash, and three of powdered charcoal, will answer the purpose when applied to thirty-two parts of lead, and sixteen of the calcined sand. Or, the calcined sand may be boiled in melted lead, without any inflammable or saline addition. When gold is intimately combined with other metals in their ores, the ore is to be run down in the same manner as the same kind of ore without gold; and the gold may be afterwards separated by different processes, according to the nature of the metal.

There are various methods of separating gold from silver works: it may be separated from the surface of silver, either by spreading over the gilt silver a paste made of powdered sal ammoniac moistened with aqua fortis, and heating it till the matter smokes, and is nearly dry; throw it into water, and the gold will easily come off by rubbing it with a scratch brush; or, by putting the gilt silver into common aqua regia, nearly boiling and turning the metal frequently, till it becomes all over black; then wash it with water and rub it with the scratch brush, which will disengage the gold left by the aqua regia. See GILDING.

Gold may be separated from gilt copper, by applying a solution of borax to the gilt parts with a pencil, and sprinkling over the place thus moistened, a little powdered sulphur; when the piece is made red-hot, and quenched in water, the gold may be wiped off with a brush.

Gold may be recovered from wool, gilt on a water fire, by keeping it for a quarter of an hour, in a quantity of very hot water, sufficient to cover it; then scrub the wool in a little warm water, with short stiff brittle brushes of different sizes: boil the whole mixture of water, fire, gold, &c. to dryness; make the dry matter red hot in a crucible to burn off the size, and grind the remainder with mercury. The gold will be more easily laid hold of by the mercury, by the addition of fume clean fluid.

GOLD, manner of assaying. This is performed with the touch-stone, and touch-stones, but more securely by fire; which latter method consists of two processes; the one for separating gold from silver by aqua fortis, and the other from base metals, by keeping the mix infusion for some time upon a cupel or coffee, with the addition of lead. See ASSAYING.

GOLD, manner of refining. There are three principal methods of refining gold; the first with antimony; the second with sublimate; and the third with aqua fortis. This last method is called *deputing*, or *parting*. See DEPARTING, and QUANTIFICATION.

For the two former, see REFINING. There are several other methods of refining gold, with aqua regia, with the vitriolic acid, with lead and other called cupellation, COPPELLING, or churning, with a composition of nitre, or sea-salt, green vitriol calcined, and brick-dust, called *comestione*, which the reader will find described under the articles ASSAYING, CEMENTATION, PARTING, REFINING, and TESTING.

GOLD, for the making of. See PHILOSOPHER'S STONE, and TRANSMUTATION.

GOLD beating, and GOLD beater's skin. See GOLD leaf. **GOLD, burnished,** is that which is polished with a steel instrument called a BURNISHER, if it be wrought gold; or gilding on metal; or with a wolf's tooth, if it be gilding in water. See GILDING.

GOLD chain. See CHAIN.

GOLD coin, or species of gold. See COIN and COINAGE.

Anderfon, in his History of Commerce, vol. 1. p. 174, dates the first coining of gold in England in the year 1344; for it appears by 15 Edw. III. cap. 36. that three different coins of gold were then ordered to be coined; viz. one of the value of six shillings, being the weight of two small florins of Florence; a second of half that

value and weight; and a third of a quarter of the first. The gold was 23 carats 31 grains fine, with half a grain of alloy. Three other gold coins were also coined in the same year; viz. one of 6s. 8d. value, called a gold noble; others half that value, called *maile* nobles; and a third a quarter of the first, called *farling*, or farthing noble. For an instrument invented by Mr. Boyle for detecting counterfeit gold coin, see *FLUENT LEAD-STONE*.

GOLD colour on glass and china. See GLASS, GILDING, and PORCELAIN.

GOLD-coloured glazing. See GLAZING.

GOLD-coloured metal is produced by melting zinc with copper. According to the purity of the zinc and copper, the proportion in which they are mixed, and the intimacy of their union, the compound metal proves more or less malleable, and approaches more or less to the colour of gold. Some direct the zinc to be taken only in a fifth or sixth part of the weight of the copper, and others in an equal weight or more. Dr. Lewis observes, from the result of many experiments, that both with the smallest and largest of these quantities of zinc, the metal proves more like gold than with the intermediate proportions.

The colour of these compounds is improved by a small mixture of some other metallic bodies. Cramer recommends the addition of a small quantity of pure tin to copper, melted with a fourth or fifth part of zinc, which forms a compound metal, that acquires, on being well cleaned, and laid in the air for some days, a superficial colour of fine gold. Goodrich says that iron has the best effect; with the proportions of ten parts of zinc, eight of copper, and one of iron-silica, he produced a metal of a fine smooth grain, compact, hard, and bright, and of a beautiful gold colour. By making the copper first into brass, and then melting it with a suitable quantity of zinc, a metal may be obtained of superior quality to that produced either by melting the copper and zinc, or by impregnating the copper with zinc, by cementation and fusion with alumina; which is a method sometimes practised. A very ingenious artist, says Dr. Lewis, who now prepares a gold-coloured metal in great perfection, has a fine kind of brass made on purpose for this use. The union of the copper and zinc in fusion, succeeds best and with least loss of the zinc, according to Dr. Lewis, by using a mixture of black flux and borax, or a composition of twelve parts of green glass powdered, six parts of potash, two of borax, and one of powdered charcoal; when this flux is fused in the crucible, the copper and zinc are dropped into it, and when they appear perfectly melted, they are to be well stirred together with an iron rod, and expeditiously poured out. The same flux will serve for melting several small quantities of the metal. Dr. Hooke gives the following receipt for making a gold-coloured metal: eight parts of distilled verdigris, i. e. of verdigris purified by solution in distilled vinegar and crystallization, and four parts of Alexandrian tincture, with two of nitre, and one of borax, are directed to be mixed with oil to the consistence of pap; then melted in a crucible, and poured into a flat mould first well warmed. A composition of this kind is called *AURUM FOLIUM*.

The following method is recommended by Homberg for giving a gold colour to copper, without the addition of zinc: making an amalgam of one part pure copper, and three parts quicksilver; see AMALGAMATION OF COPPER: boil this in river-water for two hours, then distil off the quicksilver in a retort, and cohobate it once; take out the copper and file it, and it will be found of a beautiful gold colour, more ductile than common copper, and extremely well fitted for watch-work, gilding, and the finer machines and utensils. The celebrated Mr. Pott affirms, that a gold-coloured metal may be made from a mixture of copper and tin, and directs it to be compounded in the following manner: take out half ounce of tin alloy, and four half ounces of copper; melt them well together in a close luted crucible, with a strong fire; or, take one half ounce of the pure tin cut in pieces, and sixteen half ounces of pure copper beaten into thin plates; lay the tin between the copper-plates, lute the crucible close, and melt with a strong fire. See *PRIME'S METAL*, and *TIN*, &c.

Silver is tarnished superficially, by certain vapours, as that of purified urine, to a colour like that of gold; that several artists have been used in France to prevent frauds of this kind with regard to wire and lace.

GOLD-coloured pigments. See PIGMENTS.

GOLD-coloured porcelain. See LACQUER.

GOLD, Crown. See STANDARD.

GOLD, Dutch. is a kind of leaf used in GILDING, &c. which is copper gilt, or brass beaten into leaves like the genuine GOLD leaf.

GOLD, farthing of. See FARTHING.

VOL. II. N° 135.

GOLD, East or West, is that procured by the fire of all its impurities, and all alloy. The Latins call it *aurum purum*, *aurum primum*, *aurum stratum*, *aurum citatum*. The moderns frequently call it *gold of twenty-four carats*; but, in reality, there is no such thing as gold in very pure; and there is always wanting at least a quarter of a carat. Gold of twenty-two carats has one part of silver, and another of copper; that of twenty-three carats has half a part, i. e. half a twenty-fourth of each. Bouteau maintains, that the electrum of the ancients was gold of nineteen carats; or four parts gold, and a fifth silver.

From an ordinance of king John of France, it appears that the gold then struck at Paris was of 19 carats 1.503 and yet it is added that it was the best and finest gold then known on earth. See STANDARD.

GOLD, fulminating, aurum fulminans. See AURUM and Chemical History of GOLD, above.

GOLD, leaf, or beaten GOLD, is gold beaten with a hammer into exceedingly thin leaves. It is altogether to consider the French to which a body of gold is thus reduced. In an experiment of Reaumur's, forty-two square inches and three tenths of gold leaf, weighed one grain 17.5 and Mr. Boyle found that fifty and seven tenths weighed but a grain. As a cubic inch of gold weighs 492.5 grains, the thickness of the gold leaf examined by the one was the 20735th, and of that by the other only the 24852nd part of an inch. See DUCTILITY OF GOLD.

This gold is beat on a smooth block of black marble, from two hundred to six hundred pounds in weight, and about nine inches square on the upper surface, fixed into the middle of a wooden frame, about two feet square, so as that the surface of the marble and frame form one even plane. Three of the sides are furnished with a high ledge, and the front, which is open, has a leather flap fastened to it, which the gold-beater uses as an apron, for preserving the fragments of gold that fall off. Three hammers are employed in this business, having two round and somewhat convex faces; the first, called the catch hammer, is about four inches in diameter, and weighs sixteen or sixteen pounds; the second, called the shoeing hammer, weighs about twelve pounds, and is about the same diameter; the third, called the gold hammer, or finishing hammer, weighs ten or eleven pounds, and is nearly of the same width. The French use four hammers, differing both in size and shape from those of our workmen.

The gold-beaters also use three kinds of animal membranes, some of which are laid between the leaves to prevent their uniting together, and others over them to defend them from injury by the action of the hammer. For the outside cover, they use common parchment made of sheep skin; for interlaying with the gold, fish, the smoothest and closest vellum made of calves skin; and afterwards, the much finer skins of ox-gut, stripped off from the large straight gut flat open, prepared on purpose for this use, and hence called *gold-beaters' skin*. The general process of their preparation, is said to consist in applying one upon another, by the smooth sides, in a moist state, to which they readily adhere and unite inseparably, stretching them on a frame, and carefully scraping off the fat and rough matter, so as to leave only the fine exterior membrane of the gut; beating them between double leaves of paper, to force out the remaining unctuality; moistening them once or twice with an infusion of warm spices, and finally drying and pressing them. It is said, that some calcined gypsum, or plaster of Paris, is rubbed with a bar's foot, both on the vellum and ox-gut skins, which fill up their pores, and prevent the gold from sticking. These skins, after seventy or eighty repetitions, become unfit for use; but their virtue may be restored by interlaying them with leaves of paper moistened with vinegar or white wine, beating them for a whole day, and afterwards rubbing them over with plaster of Paris; and even holes of them may be repaired by the dextrous application of fresh skins.

GOLD, the manner of preparing and beating. They first melt a quantity of the purest gold in a blacklead crucible, with some borax, in a wind furnace, and pour it into an iron ingot mould, six or eight inches long, and 3 or 4 of an inch wide, previously greased and heated; the bar of gold is made red-hot and forged on an anvil into a long plate, which is farther extended, by being passed repeatedly between polished steel rollers, till it becomes a ribbon, as thin as paper. This ribbon is divided by compasses, and cut with sheers into equal pieces, which are forged on an anvil till they are an inch square, and afterwards well scaled. Two ounces of gold, which is the quantity melted at a time, make a hundred and fifty of these squares, so that each of them weighs six grains and two fifths; and as 492.5 grains of gold make a cubic inch, the thickness of the square pieces is about the 760th part of an inch.

leaves. All these squares are interlaid with leaves of vellum, three or four inches square; one leaf being laid between every two of them, and about twenty more of the leaves are laid on the outside; over this is drawn a parchment case, open at both ends, and over this end, at, in a contrary direction, so that the vellum and gold leaves are kept tight and close. The whole is then beaten with the heaviest hammer, till the gold is stretched to the extent of the vellum; the piece, taken out of this case or mould, is cut in four with a steel knife; and the fit hundred pieces thus produced are interlaid, in the same manner, with pieces of the cut-out skins, five inches square. The beating is repeated with a lighter hammer, till the golden plates have acquired the extent of the skins, when they are divided into four, by a piece of cane cut to an edge. The whole number of leaves is then divided into four parts, which are interlaid, as before, and beaten separately, till they are stretched for the third time to the size of the skins. The French repeat the division and beating once more. After the last beating, the leaves are taken up by the end of a cane instrument, and being thrown flat on a leather cushion, are cut to a size, one by one, with a square frame of cane made of a proper shape, or with a frame of wood edged with cane. They are then fitted into books of twenty-five leaves each, the paper of which is well smoothed, and rubbed with red bole to prevent their sticking to it. The size of the French gold leaves is from some what less than three inches to 31 square; that of ours, from three inches to 31. The French prepare what they call green gold leaf, from a composition of one part of copper and two of silver, with eighty of gold; but Dr. Lewis observes that such an admixture gives no greenness to gold, and that this kind of leaf is made from the same fine gold, as the highest gold-coloured foil, the greenish hue being a superficial taint given to the gold in some part of the process; this leaf is chiefly used for the gilding of books. A kind of leaf, called *party gold*, is formed by laying a thick leaf of silver, and a thinner one of gold, flat on one another; they are then beated and pressed together, so as to unite and cohere; and being beaten into fine leaves, as in the foregoing process, the gold, though only in quantity a fourth of that of the silver, extends over it and every where covers it.

GOLD, million of, a phrase often used to signify a million of crowns.

GOLD MINER. See MONEY and COIN.

GOLD, Mosaic, is gold applied in pannels on a proper ground, disseminated into squares, lozenges, and other compartments; part of which is thinned to raise or heighten the relief. See MOSAIC.

GOLD PLATES for examining are generally made of doct gold, whose fineness is from 231 to 235 carats, and the finest gold is the best for this purpose, unless where some parts of the gold are left bare and unpolished, as in watch-cases, jewel-boxes, &c. for which purpose a mixture of alloy is necessary, and silver is preferred to copper, because the latter dissolves the plates to tarnish, and turn green. See ENAMELLING.

GOLD, potable, or auran potable. See AURUM POTABLE, and the Chemical history of GOLD.

GOLD POWDER, for the purposes of GILDING, may be made by grinding gold leaf with honey; see Shell-GOLD: by distilling to dryness a solution of gold in aqua regia; by evaporating the mercury from an amalgam of gold, taking care well to stir the mass near the end of the process; or by precipitating gold from its solution in aqua regia by applying it to a solution of common green vitriol in water, or some copper, &c. See Chemical history of GOLD.

GOLD precipitate with tin, called also, from its supposed discoverer, *cola casti*, is prepared with great care both in dissolving the tin, and diluting the solution. For this purpose, a mixture of two parts of aquafortis, and one of spirit of salt, is supposed to be the best menstruum for the tin. Into this mixture some fine black tin, granulated, is to be let fall, grain by grain, waiting till one grain is dissolved before another is dropped in, that the dissolution may go on slowly, without any heat or discharge of fumes. The gold is dissolved in common aqua regia; and a few drops of this solution being mixed with some ounces of pure water, as many drops of the solution of tin are added. If the mixture changes immediately to a clear bright purplish red colour, the due degree of dilution has been determined; if the colour appears dull, a greater quantity of water must be added for the rest of the solution. After the mixture has deposited its red matter, and become clear, a little more of the tin solution is to be dropped in, for dissolving and precipitating any gold that may still remain in it; the liquor being then poured off, the precipitate is washed and

dried. Lewis's Com. Phil. Techn. p. 176. See RUBY GLASS.

For other methods of precipitating gold, see Chemical history of GOLD.

GOLD, pure. See QUEEN'S GOLD.

GOLD, pure, is that used by the gilders and illuminers, and with which gold letters are written. It is made by grinding gold leaves, or gold beater's fragments, with a little honey, and afterwards separating the honey from the powdered gold by means of water. When the honey is washed away, the gold may be put on paper, or kept in shells; whence its name. When it is also, it is diluted with gum-water, or lops-luds. The German *guten-powder*, prepared from the Dutch gold leaf in the same manner, is generally used, and when it is well scoured with varnish, answers the end in *japan's* GILDING, as well as the genuine.

GOLD-FINE for varnished GILDING is prepared of one pound and a half of tobacco-pipe clay, half an ounce of red chalk, a quarter of an ounce of black lead, forty drops of sweet oil, and three drams of pure tallow; grind the clay, chalk, and black-lead, separately, very fine in water; then mix them together, add the oil and tallow and grind the mixture to a due consistence.

GOLD-FINE of japaners may be made by pulverizing gum animi and asphaltum, of each one ounce; red-lead, six drams of oil, and union, of each one ounce and a half, mixing them with a pound of linseed oil, and boiling them, observing to stir them till the whole be incorporated, and appears, on growing cold, of the consistence of tar; strain the mixture through a flannel, and keep it, stopped up in a bottle, for use. When it is used, it must be ground with as much vermilion, as will give it an opake body, and diluted with oil of turpentine, so that it may be worked freely with the pencil. A simple preparation consists of one pound of linseed oil, and four ounces of gum animi; powder the gum, and mix it gradually with the boiling oil; let it continue to boil, till it becomes of the consistence of tar; strain it through a coarse cloth, keep and use it as the other.

GOLD-FINISH, or as some chuse to express it, *finer-finish*, the art of making vessels, medals and ornaments in gold or silver. The goldsmith's work is either performed in the mould, or beat out with the hammer or other engine. All works that have raised figures are cast in moulds, and afterwards polished and finished; plates or dishes of silver or gold are beat out from thin flat plates, and tankards and other vessels of that kind are formed of plates folded together, and their mouldings are beat, not cast. The business of the goldsmith formerly required much more labour than it does at present, for they were obliged to hammer the metal from the ingots to the thickness they wanted; but there are now invented flattening-mills, which reduce metal to the thickness that is required, at a very small expence. The goldsmith is to make his own quality, and for that reason ought to be a good designer, and have a taste in sculpture; he also ought to know enough of metallurgy to be able to alloy mixed metals, and to mix the alloy.

The goldsmith in London employs several hands under him, for the various articles of his trade. In this great city there are always hands that excel in every particular branch of the trade, and there is commonly employment enough for every one in his particular branch. The jeweller, the jewel-box and toy-maker, the fillet-turner, the gilder, the burnisher, the chaser, the reiner, and the gold-beater, are all employed by and under the goldsmith.

GOLD-SMITH, Company of, in London. See COMPANY.

GOLD thread, or spun gold, is a flattened gilt wire, wrapped or laid over a thread of yellow silk, by twisting it with a wheel and iron bobbin. By means of a curious but complex machinery, a number of threads is thus twisted at once by the turning of one wheel. The principal art consists in so regulating the motion, that the several circumsolutions of the flatted wire on each thread may just touch one another, and form, as it were, one continued covering. At Milan, it is said, they make a sort of flatted wire, gilt only on one side, which is wound upon the thread, so that only the gilt side appears. There is also a gilt copper wire, made in the same manner as the gilt silver, chiefly at Nuremberg; and the confederate of France requires it to be spun on flaxen or hempen thread. The Chinese, instead of flatted gilt wire, use slips of gilt paper, which they interweave in their stuffs and twill upon silk threads.

GOLD, tin of, is a kind of money of account, used by the Dutch, and in some other countries, containing a hundred thousand florins.

A hundred pounds of, or in, gold, is found to weigh two pounds ten ounces: the sum in silver weighs twenty-

fix pounds four ounces. Twenty-two pence, in copper farthings and halfpence, weigh one pound avoirdupois. A tun of gold, at 4 $\frac{1}{2}$ the ounce, amounts to 50000*l*. A tun of silver, at 5*l* 2*s* the ounce, to 5000*l*. A pound sterling of gold, to 40*l*. An ounce is worth 4*l*. The penny-weight 4*s*. One grain 2*d*. A pound of sterling silver amounts to 3*l* 2*s*. An ounce is worth 5*s* 2*d*. The penny-weight 3*d*, and something more; one grain a halfpenny. A pound of silver avoirdupois comes to 3*l* 5*s* 3*d* halfpenny.

GOLD, virgin, is pure gold, just as it is taken out of the mines, before it has undergone any action or preparation of fire; whence the Greeks call it *argyros*.

Such is the *aurum purum*, or gold-dust, and that got by lution in the lavaderos in Chili: it is added, that there are masses or lumps of pure gold found in the mines, particularly those of Hungary. Accordingly, in the emperor's collection, are still preserved several plates of gold said to have been thus found.

Virgin gold is sometimes very pale, and is so soft that it may be moulded into any figure with the hand; it even takes an impression from a seal, like the softest wax. To harden it, as also to heighten its colour, they mix emery with it.

GOLD, white. See PLATINA.

GOLD wire is cylindrical ingot of silver, above an inch thick, two feet in length, and weighing about twenty pounds, superficially gilt, or covered with gold, at the fire, and afterwards drawn successively through a great number of little round holes of a wire-drawing iron, each less than the other, till it be sometimes no bigger than a hair of the head. There is very little wire made entirely of gold, and this chiefly for one particular purpose, that of filigree work.

It is amazing to what degree of fineness the gold is here drawn; and yet it still keeps firm together, and never shows the least signs of the silver underneath it. The reader may see a computation hereof, as also a more particular account of the manner of proceeding, under the article DUCTILITY of gold.

GOLD wire flatted, is the former wire flatted between two rollers of polished steel, to fit it to be spun in silk, or to be used flat as it is, without spinning, in certain stuffs, laces, embroideries, &c.

Manner of forming GOLD wire and GOLD thread, both round and flat. The first object, which is of the utmost consequence, is the choice of the purest gold; for on this chiefly depends the beauty and durability of the colour of the laces, brocades, and other commodities prepared from it. To a difference in this respect, the boasted superiority of the French laces to the generality of those made in England, till of late, has been wholly owing. With regard to the silver that forms the body of the wire, it is said that there is an advantage in its being silvered. The French silver for gilding it said to be alloyed with five or six penny-weight, and ours with twelve penny weight of copper, in the pound troy. The gold is employed in thick leaves, which are applied all over the silver rod, and pushed down smooth with a steel brush. Several of these leaves are laid over one another, as the gilding is required to be more or less thick. The smallest proportion allowed by act of parliament, is 100 grains of gold to a pound, or 5760 grains of silver. The largest proportion for the best double gilt wire was formerly 120 grains to a pound; but the proportion of gold has been of late increased. The first part of the drawing process, as well as the preparation and gilding of the silver rod, is performed by the refiner, who uses plates of hardened steel, with a piece of tough iron welded on the back to prevent the steel from breaking. The holes in these plates are conical, being larger in the back part than in the steel, that the rod may not be scratched against the outer edge, and that they may contain beeswax, which makes the rod pass more freely, and preserves the gold from being rubbed off. One end of the rod, made smaller than the rest, is pushed through a hole that will admit it, when the plate has been properly secured, and laid hold of by strong pincers, called clamps, adapted to the purpose; to these pincers which are so contrived, that the force, which pulls them horizontally, serves at the same time to press them together, a rope is fastened by one end, and the other end goes round a capstan with cross bars, which requires the strength of several men to turn it. The rod, thus drawn through, is well nealed; it is then passed through the next hole; and the nealing and drawing are repeated, till, being reduced to about the size of a large quill, it is delivered in coils to the wire-drawers. The remainder of the process requires plates of a different quality, which are brought from Lyons in France, and are formed of a metallic mass, whose prevailing ingredient is iron: the holes are drilled in them here. These plates are of two

sorts; some of considerable thickness, for the wire in its larger state, and others about half as thick, for the finer wire. In the use of these plates, furnished with a variety of holes, the dexterity of the workman principally consists in adapting the hole to the wire: for this purpose he uses a brass plate, called a *size*, on which is measured, by means of notches like steps at one end, the increase which a certain length of wire should gain in passing through a fresh hole; and if the wire is found to stretch too much in two times, the hole is widened or contracted. Slits of different widths, in thick polished iron rings, serve also as gauges for measuring the degree of fineness of the wire.

The wire-drawer's process begins with nealing the large wire received from the refiner, which he does, by placing it, coiled up, on some lighted charcoal, in a cylindrical cavity, called the pit, under a chimney, and throwing more burning charcoal over it. When it is cooled by being quenched in water, one end is pushed through the first hole in the thick plate, and fastened to an upright wooden cylinder five or eight inches in diameter, in the top of which are two flanges, and through these is passed the long arm of a handle, by which the cylinder is turned on its axis by several men. By this process, called *drawling*, the wire is frequently nealed and quenched, after passing through every hole, or every other hole, till it is brought to about the size of the small end of a tobacco-pipe; and then cut into portions for the fine wire-drawers. In this last part of the wire-drawing process, nealing is not necessary; but the wire is waxed at every hole. The contrivance for drawing the wire through the plate in this case, when less force is needed, is a kind of wooden wheel placed horizontally, leaving in its upper surface small holes at different distances from the axis, into one or other of which, according to the force required, is inserted the end of an upright handle, whose upper end is received in a hole made in a cross bar above. From this wire it wound off upon a smaller cylinder, called a *rochet*, placed on the spindle of a spinning-wheel; and this cylinder being placed behind the plate, the wire is again drawn through upon the first; and being brought to the proper fineness, it is nealed for the flattening mill. In this nealing, the wire is wound on a large hollow copper bobbin, set upright, including small coal, and encompassed with lighted charcoal or small coal, communicating a gradual heat. The wire, in this state, must be watched and removed from the heat, when it appears of the proper colour. The next operation is that of the flattening-mill, which consists of two perfectly round and exquisitely polished rollers, formed internally of iron, and welded over with a plate of refined steel: these rollers are placed with their axis parallel, and their circumferences nearly in contact; they are both turned with one handle: the lowermost is about ten inches in diameter, the upper little more than two, and their width or thickness is about an inch and a quarter. These rolls are sometimes replenished with putty, prepared by calcining a mixture of lead and tin. The wire, unwinding from a bobbin, and passing between the leaves of a book gently pressed, and through a narrow slit in an upright piece of wood, called a *kech*, is directed by a small conical hole in a piece of iron, called a *guide*, to any particular part of the width of the rollers, some of the best of which are capable of receiving, by this contrivance, forty threads. When the wire is flatted between the rollers, it is wound again on a bobbin, which is turned by a wheel, fixed on the axis of one of the rolls, and so proportioned, that the motion of the bobbin just keeps pace with that of the rolls. See on the subject of the preceding articles, Dict. of Chemistry, Eng. ed. 1777, and particularly Dr. Lewis's Philosophical Commerce of Arts pages.

GOLD, in Medicine and Chemistry. The Chemists make several preparations of gold for medicinal uses; as salts, mercuries, and tinctures of gold; but it is a point not yet well agreed on, whether gold has any real property whereby it may be of use in medicine.

Some mechanical physicians have had a notion, that if the particles of gold could be rendered fine enough, so as to circulate with the blood, that it would prove more effectual in the cure of diseases than mercury. But this is a mere hypothesis. The *aurum fulminans* has been used, and other preparations of gold are to be met with in authors; but they seem to meet with little credit among modern practitioners.

GOLD, in Heraldry, is one of the METALS, more usually called by the French game, OR.

GOLD-FINCH, in Ornithology, is the *FRINGILLA carduelis* of Linnaeus. This bird is peculiarly beautiful in its colour, the elegance of its form, and the music of its notes. The bill is white, tipped with black, the huf being surrounded with a ring of rich scarlet feathers; a black line

from the corner of the mouth to the eyes; the cheeks are white; the top of the head is black; the hind part of the head is white; the back, rump, and breast, are of a fine pale tawny brown; the belly is white; the covert feathers of the wings, in the male, are black; in the female, brown; the quill-feathers black, marked in their middle with a beautiful yellow, the tips white; the tail black, but most of the feathers are marked near their ends with a white spot; the legs are white. The black and yellow in the wings of the female are less brilliant than those of the male. The young bird, before it moults, is grey on the head, and called by the bird catchers a *grey-pate*. There is another variety of *gold-finch*, which is *lesser*, and called a *chorevich*, from the manner in which it concludes its jerk: it is distinguished from the common sort by a white streak, or by two, and sometimes three white spots under the throat. The *gold-finch* is very docile, and its note is very sweet. In winter these birds feed on seeds, particularly those of the thistle. They are fond of orchards, and often build in an apple or pear-tree; their nest is elegantly formed of fine roots, liver-worts, &c. on the outside, and within lined with wool and hair. The *gold-finch* lays five white eggs, marked with deep purple spots on the upper end. Some have supposed this bird to be the *amantia* of the ancients, but Pennant appropriates that appellation to the *LINNET*. *Brit. Zool.* vol. i. p. 332, &c.

GOLD FISH, in Ichthyology, is the *CYPRINUS auratus* of LINNÆUS. The form of this fish resembles the carp; its nostrils are tubular; the tail is naturally bifid, but in many is trifid, and in some quadrifid; the anal fins are placed opposite to each other like the ventral fins, which disposition constitutes the most distinguishing character of this species: the colours are various; some are marked with a fine blue, with brown, with bright silver; but the general predominant colour is gold of a surprising splendour. They were first introduced into England about the year 1691, but not generally known before 1728. In China, the most beautiful kinds are taken in a small lake in the province of Cho-Kyang, and are said to grow to the size of our largest herring; with an eye they have been known to arrive at the length of eight inches. Pennant.

GOLD FISH is also a name by which some authors have called the *SAPIO* of STAZI, from the yellow colouring it frequently has on the covering of the gills.

GOLD OF POMEY, *myrica*, in Botany, a genus of the *tribe myricaceae* *platanifolia* class. Its characters are these: the empanment of the flower is composed of four oblong coloured leaves; the flower hath four rosette-like obtuse petals placed in form of a cross; it hath six stamina the length of the petals, four of which are a little longer than the other; in the centre is situated an oval germen, which afterward becomes a turbinated, heart-shaped, little pod, having two valves, with the rigid style in the top, inclosing roundish seeds. Miller enumerates five species, and LINNÆUS eight.

This plant is possessed of the same virtues with the *RAFFINIA*, but is not recommended for any particular purpose. Its oil, however, obtained from it by expression, is excellent for rendering the skin soft and smooth.

GOLDEN, something that has a relation to gold, or contains of gold, is valuable like gold, or the like.

GOLDEN BULL, *Bulla aurea*. See BULL.

GOLDEN BULL was a figure of a bull, which the Israelites cast in that metal, and set up in the wilderness to worship, during Moses' absence in the mount, and which that legislator, at his return, burnt, ground to powder, and mixed with the water the people were to drink of, as related Exod. xxxii.

The commentators have been greatly divided on this article: the pulverizing of gold, and rendering it potable, is an operation in chemistry of the last difficulty; and it is hard to conceive how it should be done at that time, before chemistry was ever heard of, and in a wilderness too! many, therefore, suppose it done by a miracle; and the rest, who allow of nothing supernatural in it, advance nothing but conjectures as to the manner of the process.

Moses could not have done it by simple calcination, nor amalgamation, nor antimony, nor calcination; nor is there one of those operations that quadrates with the text.

M. Stahl has endeavoured to remove this difficulty. The method Moses made use of, in making his *aureum potable*, according to this author, was the same with that which now obtains; only, instead of *urine*, he made use of the Egyptian natron, which is common enough throughout the East.

GOLDEN RAIN, a name by which some call the *RAMUNCULUS*, or *crucifera*.

GOLDEN RY, in Ornithology. See DUCK.

GOLDEN RY, a species of RY. See CHRYSORHIN.

GOLDEN RY, in the *Ancient Mythology*, was the son of Boreas of the tem, upon which Phrynia and Hella are supposed to have swam over the sea to Colchis; and which, being sacrificed to Jupiter, was hung upon a tree in the grove of Mars, guarded by two brazen-headed bulls, and a monstrous dragon that never slept; but at last taken and carried off by Jason and the ARGONAUTS. Many authors have endeavoured to show, that this fable is an allegorical representation of some real history, particularly of the philosophers flood.

Order of the GOLDEN FLECE is a military order, instituted by Philip the Good, duke of Burgundy, in 1430.

It took its denomination from the representation of the golden fleece, borne by the knights on their collars, which consisted of flims and fleeces. The king of Spain is now grand-master of the order, in quality of duke of Burgundy: the number of knights is fixed in thirty-one.

It is usually said to have been instituted on occasion of an immense profit which that prince made by wool; though others will have a chemical mystery couched under it, as under that famous one of the ancients, which the adepts contend to be no other than the secret of the elixir, written on the fleece of a sheep.

GOLDEN FLOWER GENTLE, a name sometimes given to several species of the *AMARANTH*.

GOLDEN HIND, in Ornithology, a water-fowl, otherwise called *anas arctica*. See DUCK.

GOLDEN HANG-WORT, in Botany. See HAWKWEED.

GOLDEN HANG-WORT. See ADIANTUM ACUTUM.

GOLDEN HANG-WORT. See HAWKWEED.

GOLDEN NUMBER, in Chronology. See CYCLE of the moon and NUMBERS.

GOLDEN PREBENDARY of Hereford. See PREBENDARY.

GOLDEN RAY, or *SARACENI WOOD-WORT*, *virga aurea*, or *fulgens*, in Botany, a genus of the *hypericaceae* *polyphaga* *hypericifolia* class. Its characters are these: it has a compound flower, made up of hermaphrodite stamens and female half flowers, included in one long imbricated empanment; the hermaphrodite flowers, which compose the disk, are funnel-shaped, cut into five parts at the brim; they have five very short hair-like stamina, terminated by cylindrical funnels, and a crowned germen, supporting a slender style as long as the stigma, crowned by a blind open stigma; the germen afterward turns to a single seed, crowned with hairy down; the female half flowers are tongue-shaped, included in three parts; these have a crowned germen with a slender style, crowned by two revolving stigmas, and are succeeded by a single seed, like the hermaphrodite flowers. Miller enumerates thirty-three species, and LINNÆUS fourteen.

We have several very beautiful species of this plant cultivated in our gardens, where they are very great and lasting ornaments, beginning to flower in May, and one kind or other of them continuing to flower till October. They are all easily propagated by parting their roots in spring, before they begin to shoot; they will grow in any soil or situation, but they succeed best in a light fresh earth and an open exposure, and should be planted in the middle of large flower-beds: they are perennial plants, dying down to the ground as soon as they have ripened their seeds, but rising again the following spring; their seeds sown will very freely grow, and often produce varieties in the flower. Miller.

The species of *golden ray*, called the *virga aurea angustifolia minus serrata*, or narrow-leaved *golden ray* less sawed, with linear spear-shaped leaves almost entire, and flowers in clusters sitting close at the wings of the stalk, grows wild in woods and heaths, and flowers in August. The flowers and leaves of this species are recommended as corroborants and aperients, in urinary obstructions, nephritic calcs, ulcerations of the bladder, catarrhes, and insipient dropsies. It communicates its virtues to water and spirit. The extracts are the best preparations. Lewis.

GOLDEN RAY. See BOREA.

GOLDEN RULE, in Arithmetic, a rule or praxis of great use and extent in the art of numbers, whereby we find a fourth proportional to three quantities given. The *Golden Rule* is also called the *Rule of Three* and *Rule of Proportion*. See its nature and use under the article *RULE of Three*.

GOLDEN SAMPHIRE is a species of the *genus* or *class* *ELÆAGNACEAE*, with narrow leafy leaves ending in three points. It grows naturally on the sea-coasts in many parts of England, and is sometimes sold in the London market for the true SAMPHIRE, though entirely destitute of its warm aromatic taste.

GOLDEN SAXIFRAGE. See GILL-SAXIFRAGE.

GOLDEN STALK, order of the. See STALK.

GOLDEN SALT, of antimony. See ANTIMONY.

GOLDEN THISTLE, in Botany. See GOLDEN THISTLE.

GOLDSINNY, in *Ichthyology*, a fish discovered on the coast of Cornwall, in the whole form of the body, fins, teeth, and fins, resembling the *WRAHSE*, which is said never to exceed a palm in length; near the tail is a remarkable black spot; the first rays of the dorsal fin are tinged with black. Pennant.

GOLDYLOCKS, *Goldestockia*, in *Botany*, a genus of the *polyanthus polyanthus* class. Its characters are these: the flower is composed of many hermaphrodite stamens, contained in an imbricated envelope, which are tubular and funnel-shaped, cut into five parts at the brim, and have five short slender filaments; they have an oblong germ, which becomes a single, oblong, compressed seed, crowned with hairy down. Miller reckons five species, and Linnaeus nine.

GOLYLOCKS is also a name sometimes given to the *GNA-PHALUM*.

GOLF, or *GOLF*, the name of a diversion or exercise, much used in Scotland, and played upon the laws or links, as they are there called.

It consists in driving a ball with clubs, between two goals or holes, half a mile or a mile asunder. He who can do this with the fewest strokes of his club is the conqueror.

GOLPS, in *Heraldry*, are roundels or tinctures, of a purple colour.

GOLTBURGENSES *terra*, in the *Historia Medica*, a whitish earth, used in the towns of Germany and Italy as an alstringent, a cordial, and a sudorific, but little known among the English physicians. It is dug in many parts of Germany, as Goldberg and Sanger, and Lignitz in Silesia; but particularly at this time in the neighbourhood of Haffes, in the bishopric of Liege, in the circle of Westphalia. It is taken up there in considerable quantities, and usually is tested with the impression of an eagle, and with its old name *Goldeberg's terra* under it. It was imagined to contain some particles of silver, and thence to derive some of its virtues: on this account Montanus called it *argentum lineae*, but experience shews that it doth not contain a particle of that metal. It is a dense compact earth of a dull greyish white, soft and friable, and adheres firmly to the tongue, and makes no effervescence with acids.

GOMARA, or *GOMARI*, in *Natural History*, a name given by some of the old authors to *talca*; some have also called it *gumara*: this last seems only a corruption of the word *gummaris*, and that of *gummaris* or *gummaris*, a name this stone was often called by among the Greek writers of the middle ages. Some have also called the felenites by this name, and it seems to have originally belonged to that fossil; but both being foliaceous fossils, both were often confounded together.

GOMATUS, in *Ichthyology*, a name used by many for the *GURNARD*, more frequently called by authors *paralichthys*.

GOMER, or *OMER*, an Hebrew measure. See *CONVUL*.

GOMPHOSIS, in *Anatomy*, a kind of articulation of the bones, wherein one is chafed, or fitted immovably into another, after the manner of a peg or nail.

The word is *gompheus*, formed of *gomphe*, *clavis*, a nail or peg.

The teeth are set in the jaws by *gomphosis*. See *TEETH* and *MAXILLA*.

GOMPHEA, in *Botany*, *glaberrima*, a genus of the *pentandria digyna* class. Its characters are these: the flower hath a large coloured envelope, which is permanent; the petal is erect, and cut into five parts at the brim, which spread open; and it hath five stamens, scarcely discernible, situated in the brim of the nectarium; in the centre is situated an oval pointed germ, which becomes one large roundish seed, inclosed in a thin crusty capsule with one cell. There are seven species, natives of the East and West Indies. See *AMARAN-THOIDEA*.

GOMUTIRA *stiptica*, in *Natural History*, the name given by the Indians to a kind of fossil, found in great plenty on the mount Vindy in the East Indies, in places, as they observe, where the cows frequently urinate. It is a bituminous substance, and after calcination the residuum is given in cases of internal ulcers and in gonorrhoea. The Indians suppose it is formed by the drying up of the cow's urine.

GONAGRA, in *Anatomy*, the gout in the knee. See *GOUT*.

The word is composed of *goni*, *hues*, and *agra*, *captura*, *trahens*.

GONAMBUCH, in *Ornithology*, a name by which may be called the *gambuli*, or *humming-bird*, the smallest of all birds.

GONANDINA, the name of a Brazilian tree, remarkable for its great height.

GONARCHA, a term in the ancient dialling. Mr. Perault, in his notes on Vitruvius, lib. ix. cap. 9. takes Vol. II. N° 156.

the *gonarchia* to have been a dial drawn on divers surfaces or planes; some of which being horizontal, others vertical, others oblique, &c. formed divers angles.

Whence the appellation, from *goni*, *hues*, or *gonia*, *angle*.

GONDOLA, a little flat boat, very long and narrow, chiefly used at Venice to row on the canal.

The word is Italian, *gondola*. Du-Cange derives it from the vulgar Greek *gonola*, a boat, or *gonola*. Lancelotti derives it from *gonia*, a term in Athenian for a sort of raft.

The middle fixed *gonolas* are upwards of thirty feet long, and foot broad: they always terminate at each end in a very sharp point, which is called perpendicularly to the tail length of a man.

The admiral of the Venetian gonoliers, in passing along their narrow canal, is very remarkable: there are usually two to each *gonola*, and they row by pulling before them. The first-man sits on the left side of the *gonola*; the hind-man is placed on the stern, that he may see the head over the back covering of the *gonola*, and steer his ear, which is very long, on the right side of the *gonola*.

GONDOLA is also the name of a pillage-boat of six or eight oars, used in other parts of the coast of Italy.

GONDOLA *belli*, in *Natural History*, a name given by authors to a peculiar kind of *corallus* *glabra*, supposed, in some degree, to represent the shape of a Venetian boat. It is of the genus of the *butidum*, and there are seven species of it.

GONFALON, or *GONFARON*, a kind of round tent, borne as a canopy, at the head of the processions of the principal churches at Rome, in case of rain; its verge of banner serving for a shelter, where there is not a great deal of attendance.

GONGOLARA, in *Botany*, a name by which Imperatus has called a very beautiful sea plant, known among botanical writers by the name of *gongolara*, or *ERICA* *maritima*, the sea heath.

GONGRINA, a word used by many authors to express a round and hard tubercle in the trunk of a tree. It is also used in medicine to express any round and hard tumour of the neck parts, but principally a bronchocoele.

GONGRUS, in *Ichthyology*, a name given by Alian, Applan, and some other of the Greek writers, to the *CONGRUS* or *SAURUS*.

GONIOMETRICAL *lines*, derived from *goni*, *angle*, and *metron*, *measure*, in *Geometry*, lines used for measuring or determining the quantity of angles. Such are lines, tangents, secants, versed lines, &c.

We have a paper by Mr. Jones, in the Philosophical Transactions, containing a commodious disposition of equations for exhibiting the relations of *goniometrical* lines, from whence a multitude of curious theorems may be derived. See Phil. Trans. N° 483. sect. 20.

GONION, in *Ichthyology*, a name given by the French to the common *STURGEON*.

GONIOSIS, a term used by Archigenes to express a peculiar sort of pulse, which seems to strike, not with the whole circle of the artery, but with an angle of it; or when the elevated artery is not felt like the curve of a circle, but like the vertex of a triangle. The cause of this is an imbecility in the motion of the blood, which renders it incapable of elevating the whole artery.

GONORYNCHUS, in *Ichthyology*, a species of cyprinus with eight rays in the anal fin, a cylindrical body, and bifid tail. It is found at the Cape of Good Hope.

GONORRHEA, *gonorrhoea*, in *Medicine*, an involuntary flux or dripping of seed, or other humour, by the penis, without erection or titillation.

The word is formed of the Greek *goni*, *genitura*, *sem*; and *rho*, *flux*, *efflux*.

The *gonorrhoea* is of two kinds; the one simple or benign, the other violent or venereal.

GONORRHOEA, *simplex*, that without virus or malignity, takes its rise from violent exercises and straining; the immoderate use of hot foods and spirituous liquors, cold, violent or frequent purging, excessive coition, &c. It is cured by indulging, overindulging foods, broths, &c.

This species is again divided into two: the one *vera*, the *gonorrhoea vera*, wherein the humour discharged is real seed; the other *spuria*, the *gonorrhoea spuria*, wherein the dripping humour is not seed, but a whitish and mild matter from the glands about the *PRESTATA* and *URETHRA*.

This latter kind bears some resemblance to the floor albos or whites in women, and frequently remains a long time without much diminution of the patient's strength. Some call it a *interitall gonorrhoea*. Its seat is in the glands of the prostate and urethra, which are either too much relaxed, or ulcerated. See *GLEET*.

GONORRHOEA, *venerea*, *gonorrhoea venerea*, arises from some impure commerce, and is the first stage of the

venereal disease, being what we popularly call a CLAP. The parts here primarily affected, are the prostate in men, and lacunae in women, which, being ulcerated by some contagious matter received in coition, occasion an itching, with a small degree of pain in the genitals, and then come, first, a whitish watery liquor that stains the linen with spots, whose edges are of a darker colour than the centre, accompanied with a small degree of titillation, particularly at the time of making water, and, by degrees, with greater heat and more acute pain, perceived chiefly at the extremity of the urinary passage, where a slight degree of redness and inflammation likewise begins to appear: this liquor afterwards grows yellowish, then flatter, and at length greenish or bluish, sometimes of a bloody colour, and frequently fetid.

It is attended with a tension and inflammation of the yard, and an ardor urinae, or sharpness of urine, which gives a painful sensation in the emission, and is discharged sparingly and with difficulty; the urinary passage being torn and excoriated by the acrimony of the humour.

Hence arise tumors of the prepuce and glands, with oedema on the scrotum, and sometimes in the urethra.

The cause of the venereal gonorrhoea, according to M. Laitre, is some sharp or acid humour, heated, rectified, and exhaled at the time of coition, from the internal parts of the pudendum of a woman infected, and lodged in the urethra of the man. It has different seats in the body; sometimes it only sits on Cowper's mucous glands, sometimes on the prostate, and sometimes on the vesiculae seminales; sometimes it possesses two, and sometimes all three of those places at once.

From this diversity of seats of the gonorrhoea virulenta, M. Laitre makes two sorts; simple, which only affects one of the three parts; compound or complicated, where several are affected.

That seated in the mucous glands, he observes, may remain simple through the whole course of the disease, because the mouths of those glands open into the urethra on each and half on this side the prostate, and also look down towards the glands, so that their liquor is easily discharged. The other two sorts mutually produce each other, because the ducts of the vesiculae seminales terminate in the urethra in the middle of those of the prostate, so that there is an easy communication between them.

That seated in the mucous glands is much the rarest case, and is the easiest cured. The cure is effected by emollient cataplasms and fomentations upon the part, and a half-bath. *Mem. de l'Acad. ann. 1711.*

For the other species more powerful means are to be used. The principal remedies are mercurial purges, an emulsion of green hemp-seed, cuttle-fish-bone, turpentine, fresh sassafras, &c. We have likewise great commendations of green precipitate of mercury and mercurial dulcis. Half terebinthine balsam, prepared with a gentle fire, of fresh balsam and oil of turpentine, is much applauded, where the heat is great about the rim and genitals; it is also camphor. An infusion of cinchona in wine is the nostrum of a noted Dutch physician. Resin of the wood guscum is also recommended; and balsam of Copiba is held a sort of specific: to which must be added antimonium diaphoreticum, berosodium minerals, water wherein mercury has been boiled, infusions of lime-water, mercurius dulcis, saccharum lactum, &c.

Fistula's method of curing the gonorrhoea virulenta, is as follows: in the beginning of the disease he purges with a laxative pilula of fecula, salt of tartar, and milliniflowers; and gives the patient where for his drink. After three or four days spent in this purging, if the scalding of the urine and the flux be abated, and the colour and consistence of the matter improved, he administers boluses of turpentine and chaponicum for six or seven days; and if they keep the body loose, so much the better. By all means, abstinence is to be avoided, the gonorrhoea being scarce ever known to degenerate into a pox, unless too hastily stopped.

Dr Eberly directs the cure of the gonorrhoea to begin with a gentle cathartic of callos, fens, crystal mineral, tamarinds, aithers, and rhubarb, administered every other day; then diarrhetics, particularly those of turpentine; and lastly, gentle astringents, as mineral waters, crocus maris astringens, tincture of roses, tincture of coral in cochineal, &c.

A light injection may sometimes be carried off in a few days by bathing the parts with warm milk and water, and injecting frequently up the urethra a little sweet oil or infused tea, warmed to the degree of new milk. Astringent injections should be very cautiously used, and only in a slight and recent stage of the disorder; an injection of this kind may be prepared by dissolving half a dram of the sugar of lead in six or seven ounces of rose-water;

and a small syringe full of it, a little warm, may be injected up the urethra five or six times a day, and continued till the running stops. Gentle cooling purges are always proper in the gonorrhoea: for this purpose, the patient may take six drams, or an ounce of salts, and half an ounce of manna, dissolved in a pint of boiling water, whey, or water-gruel, early in the morning; or, two drams of lens and an ounce of tamarinds may be infused all night in a pint of boiling water, and half an ounce of Glauber's salts dissolved in the strained infusion; and a tea-spoon of this may be taken every half hour till it operates. Or, the patient may take two or three tea-spoonfuls of the following electary at night, and the same quantity in the morning: take of the lenitive electary four ounces, cream of tartar two ounces, powdered jalap two drams, rhubarb one dram, and as much of the syrup of roses as will serve to make the whole into a soft electary.

When the symptoms of inflammation are high, bleeding is always necessary at the beginning. Diarrhetics are also proper in this stage of the disorder: an ounce of ulter, and two ounces of gum Arabic, pounded together, and divided into twenty-four doses, one of which may be taken frequently, will answer this purpose; or, equal parts of gum Arabic and cream of tartar, powdered together, and taken four or five times a day, in the quantity of a tea-spoonful, will serve both as a diuretic and laxative.

Emollient clysters are very useful, when the pain and inflammation are seated high towards the neck of the bladder, and soft poultices, made of the flower of linseed, or of wheat bread and milk, softened with fresh butter, or sweet oil, or cloths wrung out of warm water, or bladders filled with warm milk and water, may be applied with great benefit. If this treatment fails to effect a cure, the patient must have recourse to the use of mercury: two at night and one in the morning of the common mercurial pills will be a sufficient dose at first, which may be diminished or increased according to its effect; or, two or three grains of calomel may be formed into a bolus with the conserve of hips, and taken at bedtime, and the dose gradually increased to eight or ten grains; or, again, corrosive sublimate may be taken in the manner prescribed under *VENEREAL DISEASES*. These mercurial medicines should never be taken in such quantities as to raise a salivation, unless in a very slight degree: for preventing which, they may be combined with purgatives; and the griping or purging of the mercury may be prevented by taking with the above pills or bolus half a dram or two scruples of MARSHMALLOW, or of the Japone confection. See *COUGHS* *Japone*. Mercury may be taken in a liquid form, by rubbing a dram of it with two drams of gum Arabic reduced to a mucilage in a marble mortar, till the mucilage disappears, and adding gradually during the restitution, half an ounce of balsamic syrup, and eight ounces of simple cinnamon water: two table-spoonfuls of this solution may be taken night and morning. Mercury may also be administered by means of friction: a dram of mercurial ointment, prepared by rubbing together equal quantities of hog's lard and quicksilver, may be used in a line.

The best time for rubbing it on the body is at night, and the most proper place is the inner side of the thighs. In whatever way mercury is administered, its use must be persisted in as long as any venosity is observed to remain. When, by the preceding treatment, the pain and heat are abated, and the quantity of the discharged matter is lessened, and it becomes whitish, thick, and void of all smell, which symptoms constitute the third or last stage of the gonorrhoea, stringent or agglutinating medicines may be cautiously used: but it is dangerous to stop the running till the contagion is removed, because, in this case, swelled testicles, a sore throat, buboes, or some other symptoms of the pox, will ensue; and when this happens, the discharge must be again promoted by purges, and more mercury must be used. At first, therefore, it may be proper to mix gentle astringents with purgative medicines; thus, to two ounces of the lenitive electary add cream of tartar and powdered rhubarb, of each half an ounce, and balsam of Capivi an ounce and a half; take of these, made into an electary with the syrup of pale roses, about the quantity of a large nutmeg, evening and morning: the patient may then proceed to the use of Venice turpentine, the Persian balsam, balsam of Gilead, &c. or, instead of these, he may take fifteen or twenty drops of the acid elixir of vitriol in a glass of red wine, or a cup of the infusion of the bark, twice or thrice a day. If the running still continues, without any signs of virulence, injections may be used; for this purpose gum Arabic may be dissolved in three or four ounces of rose water, and ten or twelve grains of sugar of lead may be added to the solution: two or three drams of

this, made a little warm, and adapted in strength to the nature of the case, may be daily injected up the urethra with a small syringe. If all these means should fail to stop the discharge, though the virulence is entirely removed, the disorder is denominated a GLEET.

regard must be paid to the regimen in the several stages of the *gonorrhoea*. In the first stage, the person, who suspects that he has been infected, should observe a cooling regimen, and avoid every thing of a heating nature, as wines, spirituous liquors, rich sauces, spiced, salted, high-seasoned, and smoke-dried provisions, and also all aromatic and stimulating vegetables, as onions, mustard, cinnamon, ginger, &c. His food should consist chiefly of mild vegetables, milk, broths, puddings, gruels, &c. his drink may be barley-water, milk and water, decoctions of marsh-mallows and liquorice, linseed tea, or clear whey, which he should use freely. He should avoid violent exercise and cold. When the inflammation has subsided, or in the second stage of the disorder, all intemperance should be avoided: the food should be light, plain, and of easy digestion; and a little wine, diluted with much water, may be allowed, but spirituous liquors are dangerous. In the last stage, the patient should use moderate exercise in the open air; his diet should be rice, millet, jellies, and other things of a strengthening nature; his drink may be distilled water, claret or port with the addition of water. Beckon's *Domestic Med.* p. 534, &c. See *VENEREAL DISEASES*.

GYNALGIA, of *γυνή*, *hine*, and *αλγία*, *gala*, a term used by some authors to express a violent pain in the knee.

GOOD, or *Goodness*, denotes whatever tends or conduces to preserve or improve human nature or society, in opposition to *evil*, which tends to destroy, injure, or impair the same.

Hence *good* is divided by the philosophers into, 1. *Beneficent*, *private good*, which is that whereby a thing tends to preserve, &c. itself; under which comes that popular division of *good* of body, mind, and fortune.

2. *Beneficent*, *common*, whatever promotes the interest and welfare of society; as all the civil offices, &c.

Good, in *Metaphysics*, or *metaphysical good*, called also *absolute* or *real good*, and *good for it*, is the essential perfection or integrity of a thing, whereby it has every thing that belongs to its nature.

In this sense, all things that are, are *good*, inasmuch as they have the perfections naturally belonging to things of their kind. Thus, a thinking substance is *good*, or perfect, as it has all the essential attributes of thought; so an extended substance is *good*, as it possesses all the parts necessary to constitute it such.

In effect, as it is absurd to imagine a being without its essence, so is it to imagine a being without the requisites of its essence; so that it appears an error in some philosophers, who divide things into good or perfect, and evil or imperfect. See *ESSENCE*.

Others define metaphysical, or transcendental *goodness*, by congruency with the divine will, which, they say, constitutes the measure of all real *goodness*.

Good, *physical* or *natural*, is that whereby a thing possesses all things necessary to its *bona esse*, i. e. its well-being, or second perfection, and to the performance of its functions and uses.

In this sense, physical *goodness* coincides with physical perfection.

To this are required the several powers and faculties, in their proper degree; a due situation, figure, and proportion of parts, &c.

Note, beside absolute physical *goodness*, there may be a relative one; as in foods, which to one are salutary, to another poison, &c. To this head also belong the things *good pro tempore*, or according to circumstances; as the amputation of a mortified limb, &c.

Natural *good* may be otherwise defined to be that which makes or denominates a being happy, or prepares him for happiness; or, at least, prevents or removes his misery; accordingly, *good* is either objective or formal; objective *good* is that which makes us happy; formal *good*, or the pleasure resulting from the application of the faculty to the object, is that which denominates us happy.

Good, *moral* or *ethical*, is the agreement of a thinking, reasonable being, and of the habit, acts, and inclinations thereof with the dictates of right reason, and the will of the Creator, as discovered by natural light. See *VIRTUE*.

In order to this, it is not enough that a thing done, said, thought, desired, be just and *good*; but it must be done, thought, &c. well, i. e. from *good* principles, and to good ends.

Others define moral *good* more largely. *Moral*, which they also call *relative good*, according to them, is something that is good to another, or that tends some

way to the perfection thereof. In this sense they divide it into three kinds, *longitum*, *paritum*, and *vile*.

The first, *bonum longitum*, is what agrees with right reason, and is desirable for itself; as all things virtuous; e. g. to love God, respect our parents, &c. It is considered without any regard to pleasure; not that there is no pleasure annexed to it. *Zeno* and the Stoics allow of no other *good*; those of the body, &c. they call *communia*, *inconveniens*, not *good*.

Bonum paritum is that which is *good*, as it tends to give us pleasure, and is desired on that account; but without any repugnance to virtue or right reason; as music to the ears, painting to the eyes, &c.

Bonum vile, or *communia*, is that which is *good* on account of something else for which it is desired; as money, riches, &c.

Good, *chief*, *prevalent*, or *fortior*, *fortius bonum*, is that, the enjoyment of which renders men truly and completely happy. The school philosophers call this *chief good* man into that which is simple and adequately fit, and beyond which there can be no other; and an inferior, subordinate kind, which is, in some measure, attainable in this imperfect state. The last they call *subalternum*, and the former *supremum bonum*. The chief or *fortior bonum*, according to the idea, exhibited of it from the original, natural, and universal perceptions of all mankind, is something agreeable to our nature, subsistent to well-being, inaccessible to all pains and miseries, durable, self-sufficient, and indestructible; and this consists, say Mr. Harris, in rectitude of conduct, or in living perpetually according to the law of nature, which is congruous to nature, and rejecting what is contrary, making our end that selecting and rejecting only. Three Treatises, &c. 1765, p. 121, &c. 205, &c.

Philosophers are divided as to what the *chief good* of man consists in; whether in the good of fortune, of body, or of mind. Some hold riches and honours the latter *good*; others, as Aristotle, and the Epicurean school, bodily pleasures; and others, as *Zeno*, and the Stoics, virtue, or living according to nature. The Peripatetics agreed with the Stoics in maintaining that virtue is the *summum bonum*; but the Stoics asserted further, that virtue was the *only good*; whilst the Peripatetics denied, with reason, that virtue was self-sufficient, and therefore required several other things as auxiliaries, such as health, prosperity, friends, &c. which are to the virtuous man in the nature of instruments or ornaments to his felicity. An excellent writer lays down the following criteria or characteristics of the *summum bonum*, or *chief good*, which reason can demonstrate to be actually desired for man: it is something which all men, if not wanting to themselves, may be possessed of; it is one and the same to all mankind; and while in itself fixed to make the possessor happy, is not prevented in its operation by some other thing which keeps him from relishing it; and as to the highest *good* which it is possible for man to enjoy, it must be referred to no other, but all others must be embraced for the sake of this; and it must be sufficient to furnish a happiness adequate to the capacities of human nature, and of equal duration; i. e. it must be not only perfect whilst it lasts, but everlasting. According to these characters we may infer, that neither the *good* of fortune, nor those of the body, nor even virtue itself, constitute the *chief good*. Virtue rightly understood is the perfection of human nature; it is the instrument of obtaining happiness; but this alone will not make a man happy; it is further necessary that he be perfect as to his, or happy in the circumstances of his being; and, therefore, natural reason demonstrates, that the favour of God, secured by virtue, is properly man's *supremum good*. Grove's System of Moral Philosophy, vol. 1. part I. passim. See *EPICUREANS*, *PERIPATETICS*, and *STOICS*.

Good-will. See *BENEVOLENCE*.

Good-worship. See *MORAL* and *SUPEREROGATION*.

Good, *showing*, *bona fides*, in *Latin* style, is particularly used for an exact carriage or behaviour of a subject towards the king and his high people; to which sense men, upon their misbehaviour, are bound.

The justices are empowered by 24 Edw. III. cap. 1. to bind in this manner all them that be not of good fame; under which general expression, it is holden that a man may be bound to his *good behaviour* for causes of scandal, *contra bene mori*, as well as *contra bonum* i. e. for haughty bawdy-wooies; for keeping bad women in his own house; or for words tending to scandalize the government, or in abuse of the officers of justice, especially in the execution of their office; a justice may also bind over all night-walkers, exors-droppers, such as keep suspicious company, or are reported to be pilferers and robbers, common drunkards, whore-masters, the putative fathers of bastards, cheats, idle vagabonds, and any other persons,

persons, whose misbehaviour may reasonably bring their within the general words of the statute. Persons of this description may be bound, with one or more forsores, in a RECOGNIZANCE or obligation to the king, entered on record, and taken in some court, or by some judicial officer, whereby the parties acknowledge themselves to be indebted to the crown in the sum required. *s. gr. 1001.* with condition to be void and of none effect, provided that they behave themselves well, either generally or specially, for the time therein limited, as for one or more years, or for life. This recognizance, if taken by a justice of the peace, must be certified to the next sessions, by 3 Hen. VII. cap. 1, and if the condition of it be broken, the recognizance becomes forfeited or absolute; and being extracted or extracted, *s. c.* taken out from among the other records, and sent up to the exchequer, the party and his forsores are become the king's debtors, and are sued for the several sums in which they are bound. All persons under the king's protection may obtain such security, upon due cause shown; and the justice may be compelled to grant it by a mandamus writ, called *supplicavit*; but this writ is seldom used, for, when application is made to the superior courts, they usually take the recognizances there, under the direction of the justice at the bar. *1. cap. 8.* A recognizance may be discharged, either by the demise of the king, or by the death of the principal party bound thereby, or by order of the court to which it is certified by the justice. He that is bound to show himself, is more strictly bound than to the peace; because, whereas the peace is not broken without an affray, battery, or such like, this duty of *showing* may be forfeited by the number of a man's company, or by his or their weapons or arms, by speaking words tending to sedition, or by committing any of those acts of misbehaviour which the recognizance was intended to prevent.

GOODS. See **ALLIES.**

GOODS. See **GOODS** and **PEACE.**

GOODS. See **TAXES.**

GOODS. *See, in Law,* and particularly the *Crail Laws*, include all kinds of effects, riches, lands, possessions, &c. There are two kinds of *goods*; *moveable*, *res movables* or *mobilia*; and *immovable*, called *res immovables* or *immobilia*.

It is a maxim in the civil jurisprudence, that he who confiscates the body, confiscates the *goods*; meaning, that all the effects of a person condemned to a capital punishment, or perpetual banishment, are forfeited to the king.

A man is said to bind himself body and *goods*, meaning, that besides his *body*, he obliges his person, and submits to remain in prison, provided he do not execute his promise.

Goods, again, are divided into, 1. *proper*, *paternal*, *fraternal*, *testamentary*; 2. *acquired* or *acquisita*, *alia quam hereditas* *res acquisita*; and, 3. *recepta*, *res et accipiuntur* *fructus* *fructus acquisita*.

Goods, again, are divided into *real* and *personal*. See **CHATELLE** and **ESTATE**. And, lastly, into *solid* or *free*, and *fructus* or *base*.

Goods belonging to the domain of the crown, *ad ipsum ipsellum*, cannot be alienated for ever, unless it be done by way of exchange; they may be sold under the faculty of perpetual redemption.

Goods, acquisition, adventitia, are those which arise otherwise than by succession from father or mother, or from direct ancestor to descendant. See **ADVENTITIOUS**.

Goods, alien, detrahe, those accruing from a dowry, and which the husband is not allowed to alienate. See **DOWRY**.

Goods, fugitive. See **FUGITIVE**.

Goods, personal. See **PARAPHRENALIA**.

Goods, prohibited. See **PROHIBITED**.

Goods, professional, professional, are those arising by direct succession.

Goods, recipient, were those which the wife might reserve the full property of to herself, and enjoy them independently of her husband; so called, in distinction from *solid* and *paraphernalia*.

Goods, vacant, vacuata, are those abandoned, or left at large, either because the heir renounces them, or that the defunct has no heir.

Goods, alienating. See **ALLOTING**.

Goods, assignment of. See **CONSIGNMENT**.

Goods, running of. See **RUNNING**.

GOODINGS, in *Sea-language*, are clamps of iron bolted on the stern-post of a ship, wherewith to hang the rudder and keep it steady; for which purpose there is a hole in each of them, to receive a correspondent spindle bolted on the back of the rudder, which turns thereby as upon hinges.

GOOLE, a breach in a sea-bank or wall; or a passage

worn by the flux and reflux of the sea. Vide 16 and 17 Car. II. cap. 11.

The word comes from the French *goulet*, the gullet or neck.

GOOSANDER, in *Ornithology*, the English name for the male *MERGAMER*; the female of that species having been universally esteemed a different bird, and called the *DUMMEL*, and *mergas certain longirostris*.

GOOSE, *anser*, forms an order of birds in the Linnæan system. See **ANSER**. The several species of *goose* belong to the genus of *ANAS* or *duck*, under this order. The common or domestic *goose* is a variety of the *anser ferus*, or wild *goose*; and derived from the *grey leg*, or *ten-pence* of latter, which is the only species that the Britons could take young and domesticate. The length of the *grey leg* is two feet nine inches, and the extent five feet: the bill is large and elevated, of a flesh-colour, edged with yellow; the nail white; the head and neck cinereous, mixed with yellow; the hind part of the neck very pale, and at the base a yellowish brown; the breast and belly are whitish, clouded with grey; the back grey; the lesser coverts of the wings almost white; the middle row deep cinereous, slightly edged with white; the primaries grey, tipped with black, and edged with white; the secondaries entirely black, and grey at their base; the quills of a deep ash colour, edged with white; the coverts of the tail and the wing-feathers of a pure white; the middle feathers of the tail dusky, tipped with white; the exterior feathers almost wholly white; the legs are of a flesh colour. This species remains in the fens during the whole year; breeds there, and hatches about eight or nine young, which are easily tamed, and their meat is much superior to that of the domestic *goose*. The common *goose* retains the whiteness of the coverts of the tail and wing-feathers of its wild state; but the variety of colours in the tame sort is less than in the other. *Some geese* are of vast longevity. Mr. Willoughby mentions an instance of one that attained eighty years. Multitudes of tame *geese* are kept in the fens of Lincolnshire; a single person will keep a thousand old *geese*, each of which will rear seven, so that towards the end of the season he will become master of eight thousand.

The *geese* are plucked five times in the year: the first plucking, in pursuance of this barbarous practice, is at Lady-day, for *feathering* and *quills*; and the fane is renewed, for feathers only, four times more between that and Michaelmas. See **FOWLS**.

There is another variety of the wild *goose*, called, from the shape of the nail of its bill resembling a horse-bean, the *bean goose*, which is somewhat smaller than the *grey leg*, and distinguished from it by a smaller bill, much compressed near the end, whitish, and sometimes pale red in the middle, and black at the base and nail. This species, which lights on corn-fields, and feeds much on the green wheat, comes to the fens in Lincolnshire in summer, never breeds there, but disappears in May. They fly very high, and make a cackling noise in their flight; they preserve a great regularity in their motions, sometimes forming a train line, and at other times assuming the shape of a wedge, for their more easy progress through the air.

There is also another species of wild *goose* known in this country, called the *lagher*, or *whitethroated goose*, being the female *anser erythrogastrus* of Linnæus, which is smaller than the former, and visits the fens and other parts of England during the winter, in small flocks; they keep always in marshy places, and never frequent the corn-fields: these are never seen after the middle of March. Mr. Pennant observes, that the *goose* was one of the forbidden foods of the Britons in the time of Cæsar. *Brit. Zool.* vol. II. p. 370. No.

Besides these, there are other kinds of *geese*, which Linnæus enumerates as species of the *ANAS*: such are, 1. The *ferus*, or *BARBACE*, being the male *anser erythrogastrus* of Linnæus. This is also in some places called *CRAB*. These birds appear in vast flocks during the winter, on the north-west coasts of this kingdom; they are very shy and wild, but, on being taken, grow as familiar as our tame *goose* in a few days: in February they quit our shores, and retire as far as Lapland, Greenland, and even Spitzbergen, to breed. They were formerly called *iron-geese*, from a mistaken notion that they were generated out of wood, or rather out of a species of shell, called the *spina anserina*, that is often found sticking to the bottoms of ships. Pennant.

2. The *hem-goose*, or *QUARTER*. This is the *anser boschalis* of Linnæus. These birds frequent our coasts in the winter, and are called in Ireland *henalis*, appearing in great numbers in August, and leaving it in March. They feed on the root of a long grass that grows in the water; are caught in nets placed across the rivers near Londonderry, Belfast, and Wexford, and much esteemed for

for their delicacy. Mr. Willoughby, Mr. Ray, and M. Drillon, describe the *hennet* and *breast* as different species; but Linnaeus makes them synonymous. Pennant.

3. The *asif* *Hispionet*, or *swan-geese*, being the *anas* *eximius* of Linnaeus, which always moves in a stately manner, and with its head erect like a swan. Its back is of a brownish grey, its belly white, and its breast a little tinged with a reddish brown; and it has a line of blackish brown running straight down the middle of the neck to the back.

4. The *asif* *Gambensis*, or *Gamba-geese*, which in figure and size resembles the *Majesty* duck, but has very long red legs, and a fine shining purple back; its belly is white, its back red, and its head has a red caruncle; but its most observable character is, that it has a strong spur standing out from the first joint of the wings, as some of the Brazilian birds described by Marguave have.

5. The *asif* *Canadensis*, *Canada-geese*, or *anas* *Canadensis* of Linnaeus: this is of the shape of the common *geese*, but a little longer in the body; its back is of a brownish grey, its rump black, its neck black at the bottom and white in every other part, its belly white, and its tail and wings black.

6. The *cat-geese*, or *read-geese*, which is about half the size of the common *geese*, and of a bluish grey on the back, and white at the belly. This is wild in the northern countries of England. Mr. Pennant supposes that this is the same with the *breast-geese*.

7. The *asif* *laurensis*, or *anas* *laurensis* of Linnaeus. See *Gulliver's* Duck. Linnaeus, Ray, and Pennant.

GOOSE, *anser*. See *EMER*.

GOOSE, *felat* or *felan*, sometimes called GANNET, the English name of a large water-fowl, called by authors *anser* *Bassanus*, and by Linnaeus *pelicanus* *Bassanus*. This bird is remarkable for the quickness of its flight; and, according to Martin, is derived from an Irish word expressive of its quality. See *Fab. II. Birds*, pp. 11. It is of the size of the common *geese*, and its wings are very long and capable of extending to a very remarkable breadth; its back is long and straight, and of a dusky grey, and a little hooked at the end; it has also near the hooked part two small appendages like teeth: it is naked behind the eyes; its mouth opens to a great width, and it seems to have no nostrils; but, in the place of them, has a long narrow running nearly the whole length of the bill; it has also a row of serratures or indentings all along, provided by nature for its holding fish more firmly: its feet are black, and all the four toes are connected by the same membrane: it is all over of a clear white when full grown, except that the larger wing-feathers have some blackness, and the head with age is apt to become yellow: its skin adheres but loosely to its flesh, and the young are mottled with grey and brown: from the corner of the mouth is a narrow slip of black bare skin, that extends to the hind part of the head; beneath the chin is another, which, like the pouch of the pelican, is dilatate, and of size sufficient to contain five or six whole herrings, which, in the breeding season, it carries at once to its mate or young: it flies well, but if it fall on the ground does not easily raise itself. They are birds of passage, and build in the island of the Bais in Scotland, and the rocks of St. Kilda, in vast numbers. Their first appearance is in March, and their continuance there till August or September; but, in general, the time of their breeding and of their departure seems to coincide with the arrival of the herring, and the migration of that fish, which is their principal food, out of these seas. It is probable that these birds attend the herrings and pilchards during their whole circuit round the British Islands. They are known to migrate as far south as the mouth of the Tagus, being frequently seen off Lisbon, during the month of December, pluming for spring, a kind of fish resembling, if not the same with our pilchards. Each female, if undisturbed, lays only one egg; but if that be taken away, it will lay another; and if that also is taken, a third; but never more than a season. The young *geese* are esteemed a great delicacy, and sell at a great price. Ray and Pennant.

GOOSE, *Magellanic*, *anser* *Magellanicus*, in Ornithology, the name given, though improperly, by Clusius, to a bird of the diver kind. It is a sea bird, and is usually very fat; it is of the size of the largest *geese*, and is black on the back and white on the belly; the neck is short and thick, and has a ring or circle of white feathers round it: its skin is thick and tough like that of a hog, and it has only two coriaceous or leather-like fans in the place of wings, hanging from its side like two arms, covered with a few feathers which are short and partly black, partly white, and by no means of any use to fly with, but very serviceable to the creature in swimming. It lives continually in the water, except at its breeding time; the tail is very short, and the beak as large as a

raven's, but not protruding on the top, but flat.

GOOSE-DUNG, in Agriculture and Medicine. See DUNG and CHENOCOPRUS.

GOOSE-FEET, or WILD ORACH, or Good Henry, *chamaedion*, in Botany, a genus of the *pentandria* *alignia* class. Its characters are these: the flower has no petals, but in the centre hath five stamina placed opposite to the leaves of the empanement; it hath a round germin, which afterward becomes a five-cornered fruit inclosed in the empanement, containing not roundish dejected seed.

There are many species of this genus, some of which grow naturally on daublands and the sides of ditches in moist parts of England, where they often become very troublesome weeds.

The first species, called also English mercury, all-good, or good Henry, is found growing naturally in shady lanes, but it is doubtful whether the seeds have not been call out of gardens originally, because this plant was formerly cultivated in kitchen-gardens; and in some of the northern countries the people still prefer it in gardens as an esculent herb, which in the spring they boil as a substitute for spinach; but as the latter is a much better herb, it has justly obtained the preference.

GOOSE-GRASS. See CLEAVES.

GOOSE-NECK, or *Sea-lugwag*, is a sort of iron hook fitted on the inner end of a boom, and introduced into a clamp of iron or eye-bolt, which encircles the mast, or is fixed to some other place in the ship, so that it may be unhooked at pleasure.

GOOSE-WINGS of a sail denote the clues or lower corners of a ship's main-fall or fore-dail, when the middle part is full of or tied up to the yard.

GOOSE-WING, at Sea, a sailing manner of fitting a sail, which is thus performed: when a ship sails before a wind, or with a quarter-wind, and in a fresh gale, the seamen sometimes, to make the more hale, unlash the mizen yard, and then they launch out both dail and yard over the quarter on the lee-bow, lashing gages at the further end, to keep the yard steady with the boom, and this boom out the mizen-chest. This they do to give the ship the more way, which otherwise, with these winds, the mizen sail could not do; and this sail so fitted, is called a *goose-wing*, and sometimes a *sliding-sail*.

GOOSEBERRY-BUSH, *argentea*, in Botany. Its characters are these: the flower has a permanent empanement, cut into five parts at the top, which is concave and coloured; it has five small, obtuse, erect petals, which rise from the border of the empanement; and five awl-shaped stamina, which are inserted into the empanement; the germin is situated below the flower, and afterward becomes a globular berry, having a navel, with one cell, which is filled with roundish compressed seeds inclosed in a pulp. There are five species, including several varieties, bearing the names of the persons who raised them. This is a species of the *rupestris* in the Linnaean system. See CURRENT-ORP.

The *gooseberry-bush* is propagated either by suckers or cuttings, but the latter way is preferable, as the roots are less subject to shoot out suckers afterwards.

The best season for planting the cuttings is in autumn, just before the leaves begin to fall; observing always to take the handsomest shoots, and to pick them from such branches as produce the greatest quantity of fruit. The cuttings should be about six or eight inches long, and should be planted in a bed of light earth exposed to the morning sun; they must be planted about three inches deep, and watered to help their taking root. The shoots should be rubbed off from these plants as they put out, except those at the top, that there may be a regular stem. In the October following, they should be removed to a bed of fine light earth, and planted in rows at three feet distance, and one foot asunder in the rows. They should remain here one year, and the crooked branches at times be cut off, as also the lower ones, so as to keep a clean stem about a foot above the ground. They will be then fit to plant out where they are to stand, which should be in a light sandy loam. They should be kept from the shade of other trees; and to have the fruit in its utmost perfection, should be set in an exposed place in rows of eight feet asunder, and each of the shrubs six feet from the others in the rows. The best time for transplanting them is in October, when the leaves begin to decay. Miller.

GOOSEBERRY of Barbados. See *Melon* THISTLE.

GOOSEBERRY-TREE, *American*, *maliflora*, in Botany, a genus of the *diandria* *monogamia* class. Its characters are these: the flower has five roundish petals, which are inserted into the border of a permanent empanement; and ten stamens, terminated by long recurved filaments under the flower is situated a roundish germin, which

turus to a berry with five cells, covered by the empalement which crowns it, and contains many small seeds. There are sixteen species, natives of the warm parts of America. Miller.

GOOSEBERRY-gall, in *Natural History*, the name given by authors to a species of protuberances of the gall kind, found very frequently on the oak. They are of a roundish figure, and sometimes adhere to the tree by a short pedicle, but more frequently by a part of their spheric surface. They are usually found on the under side of the leaves of the oak, but sometimes on the young shoots, and sometimes on the pedicles of the leaves.

They are most frequent in spring, but they are found at all times when the leaves are upon the trees. These galls are greenish at first, and afterwards become yellowish, and finally red, in which last state they very much resemble the small red gooseberry. They are very soft to the touch, and when opened are found to contain a juicy substance, with a cavity in the middle, in which there is lodged a single insect. This, according to the time in which the gall is opened, is found in the form of a white worm, or else of a white chrysalis, or finally of a small short-bodied four-winged fly of a black colour; for the creature does not leave the gall to go through any of its changes, but passes all its state in it. The gall, in all these cases, is found whole and unharmed; but if one is opened in which there is a hole pierced, this is sure to be found empty, that being the passage by which the fly has made its way out. Resum. Hist. Inf. vol. vi. p. 214.

GOOSEBERRY-worm, in *Natural History*, the name of an insect, found very frequently on the gooseberry-bushes, and usually supposed to be a caterpillar, but differing essentially from that genus of animals, and being one of those which the French call *gossier-chenilles*. It has a round head, and has twenty-two legs, and finally becomes not a butterfly, but a common four-winged fly. This worm is at first of a greenish colour, with some yellow variegations, and several black tubercles; but on the last change of its skin it becomes whitish or cream-coloured, and loses its tubercles. Resum. Hist. Inf. vol. ix. p. 18.

GOR, a name given by some writers to a very lofty tree, which bears a fruit like the chestnut; it grows principally on the banks of the river Niger, and that not near the sea, but far up the country.

GOOSE-neck, in *Ornithology*, the name of a bird of the gallinaceous kind, called by authors the *lagopus alpestris*, and by many the moor-cock, or coal game; it is of the shape of the partridge, but is half as large again. Its beak is black and stout, and it is very remarkable for the bare space over its eyes, which is very broad and of a fine bright red, and in the cock is surrounded by a prominence of the same bright colour, bare of feathers, and furnished like a cock's comb. The male is also distinguished from the female, by having a black plume at the base of the bill interspersed with frequent white spots, and some large white spots near the origin of the under chap: the male is also richer than the female in all parts, and on his throat and breast is of a fair red, without the mixture of any other colour. The head, neck, back, and wings are all variegated with red and black; the breast and belly are of the same colours with the back, but on the breast there are some variegations of white. The legs and feet are covered with a very long and thick plumage to the very ends of the toes; the wings are brownish, with some reddish variegations; and the tail is almost wholly black. It is seldom found but on the tops of very high hills, and is very common in Derbyshire, Yorkshire, and Wales, where it feeds on mountain berries and the tops of heath. It lays seven or eight eggs, which are of a mixed red and black colour, and are all over covered with small spots, except for one or two spaces, which are clear near the small end. The young brood follow the hen during the whole summer: in the winter they join in flocks of forty or fifty, and are remarkably shy and wild. This is a very well-tailed bird. The Italians call this, as well as the *lagopus*, by the common name of *franziska*, and Mr. Ray imagines that the *lagopus* of Pliney and this are indeed the same species of bird, though different in colour; but Mr. Pennant observes that the account left us by Pliney seems too brief and uncertain to determine, at this time, what species he intended; and that the *franziska* is not the same with our grouse is evident from the figure exhibited of it by Mr. Edwards. Ray and Pennant.

GORAIS, in *Ichthyology*, a name used by some authors for the more common species of the *CAVARIUS*; the third species, as it is called by Gessner, &c.

GORCEE, or **GOUR**, denotes a wear. By Stat. 25 Edw. III. cap. 4. it is ordained, that all *gorces*, mills, weirs, &c. levied or set up, whereby the king's ships and boats

are disturbed, and cannot pass in any river, shall be utterly pulled down, without being renewed. Sir Edward Coke derives this word from *gorge*, a deep pit of water, and calls it a *gor*, or *gall*; but this seems to be a mistake, for in Doomsday it is called *gort* and *gorf*, the old French word for a wear.

GORDIAN, a term in *History*. **GORDIAN knot** was a knot made in the leathers or harness of the christ of Gordius, king of Phrygia, and father of Midas: it was very intricate, that there was no finding where it began or ended.

The inhabitants had a tradition, that the oracle had declared, that he should be master of Asia who could untie this knot. Alexander having undertaken it, and fearing that, if he should not be able to effect it, it would be deemed an ill augury, and prove a check in the way of his conquest, cut it asunder with his sword: and thus, says Quintus Curtius, either accomplished the oracle, or eluded it. But Aristotle gives a different account of this matter. See *Arian*, lib. iii. cap. 20. and *Plut.* in *Vit. Alex.*

Some will have the phrase derived from Gordius, who tied the fatal knot; others from Gordium, a city in Phrygia, where the knot was made.

GORDONIA, libly born in *Botany*, a genus of the *monadelphia polyandria* class. Mr. Miller has erroneously classed this elegant American evergreen-tree under the genus of *laurus*, and Linnæus under that of *apocynum*; but Mr. Ellis has made it a distinct genus, under the name of *Gordonia*, in compliment to Mr. James Gordon, some time a distinguished personage and resident in the neighbourhood of London. Its characters are these: the perianthium consists of five concave, roundish, downy leaves, hairy on their edges; the flower is composed of five large, fleshy, concave, inverted-oval petals, united at the base, which includes a funnel-shaped fleshy substance, like a nectarium, surrounding the germens; the filaments of the stamens are numerous and linear, inserted in the top of the funnel-shaped tube, but equally distinct from each other; the anthers are of an oval form and erect, having a cell on each side full of farina of a globular shape; the germens are oval and acuminate towards the top, where the style begins: the style is short, and formed with five small ridges on the sides, which terminate in five acute filaments, disposed horizontally in a radiated form; on the upper part of each of these is a longitudinal cavity, covered with down: the capsule, which is egg-shaped and acuminate at the top, is of a woody confidence, and opens, when ripe, into five valves with five cells; each of which contains two seeds that are kidney-shaped, and winged obliquely on one side. *Phil. Trans.* vol. ix. N^o 44. p. 578, 579.

GORE, in *Heraldry, denotes one of the regular ARRANGEMENTS, used, according to Goulton, to denote a sword. It consists of two arches or curve lines, drawn, one from the sinister chief, the other from the sinister base, and meeting in an acute angle in the middle of the feet-point, as represented in *Tab. II. Heraldry*, fig. 65.*

GOREING, or **GORING**, is said of a sail when set slanting, so that it is broader at the clew than at the mast, as all top-sails and top-gallant-sails are.

GOREL, a name or title given to the prince of Georgia. The *gori* is always a Mahometan. The lord of Persia obliges him to observe the religion of the Alcoran, in order to preserve the dignity of *gori* in his family.

GORGES, in *Falconry*, is the uppermost bag or stomach of a hawk or falcon, being that which receives the food the first.

The *gorge*, *ingloris*, is the same, in birds of prey, with what we call the *crop* or *esop*. When the bird is fed, he is said to be *gorged*.

GORGES, in *Architecture*, denotes a sort of concave moulding, wider but not so deep as a *scotia*; used chiefly in frames, chambrases, &c. See *Tab. Archit.* fig. 6 and 8.

GORGE of a chimney is that part between the chambrasse and the crowning of the mantle. Of this there are divers forms; straight, perpendicular, in form of a bell, &c. **GORGE** is sometimes also used for a moulding that is concave in the upper part, and convex at bottom; more properly called *GOLA* and *EXCAVATUS*.

GORGES is also used for the neck of a column; more properly called *colure* and *anacolure*.

GORGES, in *Fortification*, the entrance of a *BAVION*, or of a *SAVILLON* or other out-work.

The **GORGES** of a *balloon* is what remains of the sides of the polygon of a place, after terminating the curtains; in which case it makes an angle in the centre of the bastion. Such is *AHD*, *Tab. Fortif.* fig. 1. In the bastions, the *gor* is a right line on the curtain, reaching between the two bastions.

GORGE of a half-moon or ravine, is the space between the two ends of their faces next the place.

Gorge of the other out-works is the interval betwixt their sides next the ditch.

All the gorges are to be made destitute of parapets; otherwise the besiegers, having taken possession of a work, might make use thereof to defend themselves from the foot of the place: so that they are only fortified with palisades, to prevent a surprise.

GORGE, *Half the GORGE*, **DEMI GORGE**, that part of the polygon between the flank and the centre of the bastion; as A H.

GORGED, in *Heraldry*, is when a crown, coronet, or the like thing, is borne about the neck of a lion, a swan, &c. In that case they say, the lion or cygnus is *gorged* with a ducal coronet, &c.

GORGON is also used when the gorge or neck of a peacock, swan, or the like bird, is of a different colour or metal from the rest.

GORGON, among *Farmers*, &c. signifies as much as swelled. In which sense they say, the legs of a horse are *gorged* the palfrey-joint is *gorged*; you must walk him out, to *disgorge* his shoulder.

GORGERIN, a part of the ancient armour, being that which covered the throat or neck of a person armed at all points.

GORGERIN, or **GORGE**, in *Architecture*, the little *frons*, in the Doric capital, between the astragal, at the top of the shaft of the column, and the anulets. See *Tab. Archit. fig. 25. N° 18*.

Some call it *calcarium*. Vitruvius gives it the name *hypotrachelium*.

GORGET, in *Military affairs*, a piece of brass or silver, worn by the officers of foot upon their breasts when on duty. The *gorget* hangs round the neck by a ribband; they are sometimes gilded, and have commonly some device engraven on them; as the sovereign's, or even the colonel's coat of arms, crest or cypher.

GORGET, or **GORGETT**, in *Surgery*, is the name which the French give to the concave or annulated *conductor*, used in *LITHOTOMY*. See *Tab. III. Surgery, fig. 30*. In *fig. 31*, there is exhibited the *gorget*, as it has been improved by Mr. Le Cat, and which he calls *gorget creux et blanc*. A is a ring for passing the middle finger of a right hand, which *grippe* the handle G. B is another ring, which is slid by the fore-finger towards *d*, to push the blade *a* out of the groove F F. The figure expresses the instrument in the state in which it is at the very instant when the incision is made into the neck of the bladder. The same fore-finger draws the piece B back towards A, when the operator intends to make the blades return into the groove F F, where they lie hid, while he introduces the instrument from *d* to *e*, in order to secure the pieces *a*, *b*, *c*, *d*, *e*, *f*, in their proper situation. The pins which bind the hinges *a*, *b*, *c*, must not be in the centre of the pieces, but as they are expressed in the figure: where *a* is pretty near the outer edge, and the other two, *b*, *c*, on the opposite side; so that, when the ring B is thrust forward, the hinge *b* may bend and slide out of the groove F, by making the angle *a b c*. Phil. Trans. vol. xlv. p. 100.

GORGONIA, in *Natural History*, a name given by some writers to *CORAL*, on occasion of its supposed change from a soft substance to an absolute stone, on being brought out of the water into the air; but this is known now to be a fabulous opinion, coral being as hard while growing to the rocks, as when it has been ever so long out of the sea.

The *gorgonia* are of a genus of *ZOOPHYTES*, which formerly were called *coralliphytes*, and are known in English by the names of sea-fans, sea-feathers, and sea-whips. Dr. Linnæus and Dr. Pallas consider them as of a mixed nature in their growth, between animals and vegetables; but Mr. Ellis has clearly proved, that they are true animals of the *POLYPS* kind, growing up in a branched form resembling a shrub, and in no part vegetable. They differ from the fresh water polype in many of its qualities, and particularly in producing from its own substance a hard and solid support, serving many of the purposes of the bone in other animals. This is formed by a concreted juice thrown out from a peculiar set of longitudinal parallel tubes, running along the internal surface of the fleshy part: in the coats of these tubes are a number of small orifices, through which the effusive liquor exudes, and, concreted, forms the layers of that hard part of the annular circles, which some, judging from the confidence rather than the texture, have erroneously denominated wood. The surface of the *gorgonia* is composed of a kind of scales, so well adapted to each other as to serve for defence from external injuries: and the flesh, or, as some have called it, the bark or cortex, consists of proper muscles and tes-

sons for extending the openings of their cells; for sending forth from thence their polype suckers in search of food; and for drawing them in suddenly, and contracting the sphincter muscles of these fleshy cells, in order to secure their tender parts from danger and also of proper secretory ducts, to furnish and deposit the offensive matter that forms the stem and branches as well as the bafe of the bone. Mr. Ellis affirms, that there are ovaries in these animals, and thinks it very probable, that many of them are viviparous. Phil. Transact. vol. lvi. part i. art. 1. See *CORALLINE*.

GORGONEI fountains, an affected term used by some of the writers in chemistry, to express those springs of waters which turn things into stone. We have several springs in England, which cover over things with a stony matter, without introducing it into their inner structure; but there are very few certain instances of waters, which at this day absolutely petrify wood, that is, fill its pores with true stony matter. The famous water of Lough Neagh, in Ireland, is much disputed by some as to its having this quality, and many fruitless experiments have been made in attempting to prove that it has.

GORGONEUM, *Gorgones*, in *Antiquity*, a kind of masque used on the ancient theatre to represent hideous and frightful figures, in imitation of the Gorgons. Mem. Acad. Inscript. tom. v. p. 184.

GORGONIUM, in *Botany*, a name given by some authors to the common eryngium or cryngo, the roots of which we use candied.

GORGONS, in *Antiquity and Mythology*. Authors are not agreed in the account they give of the *Gorgons*. The poets represent them as three sisters, whose names were Stheno, Euryale, and Medusa; the latter of whom was mortal, and having been deflowered by Neptune, was killed by Perseus; the two former were subject neither to age nor death. They are described with wings on their shoulders, with serpents round their heads, their hands were of brass, and their teeth of a prodigious size, so that they were objects of terror to mankind. After the death of Medusa, her sisters, according to Virgil, were appointed to keep the gate of the palace of Pluto.

Melampus pterota variorum munda ferarum—

GORGONES, Harpiaeque—

Diodorus Siculus will have the *Gorgons* and Amazons to have been two warlike nations of women, who inhabited that part of Libya which lay on the lake Tritonides. The examination of these female nations was not effected till Hercules undertook and performed it.

Pausanias says, the *Gorgons* were the daughters of Phorcus, after whose death Medusa, his daughter, reigned over the people dwelling near the lake Tritonides. The queen was passionately fond of hunting and war, so that she laid the neighboring countries quite waste. At last, Perseus having made war on them, and killed the queen herself, when he came to take a view of the field of battle, found the queen's corpse so extremely beautiful, that he ordered her head to be cut off, which he carried with him to show his countrymen, the Greeks, who could not behold it without being struck with astonishment.

Others represent them as a kind of monstrous women, covered with hair, who lived in woods and forests. Others, again, make them animals, resembling wild sheep, whose eyes had a poisonous and fatal influence. For a further account of them, see *Mem. Acad. Inscript. vol. iv. p. 72. seq.* See *Medusa caput*.

GORSE. See *FUNZEE*.

GOSHAWK, in *Ornithology*, the English name for the accipiter of *falco palmarum*, a very large hawk, which preys on pheasants, geese, and hares, and is remarkable for the shortness of its wings.

It is larger than the common buzzard, but of a longer and more elegant form. The bill is blue towards the base, black at the tip; the cere is a yellowish green; over each eye is a white line, and on the side of the neck a bed of broken white; the head, hind part of the neck, back, and wings, are of a deep brown colour; the breast and belly white, beautifully marked with numerous transverse bars of black and white; the tail is long, of a brownish ash-colour, marked with four or five dusky bars placed remote from each other. The legs are yellow; the claw of the hawk and that of the inner toe very large and strong. This bird breeds in Scotland, and builds its nest in trees. Ray and Pennant.

GOSLINGS, the name given to young geese.

GOSPEL, a history of the life, actions, death, resurrection, ascension, and doctrine of Jesus Christ.

The word is Saxon, and of the same import with the Latin term *evangelium*, or the Greek *euangelion*, which signifies glad tidings, or good news; the history of our Saviour being the best history ever published to mankind. This history is contained in the writings of St. MAT

THEW,

THEY, ST. MARK, ST. LUKE, and ST. JOHN; who from thence are called Evangelists. The Christian church never acknowledged any more than these four Gospels as canonical; notwithstanding which, several apocryphal gospels are handed down to us, and others are actually sold.

GOSSAMER is the name of a fine filmy substance, like cobwebs, which is seen to float in the air, in clear days in autumn, and is more observable in stubble-fields, and upon furze and other low bushes. This is probably formed by the flying spider, which, in travelling the air far and fast, shoots out these threads from its anus, which are borne down by the dew, &c.

GOSSAMPINDUS, a name given by Pliny and the ancients to a tree growing in the East Indies, which produced a sort of cotton, the threads of which were too short to be spun or carded; so that it served only for the flumings of beds and the like, for which it was very proper, being very light and soft. It was in some esteem in medicine also, to recall the heat and spirits into parts to which it was applied. It is called by *Pilocotton longiora*, the wool tree, and had its ancient name from the words *gossam*, cotton, and *pindu*, the pine-tree, being somewhat like the pine in external appearance, yet bearing a sort of cotton.

GOSSYPIUM. See **COTTON**.

GOTHIC, or **GOTHICK**, something that has a relation to the Goths, an ancient people, originally inhabiting that part of Sweden called Gothland; whence they spread themselves over Greece, Dalmatia, Bulgaria, Italy, Spain, &c.

We say, the *Gothic manner*; *Gothic ignorance*, the tyrant Maximian was of *Gothic race*.

It has been a general opinion, strenuously maintained by Curceus and Pellerin, and adopted by Mallet in his Northern Antiquities, that the *Gothic* and *Celtic* nations were the same; but the ingenious English translator of Mr. Mallet's work has produced a variety of testimonies from ancient authors to prove that the *Celtic* and *Teutonic* or *Gothic* nations were, *ex origine*, distinct, and that they differed considerably in person, manners, laws, religion, and language. The former were the ancestors of the Gauls, Britons, and Irish; and the Germans, Saxons, and Scandinavians derived their origin from the latter. The *Celtic* tribes were probably the first that travelled westward; and the *Goths*, or *Getae* of the ancients, who emigrated at different times from the eastern countries after they might borrow some of their opinions and practices, which will account for the resemblance that has been observed between them, without admitting that they were descended from them, or that they should be considered as the same people. In the same way we may account for those reliques both of *Celtic* and *Gothic* superstitions which are discernible in Gaul and Britain and many other countries, the inhabitants of which derive their descent equally from the *Celts* and *Goths*, who were at different times masters of these kingdoms, and whose descendants are now blended together: thus, the first inhabitants of Gaul and Britain being of *Celtic* race, followed the Druidical superstition. The ancient Germans, Scandinavians, &c. being of *Gothic* race, professed that system of polytheism which was afterwards delivered in the *EDDA*; and the Franks and Saxons, who afterwards settled in Gaul and Britain, being of *Gothic* race, introduced the polytheism of their own nation, which was in general the same that prevailed among all the other *Gothic* or *Teutonic* people. With regard to the *Gothic* and *Celtic* languages, they are radically different from each other; and from these two mother-tongues the following particular languages are severally derived: from the *Gothic* are derived the old Saxon or Anglo-Saxon, the *Francic* or *Franco-thotic*, and the *Cimbic* or old Icelandic; of the old Saxon are formed the English, the broad or Lowland Scotch, the *Belgic* or Low Dutch, and the *Frisic* or *Friseland* tongue; from the *Francic* proceed the *German* or High Dutch, the *German* of Swabia, and the *Swiss*; and the *Cimbic* is the immediate source of the Icelandic, Norwegian or Norse, Danish, and Swedish. From the *Celtic* language are derived the ancient *Gaulish*, the ancient *British*, from which proceeded the *Welsh*, *Armorican* or *Brit-Bretagne*, and *Cornish*; and the ancient *Irish*, from which sprung the *Irish*, *Erse* or Highland Scotch, and the *Manx* or language of the Isle of Man. See the preface and notes to the English edition of Mallet's Northern Antiquities, 1770. See **TEUTONIC**.

GOTHIC BIBLE. See **BIBLE**.

The *Gothic* version of the four Gospels, first printed at Dort in 1665, was published at Oxford in 1750, by Mr. Lye: this edition was designed and prepared by Benzilius, archbishop of Upsal, with a Latin translation and notes, in which the editor introduced some small varia-

tions, and added a *Gothic* grammar. The ancient manuscript of the *Gothic* version is preserved in the library of the university of Upsal, in Sweden, under the name of the *Calix Argenteus*, or *Silver book*, because the letters, which seem to have been stamped on the vellum leaves with hot metal types, are of silver, except the initials, which are gold. Another fragment of this curious version, containing part of the Epistle to the Romans, has been since discovered in the library at Wolfenbuttel, and published a few years ago in a splendid volume in quarto, by the Rev. P. A. Knittel, archdeacon of Wolfenbuttel.

GOTHIC CHARACTER or **WRITING**, is a character or manner of writing which, in the main, is the same with the Roman, only that it is very full of angles, turns and bendings, especially at the beginning and ending of each letter.

The manuscripts in *Gothic* characters are not very ancient. Ulfilas, bishop of the Goths, was the first inventor of the *Gothic* characters, and the first that translated the Bible into the *Gothic* tongue.

The letters used in the *Gothic* gospel are twenty-five in number, and formed with slight variations from the capitals of the Greek and Latin alphabet.

The Runic characters are also frequently called *Gothic* characters. See **BLABLION**, *De Re Diplomatica* lib. I. cap. 2. But they who take the *Gothic* characters to be the same with the Runic, are mistaken; as is shown by Ol. Wormius, Julius in his preface to the Gospels wrote in *Gothic* letters, and Dr. Hicks on the Runic Tongue.

GOTHIC ARCHITECTURE is that which derives from the propriety, character, &c. of the antique.

The *Gothic* architecture is frequently very solid, heavy, and massive, and sometimes, on the contrary, exceedingly light, delicate and rich. An abundance of little whimsical ornaments are its most usual characters.

Authors distinguish two kinds of *Gothic* architecture; the one ancient, the other modern. The ancient is that which the Goths brought with them from the North, in the fifth century; the ancient style in this manner were exceedingly massive, heavy, and simple. The characters of this style are thick and solid walls are very thick, generally without buttresses; the arches, both within and without, as well as those over the doors and windows, semi-circular, and supported by very solid or rather clumsy columns, with a kind of regular base and capital; in short, plainness and solidity constitute the striking feature of this method of building. However, the architects of those days, when this style prevailed, did not wholly neglect ornaments.

Those of the modern *Gothic*, or, as it should rather be called, the *ARABESQUE*, was introduced about the seventh century, and run into the other extreme, being light, delicate, and rich to a fault; whence Westminster-abbey, the cathedral of Litchfield, the cross of Coventry, &c. The last kind continued long in use, especially in Italy; viz. from the thirteenth century to the reformation of the antique building in the sixteenth. All the ancient cathedrals are in this kind.

The inventors of the *Gothic* architecture thought, no doubt, they had far surpassed the Greek architects; a Greek building has not a single ornament but what adds a beauty to the whole: the parts necessary to sustain or shelter it, as the columns, cornices, &c. derive all their beauty from their proportions; every thing is simple, measured, and restrained to the use it is intended for; no daring out-of-the-way strokes; nothing quaint to impose on the eye; the proportions are so just, that nothing appears very grand of itself, though the whole be grand. On the contrary, in the *Gothic* architecture, we see huge vaults raised on slender pillars, which one would expect every minute to tumble down, though they will stand for many ages. Every thing is crammed with windows, towers, columns, figures, &c.

The marks which constitute the character of modern *Gothic* or Saracenic architecture, are its numerous and prominent buttresses, its lofty spires and pinnacles, its large and ramified windows, its ornamental niches or canopies, its sculptured fountains, the delicate lace-work of its fretted roofs, and the profusion of ornaments thrust indifferently over the whole building: but its peculiar distinguishing characteristics are, the small clustered pillars and pointed arches, formed by the segments of two intersecting circles; which arches, though last brought into use, are evidently of a more simple and obvious construction than the semi-circular arches. The first appearance of this style of building in our country was towards the latter end of the reign of Henry II. In the reign of Henry III. it seems to have attained a complete footing: the present cathedral church of Salisbury, which is entirely in this style, was begun early in this reign, and finished in the year 1258. From the reign of Henry VIII. or the close of that of Henry VII. the

Gable architecture began to decline, and was soon after supplanted by a mixed style, wherein the Grecian and *Gable* are blended together. The Roman or Grecian architecture did not prevail in England till the time of Inigo Jones, yet there were some earlier specimens of this style, particularly *Somerley-house* in the Strand, built in 1594, but lately pulled down, and rebuilt.

Most of the great buildings of queen Elizabeth's reign have a style peculiar in themselves in which, though much of the old *Gable* is retained, and great part of the new style is adopted, yet neither predominates; while both, thus indistinctly blended, compose a fantastic species, hardly reducible to any class or name. One of its characteristics is, the affluence of large and lofty windows. See *ARCHITECTURE*.

Gable where it is any round pillar in a *Gable* building, either too thick or too small for its height.

There are some found even twenty diameters high, without other diminution of swelling.

Gable *arch*. See *MISAL*.

GOTTORGINE, in *Ichthyology*, the name of a small fish common in the Mediterranean, and brought to market at Rome, Venice, &c. It has no scales, but is soft and fibrous to the touch, large toward the head, and smaller toward the tail, and of a fatted shape. Its colour is mottled with olive colour and a brownish red, disposed in lines running half-length, and parted by other lines of a pale blue. It is usually of about six or seven inches long. It has no swimming-bladder, and the anus is situated nearer the head than the tail. See *ADONIS* and *PERCIFORMIS*.

GOUANIA, in *Botany, a genus of the *polygamia mascula* class. This genus bears hermaphrodite and male flowers; the hermaphrodite have a calyx divided into five segments; no corolla; five anthers; and a trifid style; the fruit is composed of three parts; the male resemble the former, but has neither germin nor stigma.*

GOUD, or **GAUD**. See **WELD**.

GOVERNMENT, a quality or office which gives a man power or right to command or rule over a place, a city, a province, a kingdom, or the like, either supremely or by delegation.

Government is either general and supreme, as that of a whole kingdom, empire, foreign state, &c. or particular and subordinate; which, again, is subdivided into civil, military, and religious.

Our cities, corporations, and boroughs, are usually governed by mayors, with aldermen and common-councilmen.

GOVERNMENT is also used for the country, city, or place to which the power of governing or commanding is extended.

There are thirty-eight governments by provinces in France, independent of each other. Beside these, there is another division into governments, called *grand governments*, whereof there are twelve, viz. those of the life of France, Burgundy, Normandy, Brittany, Picardy, Dauphine, &c. which are not proper provinces, commanded each by its separate governor, but rather to many classes of governors or governments, conferred for the better and easier regulating the state, &c. of many governors, bailiffs, provosts, &c. were obliged to assist at the holding of the general estates.

GOVERNMENT, again, is used for the manner or form of government, i. e. for the policy of a country, state, &c. In this sense, governments are divided into MONARCHIES, ARISTOCRACIES, and DEMOCRACIES.

The government of France is monarchical, that of Venice, aristocratic, and that of the United Provinces, democratic; the government of England is every being monarchical, aristocratic, and democratic, all in one.

Civil government and society originate in the wants and fears of individuals, who, being naturally free, equal, and independent, associate together, either by express or tacit consent, for the mutual preservation of their lives, liberties, and estates, on this fundamental principle, that the whole should protect all its parts, and that every part should pay obedience to the will of the whole. However the several forms of government, that now subsist, actually began, there is and must be in all of them a supreme, irresistible, absolute, uncontrolled authority, in which the *vera summi imperii*, or the rights of sovereignty, reside; and this authority is placed in those hands, whether, according to the opinion of the founders of such respective laws, either as the result of collected from their own observation, the qualities requisite for sovereignty, viz. wisdom, goodness, and power, are the most likely to be found.

Individuals unite for mutual protection and benefit; and, therefore, the legislative and executive authority of government, originally derived from themselves, should be invariably directed to no other end but their safety and

welfare; and that form of government is most eligible, which is best adapted to these purposes. Locke declares himself of opinion, in his fragments De Rep. lib. ii. "An optimum constitutio empiricum, que ex istis est, melior illis, regali, quam illi populari, sit melior sit." Of this kind is the British constitution, which lodges the executive power of the laws in a single person, and the legislative in three distinct powers, entirely independent of each other; viz. the king; the lords spiritual and temporal, forming an aristocratical assembly; and the house of commons, freely chosen by the people, which renders it a kind of democracy; and each branch of this aggregate body, viewed by different views, and attended to different interests, is armed with a negative power, sufficient to repel any innovation which it shall think expedient or dangerous. "Nobis can endere, or hurt the constitutional government of Britain, but destroying the equilibrium of power between one branch of the legislature and the other; for if ever it should happen that the independence of any one of the three should be lost, or that it should become inferior to the views of the other two, there would soon be an end of our constitution: the legislature would be changed from that which was originally set up by the general consent and fundamental act of the society; and such a change, however effected, is, according to Mr. Locke, at once an entire dissolution of the bonds of government, and the people are thereby reduced to a state of anarchy, with liberty to constitute to themselves a new legislative power." Locke on Government, book ii. chap. ix. Blackst. Com. vol. i. Intro. See *LAW*, *LIBERTY*, *PARLIAMENT*, &c.

GOVERNMENT, in *Grammar*, is understood of that construction of nouns and verbs, wherein they require some attention to be made in others joined or connected with them.

Construction is divided into two parts; that of CONCORD, and that of GOVERNANCE, called also REGIMEN.

GOVERNOR, an officer vested by a king, or sovereign prince, with the command and administration of a province, place, &c.

A governor represents the king; and not only commands the garrison, troops, &c. but the citizens, &c. A governor of a fortified place was anciently required to hold out three months, before he surrendered.

GOVERNOR is also frequently used for a president, or superintendent.

Thus we say, the governor of the bank; the governor and directors of the South Sea company; the governor of an hospital, &c.

GOVERNORS of the ship at Glasgow, are officers appointed to take care of, and regulate the poor and trained schools belonging to the royal navy. Vide 22 and 23 Car. II.

GOUSE. See **GOAT**.

GOUGE, an instrument used by divers artificers, being a sort of round, hollow chisel, serving to cut holes, channels, grooves, &c. in wood, stone, &c.

GOUIMA, in *Astronomy, the name given by the natives of the island of Sumatra to the Samian earth, called *terra Lemnia* by the old writers.*

GOULD, *Accordia*, in *Botany*, a genus of the *monocotyledon* class. Its characters are these: It has male and female flowers, which are bell-shaped, adhering to a bell-shaped enlargement of one leaf, and composed of one petal, divided at the top into five parts. On the same plant; the male flowers have three stamina, which are connected at the extremity, but are distinct at their base; the female flowers have a large germen, which becomes a large fleshy fruit, having three soft membranaceous cells, which are filled, including two rows of seeds, which are horsed. Miller reckons five species, and Linnaeus fix, one of which is the common pompan of peasants, and another the calyx of *HELIOPSY*.

Goulds are esteemed cooling and diuretic, are used in emulsion, and effected good in fevers, and all disorders arising from the acrimony of the blood or humors. Emulsion of these, and the other cold seeds, are cooling, and are generally used to take off transients occasioned by biliousness but those prepared from sweet almonds are more universally preferred.

GOULD, SIMON. See **COLOMBUS**.

GOULD, ISRAEL. See **GABRIEL**.

GOULD, JOHN. See **BARBAR**.

GOULD-MOUSE, the English name of a species of weasel found in the intestines of several animals. It has this name from its resembling the feet of the *gould* in figure.

GOURDY *localis*. See **GRAPE**.

GOURDY *torreyi*, in *Natural History*, a name given by the people of the East Indies to a kind of opuntia of a deep yellow colour, veined with red in several places, and in some with white. It is found principally at the bottoms of mountains. They calcine it several times, and afterwards

afterwards give it internally in intermitting fevers, and use it externally in ointments for the itch.

GOUT, Gout, a French term, for what the Italians call *gotta*, and we *GOUT*.

GOUT, Arthritis, in Medicine, a painful disease, occasioned by a flux of sharp humours upon the joints of the body.

Some physicians define the *gout*, an inflammation, swelling, and painfulness of the joints. Its origin is usually attributed to wine, venery, glutony, idleness, and grief, or any violent perturbation of the mind. Intemperance and indolence are the principal causes of the *gout*; however, a passion in those who are subject to it may be occasioned by immoderate, too free a use of acid liquors, night-sweating, variation and uncleanliness, an obstruction or defect of any of the customary discharges, at the menfes, sweating of the feet, perspiration, &c. The predisposing cause is the magnitude of the lacteals, and the streightness of the small vessels, particularly the peristomium. The prostatic humours, says Dr. Hales, are most apt to ferre and cause inflammatory obstructions in the extremities of the body, as in the feet and hands, where the progressive force of the blood is the least, as being farthest from the heart. And when these humours fix in the trunk of the body, they are more apt to settle in the stomach than in the guts; because in the former they have at much greater length of capillary vessels to reach the motion of the blood, as half the circumference of the stomach is greater than that of the guts; for the arteries of the stomach do not enter its coats on one side only, as those of the guts do, but it is supplied with blood by arteries which enter, some on the upper hand, some on its lower side; their converging branches communicating about the middle of the dist. Hales's Statical Essays, vol. ii. p. 108, ed. 1769.

The *gout* is supposed to arise from two causes; a redundancy of humours, and a weakness of the joints. Its proper seat is in the limbs, not in the trunk of the body; in the latter case it frequently proves mortal; not in the former.

Malgrave makes the apoplexy a *gout*, because it arises from the abundance of pituita, or phlegm. According to this redundant pituita throws itself on the lungs, the liver, or any other part, it makes, according to him, an apopleptic *gout*, a *gout* of the liver, of the lungs, of the spleen, &c. The *gout* may be considered as a painful, periodical, and critical paroxysm, tending to free the body of an offensive or corrodive matter, by throwing it upon the extremities, lessening it out insensibly, or comminuting it so as to render it harmless, or capable of circulating freely along with the juices; till by collecting again, gradually increasing, or separating from the blood, it causes another paroxysm.

As this disease receives different appellations, according to the places it affects, the following distinctions will be found necessary, to prevent confusion on this head.

Arthritis is a word very differently understood by different authors, some expressing by it only what we call the *gout*; others making it the general name of that and many other diseases of the same nature and origin, and distinguishing that particular species of it which we call the *gout*, by the term *podagra*. Stahl, and from him Junker, define the *arthritis* to be a spastic affection of the joints in any part of the body, afflicting the patient with a violent and lasting pain, and never coming to that salutary end, which nature seemed to intend by her motions in it.

The *podagra* in particular is thus defined to be a spastic and painful affection of the foot, taking its origin from a congestion of blood, which should have been voided by the hemorrhoidal vessels, and which finding no means of evacuation there, becomes very painful in its motions, and growing into a habit afterwards, recurs on any slight occasion.

When the *arthritis* is taken in its general sense, it comprehends several diseases distinguished by their several specific names, as the hemiplegia, the spurious pleurisy, the flatulency, the chiroagra, the gonagra, and finally the podagra, or *gout* in the feet.

Some authors take the word *arthritis* in a more specific sense than this, and yet distinguish it sufficiently from the *podagra*; these express by it these spastic affections which happen in the upper limbs and parts of the body; it is then made of the same genus with the *podagra*, and distinguished from it, as one species from another, by the following particulars.

The *arthritis* affects young persons, the *podagra* those more advanced in years. The *arthritis* is naturally the first of these two diseases in persons who have them both; and as people afflicted with it grow into years, it very naturally degenerates into a *podagra*. This is a distinction of some very judicious authors; yet in reality the several appearances of the *arthritis*, as taken in its most

general sense, differ no otherwise than as to the parts they affect, and the times at which they happen; for they all agree in their essential conditions and general causes. The true *arthritis* is however to be carefully distinguished from what is called the *arthritis* regarding wandering, simple, or torpid *arthritis*. This very evidently flies from one part of the body to another, and changes places from the feet to the thorax, from thence to the hips and so on. Junker's Conf. Med. p. 682. The rheumatism and *arthritis* are diseases also not greatly different from, but properly subordinate to one another, and as light *arthritis* is very often called a fit of the rheumatism. The rheumatism is no other than a stagnation of the mals of blood about particular parts of the body, taking its origin from a copious concretion of the blood, particularly directed by nature to that part. The rheumatism has its seat in the muscular parts of the body, the *arthritis* principally affects the joints of the several limbs. The rheumatism naturally precedes the *gout*, and very often degenerates into it; it is even certain that the rheumatism and *arthritis* often are complicated together. Simple congestions and conmutations of the blood differ extremely from the *arthritis*; first in regard to their effects, for they usually terminate in an eruption of the blood by some means, but the *arthritis* never arrives at that end.

Secondly in their duration, for they are usually terminated some way within a very short period; but this disease is of very long and terrible duration. They differ, thirdly, in regard to the parts they affect: the simple congestions affect the internal parts and the blood-vessels; but the *arthritis* affects the external, and the muscular fibres. Finally, they differ out in regard to the events; for the simple congestions bring on inflammations and ulcerations, but the *arthritis* contrains and extenuations of the limbs.

The signs of the flatulency are a vehement and excruciating pain in the hip, which remains a long time, and is felt principally in the tendons, and in the junctures of the bones. This spasm violently affects the muscles of the whole side, that the patient is compelled to walk in a crooked posture.

The other *arthritis* complaints, as the hemiplegia, &c. are described under their several heads, and the general method of cure is the same in all of them.

The *gout* is either *regular* or *irregular*. *Regular*, when it appears to be seated in the extremities of the body, when it chiefly and immediately affects the tendons, nerves, membranes, and ligaments of the body, about the joints, returns at stated periods, and with a gradual increase and decline of the symptoms. *Irregular*, when the paroxysm are frequent, and uncertain; when the symptoms vary, or happen promiscuously, and the disease appears to be seated in the internal parts of the body, as the stomach, brain, &c. leaving the extreme parts, as the hands, feet, &c. free from pain. According as different parts are affected by this disorder, it goes by several different names: when it seizes the feet, it is called *PODAGRA*; when the knees, *GONAGRA*; when the hands, *CHIROAGRA*; and when the hip-joint, *SCIATICA*.

Sometimes it attacks the whole body at the same time, and then it is called the *general* or *universal* *gout*.

The immediate cause of the *gout* appears to be an alkaline, or acrimonious matter in the blood; which being separated from it at particular times, falls upon the joints, but most frequently upon the feet and hands; which, if it be repelled, or if the blood be overcharged therewith, so that a crisis cannot be procured in the extremities (as generally happens in old age), it falls upon the nobler parts, and then produces the irregular *gout*: but it is the tonica cellularis of the affected parts, that is the immediate seat of the disease.

Dr. Stevens endeavours to prove the *gouty* humours to be rather of an alkaline than acid nature.

Dr. Cajotanus Tacconius tried many experiments with the mucilages of the joints of brutes, and of men, both found and *gouty*, in order to discover whether the *gouty* matter is acid or alkaline, and concludes, that its matter is sometimes of the one, and sometimes of the other nature. If the *gout* produces no *spots*, or *knots*, or does it very slowly, and especially if it is attended with redematous swellings, he pronounces it to depend on an alkaline humour, but if the *knots* are large, and quickly formed, it is owing to an acid.

Dr. Hunter thinks that the viscous matter is separated by small arteries, and thrown upon the membranes or cuticulae, and that there is more or less separated as the *viscous* is greater or less; and that in the *gout* there is a redundancy of bony matter, which probably forms the chalk floors.

Dr. Cheyne says, that the chief reason why the *gouty* matter

matter generally fixes on the joints is the pressure there from the head of the bones, which lessens the capacity of the small vessels, to which may be added the insalubrity of the glands in the joints, and the natural coldness of these parts, occasioned by the distance from the heart. The earthy particles, whose acrimony occasions the *gout*, are conveyed into the *tunica cellularis* of the ligaments, tendons, &c. where the vessels are less than in the bellies of the muscles and fleshy substances, and retained in them; and as they are more or less acrimonious, produce greater or less heat, and cause that inflammatory appearance and intolerable pain, which accompany this disorder; but the parts affected soon losing their sensibility, the pain abates, and the offending matter is again returned into the circulation, and discharged out of the body through the pores.

It is observed, that women, children, and young men, are seldom troubled with the *gout*, unless it be hereditary; and that it rarely attacks before the patient is thirty-five or forty years old, and sometimes not till the decline of life; that the complaint are more subject to it than those who are spare and lean; that the pain increases towards night, and decreases towards the morning; that the longer the intervals between the paroxysms, the more severe they prove, and the longer they generally continue. The disease usually returns twice a year; viz. in the spring and autumn; and, in the latter, the paroxysm is sometimes two or three months before it comes to a period; though its duration is, at other times, not above three or four weeks.

These are called *cardiac paroxysms*, to distinguish them from others of less duration, which happen between the spring and autumn. The more highly coloured the wine, and the less ferment it deposits, the farther is the disease from the force of *cardiac*, as it is termed. According to the violence and continuance of the fever, the paroxysm proves more or less severe. In constitutions much broken or disordered with the *gout*, there are usually gross or chalky concretions formed in the joints of the fingers, or toes, and thence translated to the viscera; which case is often attended with irregular, frequent, and short paroxysms, in the extremities, or in the decline of life, when the usual fits do not happen; or if the *gout* never be suddenly repelled from the extremities by an improper regimen, or medicines, it usually seizes the internal parts, and frequently the stomach, head, intestines, &c. causing want of appetite, reaching to vomit, indigestion, a coxertia, the jaundice, asthma, diarrhoea; and, at last, to obstruct the fine capillary, nervous tubes (especially those of the stomach and brain), as, possibly, to hinder the flux of the animal spirits; upon which death suddenly ensues.

Sydenham gives us an accurate history of a regular fit of the *gout* in the feet: it begins towards the close of January, or beginning of February, without the least previous notice; except, perhaps, a crudity, or dyspepsia, for some weeks before-hand; with a sort of windy intumescence, a heaviness of the body, and a detestation of solids, which continually increase, till at last a paroxysm breaks out, being preceded, some days, with a sort of stupor, and a sensible descent of the fluids through the flesh of the thighs, with some spasmodic symptoms. The day before the paroxysm, the patient's appetite is very free, and there is a slight pain in passing the urine; an hour or two after midnight he is waked by a pain, commonly in his great toe, sometimes in the heel, ankle, or the calf of the leg, not unlike the pain felt upon a dislocation of the foot bones; with a sense as if water was sprinkled on the part affected. This is succeeded by a chilliness, and some approach to a fever: the pain, in the mean time, which at first was more remote, gradually increases, and is proportion to the chilliness above. By night it is arrived at its height, and settled about the ligaments of the bones of the tarsus and metatarsus, where it sometimes resembles a violent tenderness, and sometimes a laceration of these ligaments; sometimes the biting or gnawing of a dog, or a gnawing, or carabation. Then the part affected has such an exquisite sense, that it cannot bear the weight of the linen, nor even the flaking of the room occasioned by a person's sleeping. Hence, a thousand vain endeavours are got case, by changing the posture of the body, the position of the foot, &c. till about two or three o'clock in the morning (the force of nycthemeron from its access) when a remission is first perceived, the morbid matter being by this time tolerably digested, or even dissipated. The patient finds his pains much abated, but the part is inflamed, swollen, and covered with a little moulure. Towards morning he drops asleep, and generally falls into a gentle breathing sweat. A few days after this the other toes again undergoes the same fate; sometimes both are attacked from the first. From the time it has

seized on both legs, the symptoms become more irregular and precarious, both as to the time of invasion, and the duration thereof. But this still holds, that the pain recurs in the night, and remains again in the morning. A series of these fits, alternate access, &c. constitutes a fit of the *gout*, which lasts longer or less according to the age and strength of the patient, the season of the year, and the disposition of his body to the disease. The paroxysm, however, grow milder every day, till at length the disease is carried off by perspiration, urine, and the other evacuations. In strong people, and those who have had it often, fourteen days are a moderate fit; in old people, and those long used to it, it will hold two months; though the tenderness and swelling in severe fits will sometimes remain longer, and cause an uneasiness upon motion; and any violent exercise will bring it on again. For the first fourteen days the patient is usually colic, a loss of appetite, a chilliness towards evening, and a heaviness and uneasiness even of the parts not affected, attend the whole paroxysm. As it goes off, he is seized with an intolerable itching, especially between the fingers; a suffer falls off, and his toes scale, as if he had drunk poison.

Such is the course of a regular *gout*; but when through improper treatment it is disordered, or prolonged, it seizes the hands, wrists, elbows, knees, and several other parts; sometimes distorting the fingers, and taking away their use; sometimes generating suppurative concretions, or knots about the ligaments of the joints resembling chalk, or crab's eyes; sometimes raising a whitish, inflammable tumor, almost as big as an egg, about the elbow, &c. See NODI, TORMI, &c.

It may be added, that where a person has laboured under the *gout* for many years, the pain is scarcely lessened each paroxysm, till at length it becomes rather an aneurism than a pain; hence has reduction of the great Symplicium, *Detur in hoc morbo aneurismum et scurra phlegmonum*.

Method of cure. The *gout* is ranked among the number of incurable diseases: in effect, we have no thorough and assured remedy yet discovered for it, though that now obtain is little more than palliatives; they tend to allay the pain, to diminish it for a time, but not to extirpate it. Bleeding, and purging, and oily hordeums, are to be used with great caution. Emetics, according to Picaud and Krammer, may do good in the beginning of the disease, upon the whole, nothing, in Sydenham's opinion, proves of more service than digestives, or medicines which strengthen the stomach, and promote digestion; as, angelica root, cinch. camp. the theriac. Andromach. the Jesuit's bark, and antiscorbutics: these are chiefly to be administered in the intervals between the paroxysms. Maffræ, however, recommends, internally, repellents, and principally calomel externally, emollients of gum, cayan, or exorcise, or cephalic with Burgundy pitch, or the green fear-cloth, commonly called *let-top*, &c. Yet Dolens affirms, that repellents do more harm than good; and gives us the following recipe, as more than equal to all others. R. Confect. hamech. 3j. pulv. jalap. ʒi. extract. nifol. libris. ʒij. libarg. aur. ʒij. lipo. an. timon. ʒij. f. elect. cath. ʒij. ol. olive. q. s. cern et picea parant. f. f. 2. An emollient to be laid on the joint affected, till the pain, and the morbid matter, be driven away.

According to some, the material cause, which is a phlogistic habit, is to be removed by bleeding at proper times, and by applying leeches to the hæmorrhoidal veins to promote a discharge that way; and in persons of a moist habit, cupping is very proper. After this the evacuations of the prime viæ, especially such as are of a bilious nature, are to be abridged, and gently carried off, as they always are the occasion of all specific pains being greatly exasperated. The digestive sale, such as *carbon. tartarum. ardens. depuratum*, and the like, are very good abstersives; and the proper method of evacuating the matter is by gentle laxatives, such as purging draughts of lemon and rhubarb, with a little soluble tartar. Clusius's sale, or the common purging sale, called Epsom sale, succeeds also very well, and great service is done by the medicated wines, impregnated with the abstersive, diuretic, and purging ingredients. A bilious or uneasiness in the stomach may be removed by cardus or camomile tea, or by a little peccavola. Venous promote perspiration, and in the circumstance now mentioned, no danger need be apprehended. The violent emotions of the blood, and its sulphureo-saline acrid quality, are to be attenuated, and the rigors of the solids softened and taken off. This is excellently done by nitrous medicines, with saline abstersives; and in the more robust habit, sometimes the stronger acids are necessary. After this nature is to be assisted in making an equal and regular distribution of the humours. This is to be done in persons of choleric habits,

A total milk and feed diet will, it is said, cure the *gout*. See Cheyne's Nat. Merit. of Curing, p. 266.

Dr. Dover says, a *gouty* patient will be free in two or three hours at farthest, after taking a dose, from forty to seventy grains, of the following powder: take salt-petre, and tartar vitriol, each four ounces; put them into a red-hot mortar, stir them with a spoon till they have done flaming, then powder them very fine, and after that mix in an ounce of opium; grind those to powder, then mix it with an ounce of the powder of ipecacuanha, and as much of the powder of liquorice. This is to be taken going to bed, in a glass of white wine posset-drink, covering up warm, and drinking a quart or more of posset drink while sweating.

The doctor is also of opinion, that Myrsch's chair of vitriol often taken, though it may cause pain for some time, yet much certainly dissolves the *gouty* matter in the end. Med. Ess. Edit. b.

The *gout* powder of the duke of Portland, who brought the receipt with him from Switzerland a few years ago, has been much recommended both for this disorder and the rheumatism. The manner of preparing it is as follows: take of the root of aritholoba rotunda, or birthwort, and of gentian, and of the tops and leaves of germander, green spina and centaury, dried, powdered, and sifted, equal weights; mix them well together, and take one dram of this mixed powder every morning falling in a cup of wine and water, broth, tea, or any other liquid; keep falling an hour and a half after it; and continue this course for three or four months without interruption; then diminish the dose to three-fourths of a dram for three months longer, then to half a dram for six months more, taking it regularly every morning, if possible. After the fifth year it will be sufficient to take half a dram every other day. As this medicine operates infusibly, it must be persisted in for two years or more, and in the use of it the patient is not confined to any particular diet, so that he lives soberly, and abstains from those meats and liquors that have always been accounted pernicious to the *gout*, as champagne, drams, high lunces, &c. Dr. Cullen has shown, that the *distillation* of Calvus Aethiops, and the *acidities* or *dephlogestations* of Acetum, were the same medicine, and are the old names for the duke of Portland's powder. This medicine is at present in high esteem with many; but an indiscriminate use of it in all cases may bring it into disrepute. Med. Obs. Sec. vol. 1. art. 14. p. 126, &c.

When the fits are thoroughly off, bleeding should never be omitted, spring and autumn, and in people of faculent habit, cupping upon the parts is often very useful; with women, the menses are to be considered before all things, and brought to their regular periods before any hope of a cure can be hid. In men, the application of leeches to the hemorrhoidal veins is of service, and four times, at least, in the year purging remedies, such as rhubarb, senna, and the like, are to be taken in decoctions, or infusions, mixing with them such things as are known to sweeten the blood. And in the general regimen, a sufficient quantity of weak liquors is to be always drunk, and a moderate exercise of the body is to be kept up. And finally, as the spring and autumn are the times at which the fits of all *arthritis* diseases usually return, it will be proper, by way of prevention, to take at such times decoctions or infusions of salisfras, or the other woods, in the manner of tea, and with them a few moderate doses of some of the nitrous medicines.

Above all things, when a fit is gone off, the occasional causes of its return are to be avoided; these are a too rich diet, the drinking too much wine, an immoderate use of venery, violent emotions of the mind by anger, or other passions, and violent and immoderate exercises; if these are not restrained, the return of *gout* will probably be of very short duration.

The patient should also take a gentle dose or two of the bitter tincture of rhubarb, or some other warm stomachic purge. He should likewise drink a weak infusion of stomachic bitters in small wine or ale, as the Peruvian bark, with cinnamon, Virginian snake-root, and orange-peel. His diet should be light and nourishing, and his exercise regular and gentle. In order to prevent the *gout*, universal temperance and sufficient exercise are of principal importance. Going to bed betimes, and rising early, will be of great use. Night studies, and intense application, late and full suppers, and all strong liquors, especially generous wines and four punch, should be avoided. Beside the course already prescribed, an issue, or perpetual blister, has a great tendency to prevent the *gout*. Bath waters are of great service in promoting digestion, and invigorating the habit. Cheyne observes, that a dram of powdered sulphur, or flour of blunstone, taken regularly in a spoonful of milk, has prevented the fit for many years.

Though there is little room for medicine during a regular fit of the *gout*, yet when it leaves the extremities, and falls on some of the internal parts, proper applications to remove and fix it become absolutely necessary. Mergrove had a high opinion of the acetos. martis in this view. When the *gout* affects the head, the pain of the joints ceases, and the swelling disappears, while either severe head-ach, drowsiness, trembling, giddiness, convulsions, or delirium, come on. When it seizes the lungs, great oppression, with cough and difficulty of breathing ensue. In these cases, the feet must be frequently bathed in warm water, and acrid campham applied to the soles. Blisters on the feet ought likewise to be applied to the ankles or calves of the legs. Bleeding in the feet or ankles is also necessary, and warm stomachic purges. The patient should also be kept warm. When the *gout* attacks the stomach, extreme sickness, vomiting, anxiety, pain in the epigastric region, and total loss of strength succeed. In this case, the milk warm cordials are necessary, as sitting wine boiled up with cinnamon or other spices, cinnamon-water, peppermint-water, or even rum and brandy. The patient should keep his bed, and promote a sweat by drinking warm liquors; and if he be troubled with a nausea, drink camomile tea, or any thing that will make him vomit freely.

When the *gout* attacks the kidneys, and resembles gravel-pains, the patient should drink freely of the decoction of marshmallows, and have the parts inclosed with warm water. An emollient clyster should be administered; and when the pain is violent, twenty or thirty drops of laudanum may be taken in a cup of the decoction.

The approaches of the *gout* should be attentively observed, and this disorder distinguished from all others, lest by an improper treatment the patient should fix lasting head-ach, cough, and pains of the stomach and intestines, and at last fall a victim to this disease, by its attack on some of the more noble and vital parts. Boerhaave's Dom. Med. chap. 36.

Monsieur de Saull being of opinion, that the *gout* depends on the want of perspiration, proposes warm baths, exercise, keeping always warm, and defending from cold; clean cloaths, moderate eating, abstaining from supper, tranquillity of mind, friction and milk diet, as preservatives from it. Garlic being observed by Sanctoerius to increase perspiration, is recommended; as the cortex Peruvianus and steel, in winter. When the stomach is attacked he lets blood at the ankles, and applies epispastics of different kinds to the feet, and then endeavours to procure a general sweat. When the pain is very violent he blisters it, by applying a cloth dipped in liquid laudanum to the painful part, and exhorts the patient to use exercise after this. Medic. Ess. Edit. b.

Cheyne observes, that mercurial venoms are not only proper for the *gout* in the stomach, but that they are absolutely necessary, as well as the mercurial purges, when the *gout* becomes fixed to and permanent in any part, and also when it is dispersed all over the habit like a rheumatism; that these active medicines must first render the humours fluid, which gum guaiacum, with diaphoretic antimony, will afterwards carry off.

GOUT-WORM, in Botany. See ANGELECA.

GOUTY land, in agriculture, a term used by the farmers to denote a hollow luxuriant black earth with little springs, that have no free outlet, and therefore swell and elevate the surface in many places.

GOWN, *veil*, a long upper garment, worn by lawyers, divines, and other graduates, who are hence called *gentlemen of the gown*, or *gown-men*.

The *gown* is an ample sort of garment, worn over the ordinary cloaths, hanging down to the feet. It is fashioned differently for ecclesiastics, and for laymen.

At Rome, they give the name *vestis gown*, *vestis virilis*, to a plain kind of gown, which their youth assumed when arrived at puberty. This they particularly denominated, *prætexta*.

In some universities, physicians wear the scarlet gown. In the Sarcophagus the doctors are always in gown and cap. Bealies, &c. wear gown of two colours.

Among the French officers, &c. they distinguish those of the *short gown*, or robe; which are such as have not been regularly examined. They have also borders of the *short gown*, who are such as are obliged to practise in an inferior way to surgeons, or those of the long robe.

GOWN is also taken, in the general, for the civil magistrature, or the profession opposite to that of arms.

In this sense it was that Cicero said, *Clodius arma togæ*.

GRABATARI, *GRABATARI*, in Church Antiquity, such persons as deferred the receiving of baptism till the hour of death; or who did not receive it till they were dangerously ill, and out of hopes of life: from an opinion, that baptism absolutely washed away all former sins.

The word is formed of *grabatum*, bed, and that from

the Greek *γρῦναι*, a hanging bed, of *grapes*, *grapes*, such as was the bed of slaves, poor people, Cylic philosophers, &c. who are enemies of luxury and ease.

GRACULUS, in Ornithology. See JACK-JAW.

GRACE, *GRATIA*, in Theology, any gift which God confers on men, of his own free liberality, and without their having deserved it at his hands; whether such gift regard the present or future life.

Grace is usually divided into *natural* and *supernatural*.

GRACE, *natural*, includes the gift of being, of life, of such and such faculties, of preservation, &c. St. Jerome, Epist. 139. allows it a *grace* of God, that man was created. *Gratia Dei est, quod homo creatus sit*. So also it is by the *grace* of God, that angels and human souls are immortal; that man has free-will, &c.

GRACE, *supernatural*, is a gift from above, conferred on intelligent beings, in order to their salvation.

There only, are called *grace* in the rigour of theology; and it is for the conveyance, improvement, and strengthening of them, that the sacraments are conferred, the ministry of the word instituted, &c.

Divine distinguish *supernatural grace* into *habitual* and *actual*, *justifying* and *sanctifying*.

GRACE, *habitual*, is that which resides stably in us, is fixed in the soul, and remains all some previous willful sin expunged. This is also called *justifying grace*, as it makes us appear righteous and innocent before God; and *sanctifying grace*, as it makes us holy and devoted to God.

GRACE, *actual*, is that which God gives us for the special performance of some particular good thing; as to convert us, enable us to resist a temptation, &c.

This is divided subdivided into three kinds; *preventing*, *concurrent*, and *subsequent grace*.

It is an article of faith, 1. That *actual grace* is necessary for the beginning, carrying on, and finishing every good work. 2. That the will is able to resist the *grace*, and reject it.

And hence *grace* becomes further divided into *efficient* and *inherent*. It is *efficient*, or efficient, when it produces the effect; and *inherent* when it does not, though it might have produced it.

Some of the more rigid Calvinists, &c. admit a necessitating *grace*.

We also for the *law of grace*, the amount of *grace*, in opposition to the *Mosaic law*, &c. See REVELATION, &c.

GRACE, *act of*, properly denotes an act of amnesty, or oblivion; for the pardon of all offenders who are qualified, or come within the conditions of it.

The term is also sometimes extended to an act made for relief of insolvent debtors in the several prisons; by setting those who are qualified, at liberty from their debts, and confinement.

GRACE, *deeds, or rewards*. See DAYS OF GRACE.

GRACE, in Law, is sometimes used for a faculty, licence or dispensation; but this term is to be only in a case, where the matter precedeth, as it were, *ex gratia*, of *grace* and favour; and not where the licence or dispensation is granted of course or of necessity.

GRACE is also a term in the formula of all patents, &c. which begin, *Georges by the grace of God, king of Great Britain*, &c. The British bishops frequently begin their mandates in the like manner: such as, *by the grace of God, and the holy see, bishop of*, &c.

The English *archbishops* begin, by *divine grace*, or *divine providence*.

All sovereigns use the phrase *grace of God*; as emperors, kings, princes, &c. Anciently dukes, counts, and even knights, styled to the time this. In the new collection of *Stat. Martini*, we meet with a mere *seigneur*, or lord, qualified by the *grace of God*, *seigneur de Comborn*. Louis XI. styled the duke of Brittany to style himself by the *grace of God*.

GRACE is also a title of dignity, attributed to princes of inferior rank, and who are not qualified for that of highness.

In former times the kings of England were addressed under this title of *grace*, as they now are under that of majesty. See KING.

Our English dukes and archbishops are still addressed under the title of *grace*. But that title is most frequent in Upper Germany, and particularly Austria where it is borne by the bishops, as being inferior to that of excellence.

GRACE is also applied to persons, and various kinds of performances, to denote a quality, or rather the result of a combination of qualities, which attracts peculiar notice, and affords peculiar pleasure.

GRACE is also used for a short prayer offered to fore and after meat. This practice is very ancient, and has very

generally obtained both in the heathen and Christian world; and hence *grace-up* is used by some of our poets for the cup or health drunk after *grace*.

GRACE, *verb off*, in Botany. See RUI.

GRACES, *GRATIAE*, in the *Classical*, are the same with what we otherwise call *prayers*.

GRACES, *explicative*, *gratia explicativa*. See EXPECTATIVE.

GRACES, *GRATIAE*, *Charities*, in the *Heathen Theology*, were fabulous deities, three in number, who attended on Venus.

Their names are Aglæa, Thalia, and Euphrosyne; the first, smiling, and gay; and they were in honour by some to be the daughters of Jupiter, and Eurydice the daughter of Oceanus; and by others to be the daughters of Bacchus and Venus. Vossius de Idol. lib. viii. cap. 15.

Some will have the *Graces* to have been four, and make them the same with the *Horæ*, *Hours*, or rather with the four seasons of the year.

A marble in the king of Prussia's cabinet represents the three *Graces* in the usual manner, with a fourth, seated, and covered with a large veil, with the words underneath, *AD SOCRATES IIII*. Yet Mous. Beger will by no means allow the *Graces* to have been four; the company there present, he understands to be the three *Graces*, and Venus, who was their sister, as being daughter of Jupiter and Dione.

They are always supposed to have held of each other's hands, and never parted. They were painted naked to show that the *Graces* borrow nothing from art, and that they have no other beauties than what are natural.

Yet, in the first ages, they were not represented naked, as appears from Pausanias, lib. vi. and lib. ix. who describes their temple at Sicyon. They were of wood, all but their head, feet, and hands, which were white marble. Their robe, or gown, was gilt; one of them held in her hand a rose, another a dye, and the third a spring of myrtle.

GRACILIS, in Anatomy, a muscle of the leg, thus called from its slender shape. See Tab. Anat. (Anat. fig. i. n. 54. fig. 2. n. 37. fig. 6. n. 37).

It arises partly tendinous, and partly fleshy, from the espulis internally, between the first and second heads of the triceps; and in its descent on the inside of the thigh, grows narrow, and becomes tendinous, a little below the Sartorius, and is thus inserted into the tibia. It assists in bringing the thigh and leg forwards.

GRACILIS, *relaxus*, in Anatomy, a name given by Riolan to one of the muscles of the leg, called by Winflow the *relaxus curvis interior*, and by Cooper the *relaxus femoris*. Albinus calls it the *relaxus cruris*.

GRACULA, in the Linnaean system of Ornithology, a distinct genus of birds, of the order of the *Psittaci*. The distinguishing character of which is, that the beak is of a convex shape, almost naked at the base; the tongue is entire, a little acute and fleshy; and the feet are ambulatory. Of this genus, Linnaeus reckons eight species, none of which are found in Europe.

GRACULUS, *palmipes*, in Ornithology, a name given by some to a bird, called in England the *hedge*, and by Mr. Ray the *corvus aquilinus minor*, or lesser corvid, being regularly a species of that bird.

GRADATION, the act of ascending step by step, to any pitch or eminence; from the Latin *gradus*, degree, step. **GRADATION**, in Architecture, signifies an artful disposition of parts, rising, as it were, by steps or degrees, after the manner of an amphitheatre; so that those placed before do no disservice, but rather service, to those behind.

The painters also use the word *gradation* for an insensible change of colour, by the diminution of the tints and metals.

GRADATION, in Chemistry, is a kind of process belonging to metals. It consists in gradually raising, or exalting them to a higher degree of purity and goodness, so as to increase their weight, colour, confidence, &c.

GRADATION, in Logic, is an argumentation, consisting of four or more propositions, so disposed as that the attribute of the first is the subject of the second; and the attribute of the second is the subject of the third; and so on, till the last attribute come to be predicated of the subject of the first proposition. As in Porphyry's *ladder*, which is an animal; an animal is a living thing; a living thing is a body; a body is a substance; therefore, an animal is a substance.

An argument of this kind is liable to many objections; both from the ambiguity of words and things; as, *gr. Peter is a man; man is an animal; animal is a genus; genus is a universal; therefore Peter is an universal*.

GRADATION, in Rhetoric, is when a series of considerations or proofs is brought, rising by degrees, and improving each on the other. See CLIMAX.

Such is that in Cicero to Herennius: *Africans indigna veritatem, virtus gloriam, gloria amulic comparavit.*

GRADO, in the Italian Music, signifies degree; thus *di grado* is used to denote *compositi arpeti*, which is when the notes rise or fall from space to line, or from line to space, without making any leap of a third, fourth, or other interval. See **SALTO**.

Di grado ascendente intimates, that all the notes rise by *compositi arpeti*; as *ut, re, mi, fa, sol*.

Di grado descendente, is when all the notes descend or fall by *compositi arpeti*; as *sol, fa, mi, re, ut*. See **DEGREE** and **CONJOINT**.

GRADUAL, **GRADUALE**, was anciently a church-book, containing divers prayers, recitation, or sung, after the epistle.

In some of our ancient writers it is read *gradus*, *gradual*, *grails*, &c.

After reading the epistle, the chanter ascended the ambo with his *gradual*, and rehearsed the prayer, &c. therein; being answered by the choir: whence the name *gradual*, on account of the steps or degrees of the ambo.

The *gradual*, or *grail*, which the provincial constitutions of archbishop Winchelsey, made at Norton, A.D. 1305, required to be in every church, was a book containing all that was to be sung by the choir at high mass; the tracts, lectiones, litanies, the creed, offertory, trisagium, and also the office for sprinkling the holy water. *Gradale, per ditionem, a gradatione in tali libro constituta.*

It is sometimes taken for a mass-book, or part of it, instituted by pope Celestine, anno 430. See list. 37 Hen. VI. c. 12.

In the Romish church, *gradual* is an appellation still given to a verse which they sing after the epistle, and which was anciently rehearsed on the steps of the altar: though Ugolin gives us another account, and says it took its denomination *gradual*, because sung in the *gradual* ascent from note to note. Mayer speaks differently still, and will have it to have taken its name because sung while the deacon went up the stairs to the pulpit, to sing the Gospel.

GRADUAL, **GRADUALIS**, is also applied to the fifteen Psalms, sung among the Hebrews, on the fifteen steps of the temple. Others are rather of opinion, that they were thus denominated because the fingers raised their voice by degrees, from the first to the last.

Cardinal Bona, in his treatise of Divine Psalmody, says, the fifteen *gradual* Psalms are intended to represent to the mind, that we only arrive at the perfection of goodness, or holiness, by degrees. He goes on to lay down the fifteen degrees of virtue, corresponding to the fifteen Psalms; five of them are for beginners; five for proficient; and the rest for the perfect.

GRADUATE, a person who has the degrees of any faculty. A *graduate* in physic, in divinity, &c. See **DEGREE**, **DOCTOR**, &c.

In France, one third of the benefices of the kingdom are appropriated to *graduates*; viz. all that become vacant in the months of January, July, April, and October.

This privilege of *graduates* is no older than the fifteenth century: it being observed, that men of learning were much neglected by the collators, and patrons of churches, complaint therefore was made to the council of Bulli, where this decree was made; which was afterwards confirmed by the Pragmatic Sanction, and again by the Concordat.

GRADUATION is used, in *Mathematic*, for the act of *graduating*, or dividing any thing into degrees.

For an account of the various methods of *graduating* mathematical and astronomical instruments by straight and circular diagonals, and by concentric arcs, &c. see **PLATE SCALY**, **NORMA**, and **VERNIER**.

For an account of Mr. Bird's improved method of dividing astronomical instruments, see **MURRAY** *orbis*.

We shall here only observe, that Mr. Ramsden, an ingenious mathematical instrument maker of London, has lately published, by order of the commissioners of longitude, an explanation and description of an engine, contrived by him for dividing mathematical instruments, recommended by proper drawings, in consideration of which the said commissioners have granted to him the sum of 615*l*. This engine consists of a large wheel of bell-metal, supported on a mahogany stand, with three legs; on each leg of the stand is placed a conical friction pulley, whereon the dividing-wheel rests; and to prevent the wheel from sliding on the friction pulleys, the bell-metal centre under it turns in a socket on the top of the stand. The circumference of the wheel is ratched or cut into two thousand one hundred and sixty teeth, in which an endless screw acts; so that six revolutions of the screw will move the wheel through one degree. A circle of brass is fixed on the screw-rod, whose circumference is

divided into sixty parts, and, therefore, each division will answer to a motion of the wheel of ten seconds, and six of them will be equal to a minute, &c. Several different arbors of tempered steel are truly ground into the socket in the centre of the wheel. The upper parts of the arbors that stand above the plane are turned of various sizes, to suit the centres of different pieces of work to be divided. When any instrument is to be divided, the centre of it is very exactly fixed on one of these arbors, and the instrument is fixed down to the plane of the dividing-wheel by means of screws, which fit into holes made in the radii of the wheel for that purpose. The instrument being thus fitted on the plane of the wheel, the frame which carries the dividing-point or tracer is made to slide on the frame which carries the endless screw to any distance from the centre of the wheel, as the radius of the instrument to be divided may require, and may be there fastened by tightening two clamps; and the dividing-point being connected with the clamps by the double jointed frames, admits a free and easy motion towards, or from the centre, for cutting the divisions, without any lateral shake. In this way an instrument, fitted on the dividing-wheel, may be moved to any angle by the screw and divided circle on its arbor, and this angle may be marked on the limb of the instrument with the greatest exactness by the dividing-point or tracer, which can only move in a direct line tending to the centre, and is altogether freed from the inconveniences that attend cutting, by means of a straight edge. This method of drawing lines will also prevent any error that might arise from an expansion or contraction of the metal during the time of dividing.

The screw frame is fixed on the top of a conical pillar, which turns freely round its axis, and also moves freely towards or from the centre of the wheel, so that the screw-frame may be entirely guided by the frame which connects it with the centre. By this means any eccentricity of the wheel and the arbor would not produce any error in dividing; and, by a particular contrivance, the screw when pressed against the tooth of the wheel always moves parallel to itself, so that a line joining the centre of the arbor and the tracer continued, will always make equal angles with the screw. For the farther construction and use of this engine, see Description of an Engine for dividing Mathematical Instruments, by Mr. J. Ramsden, anno 1777.

GRADUS geminus. See **GENOMIA**.

GRÆA, **YANA**, a name used by the old Greek writers for the wrinkled pellicle which arises upon milk in the boiling.

It was also used in a figurative sense for the wrinkles in the skin of old people.

GRÆCOM. See **GRÆCOM**.

GRÆTER, from the French *griffer*, i. e. *scrub*, a miter, or scriber. It is used in the stat. 5 Hen. VIII. cap. 11.

GRÆTIO, or **GRÆVIO**, in our Old Writers, denotes a landscape or earl. *Nec principis nisi grætio, hanc hantatem nature videtur.*

GRÆTIUM, in our Old Writers, is used for a writing-book, register, or chartulary of deeds and evidences.

GRÆFT, or **GRÆFT**, in *Agriculture* and *Gardening*, a little shoot, clod, bud, or eye of a tree, inserted into another tree to make it yield fruit of the same nature and kind as those of the tree whence the *græft* is taken.

The word is formed of the French *græft*, which signifies the same thing; and *græft*, in this sense, is supposed to have been derived from the resemblance the shoot bears to the point of a penknife, which was anciently called *græft*. Dr. Cange goes farther, and derives the ancient *græft* from *græftionis*. Menage, from *græftum*, a Latin word, signifying a little stile, or iron book; one end whereof was pointed, and served to write on waxen tablets; and the other flat, serving to efface, or rub out what was written.

A *græft* is a little portion of a tree, inclosed in a cleft or incision made in another, in order to correct, qualify, or improve the state of its fruit; or even to make it bear a different sort of fruit.

In the choice of *græfts*, the following directions should be observed: that they are shoots of the former year; that they must be taken from healthy fruitful trees, neither sickly, nor young and luxuriant; that they be taken from the lateral or horizontal branches, and cut off from the trees before their buds begin to swell, which is generally three weeks or a month before the season for grafting; and, therefore, they should be laid in the ground with the cut downwards, burying them half their length, and covering

covering their tops with dry litter, to prevent their drying. If a small joint of the former year's wood be cut off with the graft, it will help to preserve it, and when they are grafted, this may be cut off. When the grafts are carried to a considerable distance, their cut ends should be put into a lump of clay, and wrapped up in moss, and thus they will be preserved fresh for a month or longer; but these should be cut off earlier from the trees than those which are to be grafted near the place where the trees are growing. *See* FAULT-GRASS.

GRAFTING, or GRAFTING, or INGRAFTING, in Agriculture and Gardening. *See* ENGRAFTING.

GRAFTING WOOD. *See* WOOD, &c.

GRAIN, GRAMINUM, primarily denotes a fruit, or seed, growing in a spike, or ear.

In this sense, grain comprehends all sorts of corn, as wheat, rye, barley, oats, &c.

GRAIN, fructus of. There are three particulars observable in every grain, whether it be wheat, barley, oat, or whatever else of that kind. These are, 1. The outer coat or pellicle, which contains all the mill. This in the same species of grain is found to be very different in thickness in different ears, and as it has grown in different soils. 2. The germ or bud; this is always hid within the feed or grain, and is the plant in miniature that is to arise from it. And, 3. The meal, or that farinaceous matter which is included in the skin, and which surrounds the germ, and serves to give it nourishment when first put into the earth, before it is capable of drawing it from the earth itself. Dr. Grew, in his Anatomy of Plants, has treated of this at large. *See* VEGETATION, &c.

The whole structure of the plant which produces these seeds is equally admirable. The chaffy husk is admirably adapted to shield and defend the seed as long as that is necessary, and then to let it fall; and the stalk formed hollow and round is usefully at once light and strong, capable of sustaining the ear, without absorbing too much of the juices destined to its nourishment; and the beards of many kinds are a defence against the birds, that would otherwise destroy the seed before its ripening. The covering of the seed is formed of two membranes, which meeting in a line on one part of the seed, form together that furrow we see on it. This is the place at which the seed is to burst open on being imbibed. Had not nature provided this means of the germ's coming out, the toughness necessary to the coat of the seed, as a defence from injuries, would have sufficed the farinaceous matter and the germ to rot together, within it, before it would have given them time to come out, and for the germ to grow.

Not is this the only use of this place of opening. The great Creator of all things has provided these seeds, not only for a supply of the same species of plant, but for our food, and for that of birds, &c. We have art enough to erect machines for the reducing the farina to powder, and the freeing it from its covering membrane; but the birds eat it as it is, and it would pass through them whole, and without doing them any good, were it not that the juices of the stomach swelling it up, it bursts open at this furrow, and all the nutritive matter pours itself out. *See* JANDER, Traité. Phys. p. 62.

This farinaceous matter is composed of an infinite number of white and transparent bodies, of a globular figure, these every way surround and inclose the young plant, and by their figure being easily put in motion, as soon as the heat and humidity of the earth act upon them, they, by degrees, force themselves into the vessels of the plant, and give it increase from time to time till they are received into it; and they then have so far given it strength, that it is in a condition to feed on the juices in the earth. The same process of nature is observable in the case when grain of corn grow out of time, on being thrown too carelessly together in a moist place.

When the corn is ground into powder, these farinaceous globules make what we call the flour. The germs are always less white, and less transparent than they, but they are of great use; since it is principally to them that we owe the agreeable flavour of bread, and almost wholly to them, that the fermentation of dough is owing, their little parts being, of all others of the grain, the most easily put in motion. And it is also to these, that the rotting of wheat, preserved in damp granaries, is to be attributed, their natural tendency being to motion and to corruption, if that motion be given without the necessary accident. That the observation of the fermentation of dough, and the lightness of bread, being owing to these germs, may not seem advanced at random, it may be proper to confirm it, by the observations of the people employed in making bread for the army. These people always find, that fine flour, if well dried, and put up in dry barrels, will keep good a long time; but that

after it has been thus kept long, though it will make light, and serve for many other necessary uses, it will never make the fine light bread eaten at tables; and they attribute to the life of the hour being spent; that is, to these germs being destroyed, as to their vegetative power, by having been a long time broken to pieces. *See* COAR.

For the laws relating to the importation and exportation of several sorts of grain, or wheat, barley, oats, &c. *See* WHEAT, HORDEUM, OATS, &c.

GRAIN is also applied to the fruits or seeds of diverse plants, as a grain of millet, of pepper, &c.

GRAIN is also extended to a minute body, or parcel of a body pulverized. In which sense we say, a grain of salt, a grain of sal, a grain of gunpowder, &c.

GRAIN denotes also a small weight, used in estimating very subtilances.

The grain is the smallest of all weights known in England. It is taken from the weight of a grain of wheat, gathered out of the middle of the ear, and well dried. By that, 12 Hen. VII. cap. 7, every sterling or penny-weight was to weigh thirty-two such grains; but now twenty-four grains make a penny-weight, and twenty penny-weights an ounce. *See* POUND and WEIGHT.

The grain is Troy-weight, and used in the weighing of gold, silver, jewels, bread, and liquors.

Among the ancients, the grain was the fourth part of the siliqua, or twelfth of the obolus, and the twenty-second of the drachm. It coincided with the.

Pernicius, lib. 16. cap. 6. Method. Medec. d. affirms it as a thing known and certain, that the grain is of the same weight every where; but he is mistaken. Mr. Graves, in his treatise of the Denarius, in his Miscell. Notes, vol. 1. p. 276, has shown, that 179 Dutch grains, which Stollius had found to be the weight of a Philip of gold, only amount to 134 English grains. Arch. that Mont. Perreault has computed the French grain to be less than the English, and yet bigger than the Dutch; to the English, it is as 148 to 134½; and to that of Holland, as 148 to 179. *See* WEIGHT.

The grain used by the apothecaries is the same with that of the goldsmiths; though they make a difference in the weights raised the system. Thus, to grains, with them, make a scruple, 34 3 scruples, a drachm, 34 3 drachms, an ounce, 5, &c.

The carat used in estimating the fineness of gold as well as in weighing diamonds and precious stones, is also divided into four grains; and the carat is about the one hundred and fiftieth part of an ounce Troy, according to Mr. Jeffreys, in his treatise on Diamonds and Pearls.

Hence, the Jewellers grain is to the Troy grain, inversely, as 500 is to 480, that is directly as 4 to 5.

GRAIN is also used for the figure or representation of grains on bones, fluff, feathers, &c. Thus, we say, morocco has a bolder and richer, that is, a larger grain, than shagreen.

In some marbles, the grain is very fine; in others coarser. Steel is known by its grain, which is much finer than that of iron.

GRAIN of iron. Even iron has its grain as well as wood, and that not the same in all iron, though all iron is very evidently the same species of body. The common cast iron has a grain very different from that which has been hammered, or wrought, the granules which compose the mass being in this last state forced as it were into combinations with one another, by the repeated blows of the hammer: the tempering of iron into steel also alters its grain, partly by means of the salts and sulphurs, which are by that operation introduced into it, and partly by the knocking the effect of the fiery particles received into it at a certain time.

But beside these differences, the common wrought iron has in its several pieces, or sometimes in the several parts of the same piece, different grains. First a laminated one, secondly a granulated one, and thirdly a fibrous or stringy one. These, however, are not so different, in reality, as they appear to be, for the laminæ, as they become smaller, become granules; and arrangements of these granules, in long lines, make the fibres of the stringy kind. The artificers, however, know by their marks of the grain what iron is fittest for tempering into steel; and they find the laminated pieces to be the most elastic, and the granulated ones the best. *Mem. Acad. Sci. Paris, 1722. See* IRON and STEEL.

Much has been said about the difference of iron, of lead-ore, but these are three, just as lead-ore is, owing only to the size and arrangement of the iron-based particles as in the iron. The broad grained lead-ore being analogous to the laminated kind of iron, the steel grained being equally analogous to the granulated iron, and what is called the ammoniated lead-ore, being in the same manner analogous to the fibrous grained iron,

iron, and all in the same manner arising out of one another.

GRAINS, in *Clemistry*, or the feeds of vegetables, are distinguished into emulsive, which yield a considerable quantity of mucilage and oil, which may be separately extracted from them; such are almonds, and the feeds of almost all fruits; and farinaceous, which are entirely composed of a dry substance, easily reducible into a fine powder, called meal. Of this kind are the grains of all graminaceous and leguminous plants.

GRAIN, cochinal. See COCHINEAL.

GRAIN, farle. See SCARLET.

GRAIN, sly, Myogram, in *Botany*. See GOLD of Pleasure.

GRAIN-Tin. See STREAMING.

GRAINS of Paradise. See CARDAMOMUM and AMOMUM.

GRAINED medals. See MEDAL.

Grass GRAINED fluff. See CROSS grained.

GRAINING, in *Etymology*, the name of a fish found in the Mersey, near Warrington; it resembles the dace, but is more slender, and has a flatter back.

GRAINING board is a board used by the curriers, to give the grain to their leather.

It is made with teeth, or notches, running quite across; into which the soft, moistened, suppled leather being pressed, its surface readily takes the impression. See CURVING.

GRALLÆ, in *Ornithology*, is an order of birds analogous to the *serae* in the class of MAMMALIA, in the Linnean system; the characters of which are, that the beak is fulcriform and somewhat obtuse; the tongue is entire and fleshy, and the thighs above the knees are bare. This order comprehends eighteen genera, among which are the PHOEBICOPTERUS, the ARDEA, SCOLOPAX, TINGA, &c.

GRAMIN, in *Botany*. See GRASS.

GRAMIN MISTUM, *Misa longissima*. See FESTUCA.

GRAMINEA, in *Antiquity*, is applied to a crown formed of grass, *gramen*, bestowed by the Romans on certain of their generals, in consideration of their having saved or rescued an army.

The *grassy crown*, *corona graminea*, was but rarely conferred, and for some single exploits; when, through the courage or desertion of a general, an army reduced to the last extremities had been saved, or delivered, and the enemy put to flight.

GRAMINEOUS herbs, among *Botanists*, are such as have a long, narrow leaf, with no footstalk.

GRAMINIFOLIA, in *Botany*, a name given by Dillenius to a genus of plants, called by Micheli and Linnaeus ZANNIHELLIA.

GRAMMAR, the art of speaking properly; that is, of expressing one's thoughts, by signs mutually agreed on for that purpose.

The signs here signified most convenient, are articulate sounds; but as these are transient, others have been invented more permanent, viz. *grammata*, *symplicata*, letters, whence the name *grammar*.

So that *grammar* is the art of rightly expressing our thoughts by words; and it is either *universal* or *particular*. *Universal grammar* explains the principles, which are common to all languages. See PHILOSOPHICAL GRAMMAR. And the *grammar* of any particular language, applies those common principles to that particular language, according to the established usage and custom of it.

Grammar is more extensively defined, after Mr. Johnson, the art of expressing the relations of things in construction, with due quantity in speaking, and orthography in writing, according to the custom of those whose LANGUAGE we learn.

Grammar is divided by some authors into four parts, ETYMOLOGY, ORTHOGRAPHY, PROSODY, and SYNTAX.

Others choose to divide *grammar* somewhat more obviously into the doctrine of *letters*, or *sounds*, which coincides with orthography and orthoëpy; that of *syllables*, their accent, time, &c. which falls in with prosody; that of *words*, their kinds, derivations, changes, analogy, &c. which amounts to etymology; and that of *sentences*, which considers the placing, or joining of words together, called *syntax*.

The chief business of *grammar* is, to decline, conjugate, construct, and spell nouns, verbs, and other parts of speech. It teaches the propriety, and natural force, of each part of discourse; and the reason of all expressions used therein.

So that the *grammar* of any particular language enables us to express ourselves with propriety in that language, and to judge of every phrase and form of construction, whether it be right or not. Besides, there is a secondary use to which it may be applied; viz. the facilitating of the acquisition of other languages, whether ancient or modern.

VOL. II. No 157.

Some have called *grammar* the door, or gate, of the arts and sciences; because none of these are attainable but by means thereof. *Grammar*, according to Quintilian, is that to eloquence, which the foundation is to the building; they who despise it, as only dealing in low, trivial things, are exceedingly mistaken; it had really more solidity than these.

Diogenes Laertius relates, after one Hermippus, that Epicurus was the first who gave the rules of *grammar* for the Greek tongue; but that Plato was the first who had taken the thing into consideration, and that he had even made some discoveries on that subject.

At Rome, Crates, surnamed Malloë, contemporary with Aristarchus, gave the first lectures on *grammar* to the Romans, during the time of his being ambassador for king Attalus, to the commonwealth, between the second and third Punic wars, soon after Cæsar's death. Before him, it was not known at Rome what *grammar* meant. Polydore Virgil invents. *Ver. lib. ii. cap. 7.*

Grammar is the same in all languages, as to its general principles, and notions, which it borrows from philosophy to explain the order and manner wherein we express our ideas by words; but, as each language has its particular turns, its several characters, and genius, different from the genius and character of other languages; hence arise so many *grammars* to languages. An example will suffice to show that we say in English, *draw a straight line*, *trace a line*; in French, they say, *tracer une ligne droite*, *tracer une ligne*; in Italian, *tracciare una linea*, *tracciare una linea*; and in Latin there is a liberty to say either the one way or the other, *tracere lineam*, or *lineam traccare*, &c. And if there be a language which in the phrase above mentioned follows the same analogy as the English, it differs from it so a hundred other occasions.

Hence Dr. Wallis very justly finds fault with our English grammarians, where he says, that all of them, forcing our English tongue too much to the Latin method, have delivered many useless things concerning cases, genders, and declensions, of nouns; tenses, moods, and conjugations, of verbs; as also the government of nouns and verbs; which our language has nothing to do with.

GRAMMAR is also used for a book containing the rules of *grammar*, which obtain in any language. See LANGUAGE.

The ancient *grammars* are; for the Hebrew that of rabbi Juda Ching, which is commonly held the first Hebrew *grammar* that appeared; though it is certain, rabbi Sandias Haggason, who lived before rabbi Juda, composed two works in the same kind: one, expressly of *grammar*; and the other of the elegancies of the Hebrew tongue.

For the Greek, the eldest *grammar* is that of Gaza: the *Latin* ones are the works of Martinus Capella, Priscian, and Afonius Perellanus.

The modern *grammars* are: 1. For the Hebrew, that of Pagninus, the edition of Hen. Stephens, or le Preux; at Geneva, in 1593; that of Petrus Martinus at Rochel 1592, that of Buxtorf; that of Ludovicus Deuy, in three languages; that of Sixtus Amama, which is a collection from Martinus and Buxtorf; that of Bel Jarmino, with the notes of Moit; those of F. Schultze, of W. Schickard, and of Vici. Bythner, to the latter of which is annexed a brief account of the Chaldee, are useful for beginners. 2. For the Chaldee, the best are those of Martinus Buxtorf, and Lud. Deuy, in three languages. 3. For the Syriac, those of Amira, Myricus, Waserus, and Beveridge; with the Chaldee and Syriac ones of Buxtorf, of Lud. Deuy in three languages, and that of Lemblen. 4. For the Copric, the Prodromus Copricus, and Lingua Aegyptiaca Restitutio of Kircher. 5. For the Arabic, that of Erpenius, and that of Golius, which is only Erpenius's a little augmented. 6. For the Ethiopic, that of J. Ludolphus. 7. For the Persian, that of Lud. Deuy. 8. For the Armenian, those of Schroeder, and Galamus. 9. For the Greek, those of Mart. Rulandus, Sybburgus, F. Moquet, Vollius, Buxtorf, and Port Royal. 10. For the Latin, those of Desputer, the Miscellanea Sandiana, those of Yousius, and Opera that of Port Royal, which is only a collection from the rest; and that of Lower, the most exact of all. 11. For the Italian, those of Berger, Landreth, Port Royal, and Venetico. 12. For the Spanish, those of Salazar, Port Royal, the abbot de Valency, &c. 13. For the Portuguese, that of Perena. 14. For the French, those of the abbe Regnier, and F. Butler. 15. For the High Dutch, those of Clarius, Heerburgensis, Schottelius, Boedicher, and Stelmach. 16. For the English, those of Wallis, Brightland, Greenwood, Lowth, and Priestley.

GRAMMAR is also used in the same sense with *elements*; as *geographical grammar*.

Philosophical GRAMMAR, is that which, without regarding the several turns of particular languages, only respects those

those principles that are essential to them all. One of this kind was proposed by lord Bacon; not upon the analogy of words, but such as should diligently examine the analogy or relation between words and things. He disapproves too curious an enquiry about the original imposition and etymology of names. This he thinks an elegant, and as it were, a waxes subject, that may be handsomely wrought and twined, but is attended with little truth and advantage. But, says he, it would be a noble kind of *grammar*, if any one well versed in languages, both the learned and the vulgar, should treat of their various properties, shewing wherein each of them excel and fall short: for these languages might be enriched by mutual commerce, and one beautiful image of speech, or one grand mode of language, for justly expressing the sense of mankind, be formed like the Venus of Apelles, from the excellences of several. And thus at the same time we should have some considerable marks of the genius and manners of people and nations, from their respective languages. See *Isaac's Doctrine of Delivery*, sect. 7. and *De Augm. Scient.* vi. r.

The object of philosophical or universal *grammar* is speech or language, as divided into its constituent parts, as a statue may be divided into its several limbs, or else, as resolved into its matter and form, as the same statue may be resolved into its marble and figure: and thus it is distinguished from the art of *logic*, which considers speech as combined or compounded; so that, by this synthesis, simple terms are combined to produce a truth, and two truths are combined to produce a third, &c. In this kind of *grammar*, the design is to point out the several powers and modes of expression which *languages* are capable of, to trace their connections with, or relation to the ideas they represent; and to shew the actual variety of the external expressions of the same mental conceptions which different languages exhibit. By this comparison we shall be enabled to judge which is the most adequate and convenient method of expression, what is defective and what is redundant in the structure of any particular language, and direct to the most proper method of supplying the defect, or lessening the inconvenience arising from the superfluity. See *LANGUAGE*. See an extensive and well known work of this kind by the ingenious and learned Mr. Harris, called the *Hermes*, or a Philosophical Enquiry concerning Universal Grammar, 2d edit. 1765.

GRAMMAR, characters in. See *CHARACTER*.

GRAMMARIAN, GRAMMATICUS, a person well versed in grammar; or who teaches grammar.

The denomination *grammatician* is, like that of critic, now frequently used as a term of reproach; a mere *grammarius*; a dry, plodding *grammarian*, &c. The *grammatician* is conceived as a person wholly attentive to the minutiae of language; industriously employed about words, and phrases; and incapable of perceiving the beauties, the delicacy, fineness, extent, &c. of a sentiment.

Scaliger, however, considered *grammaticians* in another light. *Ultimus illius, say he, bonus grammaticus: i. iustitiam ei, qui tenet auctoritate probe vult intelligere, ut grammaticum.*

The title *grammatician*, it is certain, was anciently a title of honour; being given not only to such as applied themselves to grammar, or excelled in philology; but to all who were reputed learned in any art or faculty whatsoever, as it is shewn by Ger. Vossius, in his book of *grammaticians*.

The word was properly a title of literature and erudition, and was frequently given to persons who excelled in all, or many arts, called also *polyhistor*.

This, Philoponus, a famous philosopher in Justinian's time, remarkable for the extent and variety of his knowledge, was furnished *Grammaticus*; as appears from Photius's Bibliotheca.

So Saxo, the Danish Historian, in the thirteenth century, got the appellation *Grammaticus*; and as late as the year 1580, Thomas d'Aversa, a celebrated Neapolitan lawyer, was furnished the *Grammatician*.

The title *grammatician* was anciently bestowed on those we now call *critics*, men of learning, erudition, letters, &c. and particularly such as wrote well, and politely, in every kind.

It is in this sense that Suetonius intitles his book which he wrote on the best Latin authors, *De illis celebratis Grammaticis*; and that Cornelius Nepos calls the commentators on the orators and poets, *grammaticians*; and lastly, it is in this sense the appellation is attributed by the ancients to Apion, Philoponus, and Sossius.

The most celebrated *grammaticians* of the second century were Ajer, Pollio, Eutychius, Proculus, Albanius, Julius Pollux, Macrobius, and Aulus Gellius; the works of these last authors are an assemblage of abundance of

very different things, and subjects, relating to the criticism of the ancient writers, and the polite literature.

If the name have lost its ancient honour, it is through the fault of those who have assumed it; by their treating of *grammar* in a low, pedantic, dogmatic manner; reducing it to words and syllables; and dwelling altogether on trifling puerile remarks, and censures: whereas its ancient office was, to make an accurate and thorough examiner of an author; to enter into all his views; to point out the beauties, and the defects thereof; to distinguish the true beauties from the false; and the genuine productions of an author, from the supposititious; that is, a *grammarian* was then, what we call a critic now.

Those who only taught to read, understand, and explain authors, were called *grammatists*, *grammatistae*; in contradistinction from *grammatici*; though, in course of time, the *grammatistae* have risen in the place of *grammatici*; who are now preferred to that of critic.

GRAMMATICAL, something relating to GRAMMAR.

We say, *grammatical* construction; *grammatical* signification, &c. *Idioms*, as *Anglicisms*, *Latinitas*, *Gallicisms*, &c. deviate from *grammatical* strictness. Such a phrase is not *grammatically* just; it is an idiom.

GRAMMATICAL criticism. See *CRITICISM*.

GRAMMELOUC, in *Natural History* the name of an East Indian shrub, very common in the woods and forests.

It grows to five or six feet high; its leaves are very long and narrow, and terminate in a point; they are of a lively green; the fruit is carried by a long, a triangular shape, of the size of a hazel-nut, has something longer; on opening this there appear three cells, in each of which is contained one fruit, resembling the seed of the palma Christi, but covered with a transparent pellicle, and a black one under that: the inside of the fruit is white, and is of a sharp and pungent taste. It is a very violent medicine, operating both by stool and vomit, and that often so as to endanger the life of the person who has taken it. They allow its operation by eating BETEL. Mem. Acad. Par. 1699.

GRAMPUS, in *Ichthyology*, the *dolphin* *grampus* of Linnaeus, an English name given to one of the cetaceous fishes, properly of the genus of the *DELPHINUS*, or *dolphin*, according to the new Artedius system, and distinguished from the others of that genus by the name of the *dolphin* with the snout bending upwards, and with broad serrated teeth. This is the *orca* of almost all the ancient as well as modern writers, and it called the *seper* and *north-seper* by the people of Scotland. Sir Robert Sibbald gives it the name of the *bulena*; but he distinguishes it from the common whale by its smaller size, and having teeth in both the jaws; and his account of the teeth of this fish differs from that of Linnaeus and Artedius. According to him there are thirty in each jaw; those before are blunt, round, and slender; the farthest sharp and thick; between each is a space adapted to receive the teeth of the opposite jaw, when the mouth is closed. Paulus Jovius calls it also *capitulus*. These are all the names it is known by; and that of *VORPES* is sometimes ignorantly given to it, but properly belongs to another species of the same genus, the *PHOCENA*.

The spot-hole of this fish is in the neck; the situation and number of the fins agree with the dolphin; the colour of the back is black, but on each shoulder is a large white spot, the sides marbled with black and white, and the belly of a snowy whiteness; its length is from fifteen to twenty-five feet, and it is remarkably thick in proportion to its length. This fish is extremely voracious, destroys the porpoise, and is said to be a great enemy to the whale, fastening on it like a dog on a bull, till it roars with pain. The *grampus* is sometimes found on our coasts, but most abundant off the North Cape in Norway. Pennant.

GRANA nigra, in the *Materia Medica*, the fruit of a species of *RICINUS*.

GRANA paradisi, or greater *CARDAMOM*, are the seeds of the *AMOMUM* of Linnaeus.

GRANA regia, in the *Materia Medica*, the seeds of the common *RICINUS*, called by some *PERADEX Græci*.

GRANADIER, GRENADIER, or *GRANADIER*, a soldier who is armed with a firelock, bayonet, and lance; a pouch full of hand-grenades to be thrown against the enemy, and a cartridge-box that will hold ten cartridges round. They wear a high cap, lined with cloth with a piece of brass, but now with iron, and a piece of cloth upon their shoulders, called a wing. They were first established in France in 1667, and soon after taken into companies: they were first known in England in 1681. There are companies of *foot granadiers*, and *horse granadiers*, or *granadiers of horse*, by the French called *granadiers*.

badiers volants, or *flying grenadiers*, who are mounted on horseback, but fight on foot and on horseback. These were first established in France by Lewis XIV. in 1676, and formed into squadrons.

Every battalion of foot, of late years, has generally a company of *grenadiers* belonging to it; or else four or five *grenadiers* belonging to each company of the battalion; which, on occasion, are drawn out, and form a company of themselves. These generally take the right of the battalion; and are the first in attacks.

We have in England two troops of *half-grenadier* guards; the first raised in the year 1693, and the second in 1702.

GRANADILLA. See *PASSION FRUIT*.

GRANADO, GRANADA, or GRANADE, in the *Military Art*, a hollow ball or shell, of iron, brass, or even glass, or pewter earthen, filled with gunpowder, and fitted with a fuse to give it fire.

The name *granado* takes its title hence, that it is filled with grains of powder, as a pomegranate is with kernels.

Of these there are two kinds; the one large, the other small: the first are to be thrown at the enemy by a mortar, properly called *BOMBS*, or *SHELLS*. The latter to be cast with the hand, and thence denominated *hand-granades*.

The best way, Calisir observes, to secure a man's self from the effect of a *granado*, is, to lie flat down on the ground, before it burst.

The common, or hand *granado*, is a little, hollow ball of iron, tin, wood, palleboard, or other matter, filled with strong powder, lighted with a fuse, and thus thrown by hand into places where men stand thick; and particularly into trenches and lodgements.

Their composition is the same with that of *BOMBS*; which see. For size, they are usually between two and three inches in diameter, about the bigness of a common iron bullet, and weigh about three pounds: as to dimensions, they are commonly in thickness one eighth, one ninth, or one tenth of their diameter; their aperture, or orifice about a wide, as prescribed by Calisir.

Thunius observes, that the first time *granades* were used, was at the siege of Wachtendonck, a town near Guelde; and that the inventor was an inhabitant of Venlo; who, in making an experiment of the effect thereof, occasioned two-thirds of that city to be burnt, the fire being kindled by the fall of a *granado*.

Bombs were known long before the invention of *granades*. The ancients had a sort of olive, or serepot, somewhat of the same nature with our *granades*, but they were much less perfect.

Calisir mentions a sort of *kind granades*, without any aperture, or fuse, as not needing to be lighted; but being thrown with a mortar, take fire of themselves whenever they fall on any hard solid object.

GRANARY, a building to lay or store corn in, particularly for keeping.

Sir Henry Wotton advises, to make it look towards the north, as much as may be; because that quarter is moist cool and temperate.

Mr. Worlidge observes, that the best *granaries* are built of brick, with quarters of timber wrought in the inside, whereto to nail the boards, with which the inside of the *granary* must be lined to close to the bricks, that there be no room for vermin to shelter themselves. There may be many stories one above another, which should be near to one another; for the shallower corn lies, the better, and it is the easier turned.

Some have had two *granaries*, the one above the other, and filled the upper with wheat, or other corn; this upper one had a fine hole in the floor, by which the corn descended into the lower one, like the sand in an hour-glass; and when it was all come down into the lower *granary*, it was then carried up again into the upper one; and so it was kept continually in motion: which is a great preservation to the corn. A large *granary*, full of square wooden pipes, may also keep corn from heating.

In the care of public *granaries*, or magazines of corn, one great caution necessary, is, the laying up in them such corn as will be least subject to decay; and the single thing to be considered in this, is the laying up only such as is the product of hot and dry countries. In France the corn of the southern provinces keeps many years longer than that of the other parts of the kingdom; and ancient and modern history both inform us, that the corn which is the produce of Africa, particularly of the country about Algiers and Tunis, will keep much longer than that of any other country. The Romans, in old time, annually imported vast quantities of corn from Egypt: this they found not only to produce much larger crops than such as was the produce of their own country, but

to keep many years in their public *granaries* without injury. The Marquis of Santa Cruz, the author of many excellent observations on the politic and military state of different nations, observes, that in Gallia and the Asturias the corn will hardly keep in the *granaries* from one year to another, and that it is the humidity it contains that rots and decays it; and that the corn brought from Castile will keep good many years. This corn, he tells, is the only kind they ever venture to lay up in the public *granaries* of Spain; and that the whole difference between this and the other, is, that it grows in a country where there is less rain in summer. Des Landes Traite Phys.

It would be easy to import corn from Barbary in sufficient quantity for all the feed-corn of the kingdom; and in countries where the people are subject to famine, even for the support of the nation; and the advantage this African corn would have over the European, would be much greater than that of Castile is observed to have over the produce of the other parts of Spain. Flat bottomed vessels, of considerable burthen, yet not made to draw much water, would be very proper for this sort of service; and the voyage through the Straights of Gibraltar would, at a proper season of the year, be short, and performed at a small expence. We might thus be furnished with feed-corn, vastly better than any we can purchase at present; and France with corn that would guard sufficiently against the miseries of a famine, which a long war generally brings upon that nation; and if the public magazines for receiving and laying up this corn, were erected near the mouths of the several larger rivers, the water-carriage would easily dispense it in time of want to all parts of the kingdom.

The kingdoms of Fez and Morocco might be also as good martts for us, though the French are forbid trading for corn in them, on any other condition than that of exchanging military stores for them, which they make a point of it not to do. The keeping up a good understanding with Algiers and Tunis, is however of so much consequence to us, that we do not scruple purchasing their friendship at this price; and we therefore might, if we pleased, as well traffic for corn with fire-arms in Fez and Morocco, as with any other the commodities of our country.

The choice of the *grain* being made, and the manner of procuring it regulated, the next consideration is how to preserve it for this purpose, we have the concurrent testimony both of the ancients and moderns, that subterranean caverns, made in a dry soil, and preserved from the ingress of the damp air, are the properest places. Pliny tells us, that in his time they kept corn a long time in this sort of store-rooms, covering the bottom with straw, and laying upon that the corn in the ear. We find that corn will be preserved thus very well, for five, six, or seven years. And an accident, some years ago, discovered a parcel of corn thus preserved at Amiens, which, though it had been laid up a great number of years, was found to be fresh and good, not worm eaten, nor rotten, nor even mouldy. This is certainly owing to the moist air having been kept out, and with it the eggs of animals, and seeds of those minute vegetables, which we see in form of mouldiness on such corn, as has been less carefully defended from the access of them. Experimental philosophy has proved, that the air is the great source of corruption; keep out that, and all is kept out; and the most corruptible substances, such as meat, butter, milk, and the like, have been preserved fresh four months in the exhausted receiver of an air-pump.

The only objection to this scheme for public *granaries* is the expence, but it is not proper that any but a monarch should undertake them; and there does not appear any way in which the public money could be better employed, than in so general a good. They have near Grand Cairo a magazine of this kind, defended with good walls, and called Joseph's *granaries*. It is not probable, that they are quite so old as the days of that patriarch, but they abundantly prove the utility of such storehouses, by the vast quantities of *grain* annually preserved in them. Many parts of Africa abound with *granaries* of this kind. There are so many deep pits made in the solid rock, the descent into them is but just large enough for a man to go down into them by, but they grow larger as soon as the person is in, and are usually square, and from thirty to forty feet in diameter. In these the great men of the country preserve their corn; they first strew over the floor with straw, then they lay the corn on; still as the heap rises, placing a thin bed of straw between the corn and the sides, as they did at the bottom. In this manner they proceed till the whole cavity is filled: when this is done, they cover the mouth of the entrance with a sort of hurdle of green boughs of trees, Intervient

interwoven one with another. This they cover with about two feet thickness of sand, and over this they raise a ridge of earth, well beat together, in order to throw off the rain both ways, that none may settle on the place and sink into the magazine.

The corn thus stored up always keeps three, four, or more years very good; and not unfrequently, the proprietor being taken off by the feverity of the eastern governments, under which they live, the magazine is forgotten, and some accident discovering it many years afterwards, the corn is almost always found perfectly good in it. All the care they take, in regard to the corn, is to expose it two or three days to the sun's heat, to dry it thoroughly before they carry it into the magazine.

In the duchy of Lithuania, and in the Ukraine, the people always preserve their corn in the same manner in wells or pits made in dry places; but in these countries great care is to be taken in the opening these store-rooms; for if people descend into them, before they have had sufficient communication with the fresh air, they are often killed by the damp, this, however, is easily guarded against; and by these and numerous other instances of the practice of other countries, it appears evident, that the advantage of these subterranean granaries over all others is very great.

Though these are to be recommended before all others, yet the common granaries may, with proper care, be rendered much more useful than they are at present. The great caution necessary to this purpose is to guard against the too great humidity, which these always is in places, where there is a great number of doors and windows. A too free access of the external air is also to be carefully guarded against; for this brings in with it the eggs of a vast number of different insects, which prey upon and destroy the corn. A third caution is, when the corn is the produce of the country, where it is preserved, not to fill the place with the crop of one place only, but to mix the harvests of two or three different provinces as may be, the one dry, the other moist, or otherwise differing as much as may be; thus the contrary qualities of the one will prevent the destruction of the other. There are the three great rules to prevent the corruption of corn; but when the mischief is once begun, it will prove very difficult to stop it; all the care that can be employed should therefore be taken in regard to these.

The two great cautions to be observed in the creeling of granaries are to make them sufficiently strong, and to expose them to the moist drying winds. The ordering of the corn in many parts of England, particularly in Kent, is thus: to separate it from dust and other impurities after it is thrashed, they toss it with shovels from one end to the other of a long and large room, the lighter substances fall down in the middle of the room, and the corn only is carried from side to side, or end to end of it. After this they screen the corn, and then bringing it into the granaries, it is spread about half a foot thick, and turned from time to time about twice in a week; once a week they also repeat the screening it. This sort of management they continue about two months, and after that they lay it a foot thick for two months more, and in this time they turn it once a week, or twice, if the season be damp; and now and then screen it again. After about five or six months they raise it to two feet thickness in the heaps, and then they turn it once or twice in a month, and screen it now and then. After a year, they lay it two and a half, or three feet deep, and turn it once in three weeks or a month, and screen it proportionally. When it has lain two years, or more, they turn it once in two months, and screen it once a quarter, and how long soever it is kept, the oftener the turning and screening is repeated, the better the grain will be found to keep.

It is proper to leave an area of a yard wide on every side of the heap of corn, and other empty spaces, into which they turn and toss the corn as often as they find occasion. In Kent they make two square holes at each end of the floor, and one round in the middle, by means of which they throw the corn out of the upper into the lower rooms, and so up again, to turn and air it the better. Their screens are made with two partitions, to separate the dust from the corn, which falls into a bag, and when sufficiently fall this is thrown away, the pure and good corn remaining behind.

Corn has by these means been kept in our granaries thirty years; and it is observed, that the longer it is kept the more flour it yields in proportion to the corn, and the purer and whiter the bread is, the superfluous humidity only evaporating in the keeping. At Zurich, in Switzerland, they keep corn eighty years, or longer, by the same sort of methods.

The public granaries at Dantzick are seven, eight, or nine stories high, having a funnel in the middle of every floor to let down the corn from one to another. They are built so securely, that though every way surrounded with water the corn contracts no damp, and the vessels have the convenience of coming up to the walls for their lading. The Russians preserve their corn in subterranean granaries of the figure of a funnel-shaped, wide below and narrow at top: the sides are well plastered, and the top covered with stones. They are very careful to have the corn well dried before it is laid into these floors, houses, and often dry it by means of ovens, the summer dry weather being too short to effect it sufficiently. Dantzick is the grand storehouse, or repository of all the fruitful kingdom of Poland. The wheat, barley, and rye, of a great part of the country, are there laid up in parcels of twenty, thirty, or fifty lasts in a chamber, according to the size of the room; and this they keep turning every day or two, to keep it sweet and fit for shipping. A thunder storm has sometimes been of very terrible consequences to these floors. All the corn of the growth of former years having been found so much altered by one night's thunder, that though over-night it was dry, fit for shipping or keeping, and proper for use of any sort, yet in the morning it was found clammy and stinking. In this case there is no remedy, but the turning all such corn three or four times a day for two months or longer; in which time it will sometimes come to itself, though sometimes not.

This effect of thunder and lightning is only observed to take place in such corn as is not a year old, or has not been threshed thoroughly in the straw before it was thrashed out. The latter inconvenience is easily prevented by a timely care; but as to the former, all that can be done is carefully to examine all floors of the last year's corn after every thunder storm, that if any of this have been so affected, it may be cured in time; for a neglect of turning will certainly utterly destroy it. Phil. Trans. N° 25, or Abr. vol. ii. p. 629, &c.

According to Vitruvius's rules, a granary should always be at the top of a house, and have its openings only to the north or east, that the corn may not be exposed to the damp winds from the south and west, which are very destructive to it; whereas the contrary ones are very necessary and wholesome to it, serving to cool and dry it from all external humidity, from whatever cause. There must also be openings in the roof to be set open in dry weather, partly to let in fresh air, and partly to let out the warm effluvia which are often emitted by the corn. The covering of the roofs should always be of tiles, because in the worst seasons, when the other openings cannot be safe, there will always be a considerable inlet for fresh air, and a way out for the vapours by their joints, which are never close. If there happen to be any windows to the south, great care must be taken to shut them up in moist weather, and in the time of the hot southern winds.

There must never be a cellar, or any other damp place, under a granary, nor should it ever be built over stables; for in either of these cases the corn will certainly suffer by the vapours, and be made damp in one, and ill-tasted in the other. Mem. Acad. Par. 1768.

Mons. Du Hamel and Dr. Hales recommend various contrivances for ventilating or blowing fresh air through corn, laid up in granaries, or ships, in order to preserve it sweet and dry, and to prevent its being devoured by weevils or other insects. This may be done by nailing wooden bars or laths on the floors of the granary, about an inch distant from each other, when they are covered with hair-cloth only; or at the distance of two or three inches, when coarse wire-work, or basket-work of eier is laid under the hair-cloth, or when an iron-plate full of holes is laid upon them. These laths may be laid across other laths, nailed at the distance of fifteen inches, and two or more deep, that there may be a free passage for the air under them. The under laths must come about six inches short of the wall of the granary at one end of them; on which end a board is to be set edgewise, and sloping against the wall; by this disposition a large air-pipe is formed, which having an open communication with all the interstices between and under the bars, will admit the passage of air below, freely through a hole at the extremity of it, and all the corn in the granary, that will consequently carry off all the exhalations of the corn. The venturings the fresh air may be fixed against the wall, on the inside or outside of the granary; or under the floor or in the ceiling; but wherever they are fixed, the handle of the lever that works them must be out of the granary, otherwise the person who works them would be in danger of suffocation, when the corn is fumed with burning brimstone, as is sometimes done for destroying weevils.

Small moveable ventilators will answer the purpose for ventilating corn in large bins in *granaries*, and may be easily moved from one bin to another. If the *granary* or corn-bin be very long, the main air-pipe may pass lengthwise along the middle of it, and convey air, on both sides, under the corn. In large *granaries*, large double ventilators, laid on each other, may be fixed at the middle and near the top of the *granary*, that they may be worked by a wind-mill fixed on the roof of the building, or by a water-mill. The air is to be conveyed from the ventilators through a large trunk or trunks, reaching down through the several floors to the bottom of the *granary*, with branching trunks to each floor, by means of which the air may be made to pass into a large trunk along the adjoining cross-walls: from these trunks several other trunks, about four inches wide, are to branch off, at the distance of three or four feet from each other, which are to reach through the whole length of the *granary*, and their farther end are to be closed: seams of one-tenth or one-twelfth of an inch are to be left open at the four joinings of the boards, where they are nailed together, that the air may pass through them into the corn. In some of these lesser trunks there may be sliding shutters, in order to stop the passage of the air through those trunks which are not covered with corn; or to ventilate one part of the *granary* more briskly than others, as there may be occasion. There must also be wooden shutters, hung on hinges at their upper part, so as to shut close of themselves: these must be fixed to the openings of the walls of the *granary* on their outside: by these means they will readily open to give a free passage for the ventilating air, which ascends through the corn, to pass off, but will instantly shut when the ventilator ceases, and thereby prevent any dampness of the exterior air from entering: to prevent this, the ventilation should be made only in the middle of dry days, unless the corn, when first put in, is cold and damp.

In lesser *granaries*, where the ventilators must be worked by hand, if these *granaries* stand on staddles, so as to have their lower floors at some distance from the ground, the ventilators may be fixed under the lowest floor, between the staddles, so as to be worked by men standing on the ground, without or within the *granary*. A very commodious and cheap ventilation may be made for small *granaries*, by making a ventilator of the door of the *granary*, which may be easily done by making a circular screen, at the face of a quarter of a circle, behind the door: but in order to this, the door must be open, not inwards but outwards of the *granary*, so that as it falls back, it may be worked to and fro in the screen: which must be easily adapted to it in all parts of the circular side of the screen, as well as at the top and bottom. That there must be a stop at about eight or ten inches distance from the wall, to prevent the door's falling back farther: that there may be room for a valve in the screen to supply it with air, which air will be driven in by the door, through a hole made in the wall near the floor, into the main air-trunk, in which there must be another valve over the hole in the wall, to prevent the return of the air. See on this subject, and the advantages of ventilating different sorts of grain, Hales's *Uses of Ventilators*, part i. p. 81, &c. part ii. p. 220, &c. See VENTILATOR.

GRANATARIUS, in *Mediæ Aevi* Writers, an officer in monasteries who took care of the provisions.

GRANATE, popularly called **GARNET**, in *Natural History*, a gem, or precious stone, of a high red colour: thus called from the resemblance it bears to that of the kernel of a pomegranate.

Garnets are either *oriental*, or *occidental*: the first are brought from divers parts of the East Indies; the second from Spain, Bohemia, and Silesia.

Those from the East, are distinguished by their colour into three kinds: the first, of a deep brownish red, like black clotted blood; of which kind there are some as big as an hen's egg: the second are nearly of the colour of a hyacinth, with which it were easy to confound them, but for their deeper redness. The last having a mixture of violet with their red, are called by the Italians, *rubini della rube*.

The *occidental garnets* are of divers reds, according to the places they are found in. Those of Spain imitate the colour of the kernel of a pomegranate: those of Bohemia have a golden cast with their red, glittering like a live coal: those of Silesia are the darkest of all, and seldom thoroughly transparent.

Of the *occidental garnets*, those of Bohemia are the most valued: some even give them the preference to the oriental kind. They are found near Prague; not in any particular mines, but picked up by peasants in the fields, from among the sands and pebbles.

This is a gem very subject to faults and blemishes, and

is of different degrees of colour in its different specimens, and when perfectly pure and well coloured, it is little inferior to the ruby in beauty.

This gem is the eighth place in hardness from diamonds, and fusible by fire. It is found of various sizes, from that of a large pin's head, to an inch in diameter; but such large ones are very rare, the largest of these usually found not exceeding a fifth of that size. It is almost always found oblong, or of an irregularly rounded and pebble-like figure and never in angular columns. Its surfaces, which are sometimes flat, and sometimes more, are never so naturally smooth and polished as those of the ruby are, and its colour is a strong red, which taken in different lights, never fails to show the bluish cast. Its degree of colour is very different in the different specimens, and it wants much of the brightness of the ruby, as well in its polished as in its native or rough state. These are the determinate characters by which the *garnet* is to be known from all the other red gems. Among our lapidaries and jewellers, genuine *garnets*, according to their different degrees of colour, are known by three different names. 1. The *parrot*, simply so called; this is the finest and most valuable kind. It is of a very deep blood-red, with a faint admixture of blue. 2. The *ruby*, This is the name they very improperly give to the *garnet*, when it is of a very strong but not deep red, and has a fairer cast of the blue. This, when pure and perfect, is an extremely elegant gem. 3. The *rose*, or as they speak it, the *rose-garnet*. This is the name by which they call those *garnets*, which are of a yet brighter red, approaching to the colour of native cinnamon, with a faint tinge of blue. 4. The *almandine*. This is the name given to the *garnet* when of the same admixture of tinge with what they call the rock-ruby, but only a little paler. Hill's *Hist. of Foss.* p. 531.

These are the names by which the most expert among our jewellers distinguish the various appearances of the *garnet*; and which, though to the naturalist they are but varieties of the same stone, yet are to them different species of gems, since they are of several different values. But among the less judicious of the artificers, the names are strangely confounded with one another, and even with different stones of other kinds; the blues sometimes being by some of them called *jacobs-stones*, and the deeper hyacinths *forane-garnets*.

The ancients, though they have not distinguished this gem by any peculiar name, yet seem to have been very well acquainted with it, and mention its several appearances, as to its different degrees of colour, as to many species of the carbuncle, the common name by which they called all the red gems; and their *marinus*, *iodolite*, and *manducare*, seem to have been only varieties of it.

Some authors, of very distinguishing judgement, have taken the deeper *parrot* to be the very species of gem known by the name carbuncle by Theophrastus; but on comparing the two stones together, it appears plain, that the *parrot*, whose colour goes off into a blue, could never give them the idea of a lighted charcoal, or make to trace a fire-colour in the sun as the carbuncle, whose deep red goes off into a scarlet.

Croustede forms a distinct order of the *garnets* and the *basaltes*, which he calls *serpentine-garnets*. The distinguishing property of these *garnets* is, that they are more fusible in proportion as they contain less metallic matter, and are more transparent and glassy in their texture. In other respects they resemble the siliceous order of earths. All *garnets* contain iron; most of them contain tin also, and some are said to contain iron and lead. The *garnet* is of some use in medicine: its powder is sometimes an ingredient in the cordial electaries. The ancients held it excellent against heaviness and melancholy.

GRANATE paste. The counterfeited *garnet* in paste, is formed with three different proportions of the ingredients, which are these:

Take prepared crystal two ounces, common red-lead six ounces, manganese sixteen grains, saffron three grains; mix all well together, and put them into a crucible; cover it with a lute, and set it in a potter's kiln for twenty-four hours.

Or, take crystal two ounces, minium five ounces and a half, manganese sixteen grains, saffron four grains; mix them well together, and leave room for their swelling in the pot; bake them twenty-four hours in a potter's kiln. The last method is this: take crystal prepared two ounces, minium five ounces; mix them, and add manganese fifty-two grains, saffron six grains; mix them well together, and let all be baked, in a pot well luted, in a potter's kiln for twenty-four hours.

The first of these makes a very handsome *garnet* of the common tinge; the second, a deep one, with something

of a violet tinge, as many of the natural *granites* have; but the third makes much the finest and brightest. *See* ART OF GLASS, p. 124. *See* GLASS AND PASTE.

GRAND, a term rather French than English, though used on many occasions in our language. It has the same import with *great*, being formed of the Latin *grandis*.

In this sense we say, the *grand* master of an order, the *grand* master of Malta, of the free-masons, &c. So also, the *grand* lignist, the *grand* vicar, &c. *grand* father, *grand*mother, &c.

In the French polity and customs there are divers officers thus denominated, which we frequently retain in English, as *grand* almoner, *grand* écuyer, *grand* chambellan, *grand* viceroy, &c.

GRAND *style*. *See* ARCHT.

GRAND *lape*. *See* CAPE AND ATTACHMENT.

GRAND *day*. *See* DAY, in LAW.

GRAND *assize*, *assise*, *assizes*, a writ of assize, is called on account of its extent, which reaches to all the goods and chattels of the party within the county.

This writ lies in two cases; either when the tenant or defendant is attainted and appears not, but makes default; or where the tenant or defendant hath once appeared, and after makes default. On such occasions, this writ lies by common law, in lieu of a petit assize.

GRAND *dessein*, in *Architecture*, the name given by Winslow, and the other French anatomists to the muscle generally called *testaceous shell*; by some the *unisculptor* and *unsculpter*, and by Vitellius *quarta humor*.

GRAND *style* is a term used by painters, to express that there is something in the picture very great and extraordinary, calculated to surprise, please, and instruct.

Where this is found, they say, the painter was a man of *grand* style, and they use the words sublime and marvellous, when they speak of a picture, in much the same sense.

GRAND *clerc*, *guard*, *jur*, *lary*, *priser*, *premier* of France, *jurament*. *See* ELIXIR, GUARD, &c.

GRANDEE is understood of a lord of the first rank or prime quality.

In Spain, the term *gran* is used absolutely to denote the prime lords of the court, to whom the king has once given leave to be covered in his presence; there are some *grandes* for life only; made by the king's laying hands, by the king's laying. Others are *grandes* by descent; made by the king's laying. Be covered for thyself and heirs. These last are reputed far above the former.

There are some who have three or four *grandeships* in their family.

GRANDGO is used in Scotland for the pox. In the Philosophical Transactions, N^o 460. sect. 5. we have a proclamation of king James the 6th of Scotland, ordering all who had this disease, or who had attended others under it, forthwith to repair to an island in the Firth of Forth. If the *grandgo* was the pox, and this disclaimer came into Europe at the siege of Naples in 1656, it must have made a very quick progress to cause such an alarm at Edinburgh in 1657.

GRANDO, in *Natural History*, a stone more usually called *CHALAZIA*.

GRANGE, an ancient term for a barn, or place, wherein to lay up and thresh corn.

The word is formed of the Latin *granum*; or of *granum*, *grain*, *corn*, &c. Hence also *granger* or *grangier*, a *grangekeeper* or *farmer*.

GRANGE is also used, in a more extensive sense, for a whole farm, with all the appendages of stables for horses, stalls for cattle, &c. and for an inn.

GRANI, in our Ancient *Writers*, multichokes or whickers of a beard.

The word seems formed from the ancient British or Irish, *grain*, a beard.

It is given for a reason why the cup is refused to the lady, *Quia barba, et pilosus habet granum, domi prebent inter pilos famuli, prius liquore pili infundit, quam uti infundant.*

GRANITES, in *Natural History*, are defined to be stones composed of separate and very large concretions, rudely compacted together, so as not to form one mass or substance, like marble, but to remain distinct from each other, of great hardness, giving fire with steel, not fermenting with acids, and slowly calcining in a strong fire.

The parts of which the *granites* consist are not homogeneous, but are composed of common quartz, felspar or rhomboidal quartz, and of mica, with which are also often accidentally mixed particles of other stones and metallic earths. From this granitic structure, they derive their name *granites*, i. e. *granis compacts*. Some writers in mineralogy have injudiciously made the *granite* either a variety or species of the *porphyry*; and others have given the name of *granite* to all marbles, variegated with red, black, yellow, &c. spots, merely on account of their being speckled marbles.

The species of this genus are the following: 1. The *granite* with a black ground, having a slight tincture of green spotted with white; nodules of this are frequent on most of our English shores, and large masses of it abound in the pavements of the streets of London.

2. The black and white *granite*, called *moon-stone*. 3. The *granite* with a dusky white ground, irregularly and thickly spotted with small black spots: this stone takes a very fine polish and surface; it is called by the Italians *granito*, and by modern travellers the *granite*; there are great quantities of it found in the ancient temples and other buildings of Egypt, Asia, and Italy; and there is scarce an island in the Archipelago that does not abound with it: the most common *granite* of Europe is of this species; there are large quarries of it in the provinces of Normandy and Provence in France, where it is used for door-cases and chimney-pieces.

4. The white *granite*, with a few black spots, found in nodules and masses on many of the shores of Europe. 5. The white *granite* with large green spots; this is a beautiful species, and takes a fine polish and surface: there are strata or masses of this *granite* in the county of Downe in Ireland, especially about Newry, which town is partly built with this stone. 6. The red, black, and white *granite*, commonly known by the name of oriental *granite*.

The oriental *granite* of the moderns is the stone described by the ancients under the name of *porphyry* and *hyacinth*, and from its extreme hardness and beauty has been always greatly esteemed. It is, when in its rough state, a very rude, coarse, and irregular mass, but of a very firm and compact structure, and is of a very beautiful pale red, variegated with white and black; the red parts are of an irregular structure and marbled appearance.

The white are tabular, or composed of flat concretions, and many of them are very bright and pellucid, others of rough surfaces and semi-opaque; the former are composed of a talcy, the latter of an earthy crystal. The black parts are plainly foliaceous, and are composed of the black crystalline talc. And beside these, there are, in different parts of the stone, many flakes both of black and white unaltered talc. The whole is of a very singular hardness, but takes an extremely elegant and beautiful polish.

There are many varieties of this oriental *granite*: the true oriental red *granite*, of which the temples, obelisks, and other ancient buildings that abound in Egypt, Asia, and Italy, were built, was procured from Upper Egypt, and particularly from Syene in the Theban; the quarries in this place have been described by Dr. Pococke, in his Description of the East, vol. 1. p. 137. The whole country of Arabia Petrea is a mass of *granite*; and this red *granite* is also found in many parts of Europe; there are many fine tables, &c. equal to the finest oriental *granite*, at mount Edgemoor in Devonshire, which have been wrought from stone found in those parts. Masses of this stone are likewise found in many other counties of England.

The whitish red *granite*, which is sometimes found in large strata, but more frequently in large loose nodules, is a variety of the same species. It is very plentiful in many parts of the island of Minorca, from whence we might have it in abundance, and it would make very beautiful tables, &c. The rough masses of it are sometimes found also on the shores of our island of Guernsey, whence they are taken up for ballast for ships, and are sometimes by this means brought among us, and used in the pavements of our streets.

7. The *granite* of a pale yellowish colour, spotted with small irregular black spots: this is a rare species; but some masses of it are found in the county of Donegal, in Ireland; and there are pillars of it at Constantinople, and a colossal statue twelve feet high near Thebes in Upper Egypt, mentioned by Pococke *ubi supra*, p. 103. 8. The *granite* of a fine grass-green colour, thickly spotted with black: this is a rare but elegant fossil; small nodules of it are sometimes found on our shores; and *granite* of this species is also found near Sienna in Italy.

Hill's Foss. p. 468, &c. Min. de Colla's Foss. p. 273, &c. **GRANIVOROUS**, an epithet or denomination given to such animals as feed upon corn, or any other grain or seeds.

Granivorous animals are chiefly of the *bird* kind. There have a peculiar provision for the digesting of so dry and hard a food.

GRANT, in LAW, a gift in writing of something incorporeal, not lying in livery, and which cannot apply be passed or conveyed by word only; as a lease, annuity, service, advowson in gross, cyress, &c.

Or, it is a gift made by such persons as are not the lord by deed; as the king, and all bodies politic. *See* DONATION.

This difference is often, in speech, neglected; and the word *grant* taken generally for any gift whatsoever, made of anything, by any person.

In this sense, he that granteth is named *grantor*; and he to whom it is made, the *grantee*.
A thing is said to lie in *gravel*, which cannot be assigned without deed.

GRANULATED *sil.* See OIL.

GRANULATION, in *Chemistry*, an operation performed on metals, whereby they are reduced into small grains or globules.

It is done by melting them, and when in fusion, casting them from a certain height into cold water; in which they congeal into granules, as required, and are hereby rendered more easy to be dissolved. The best way is to pour the fluid metal through a colander, or a new burlen broom, or to agitate the water with the broom, thus giving it a circular motion whilst the metal is poured in. Copper is *granulated* for making brass in a cylindrical wooden reservoir, four or five feet deep, in which a circular brass or copper bottom may be raised or lowered by means of a chain. The reservoir is covered with a copper lid, in the middle of which is a hole half a foot in diameter, intended to receive an iron plate pierced with holes and coated with clay. The reservoir being filled with water, the melted copper is poured through the holes in the lid into the water; where it is broken by its fall into smaller drops or grains, rendered solid by the cold water, and collected in the moveable bottom, which is raised by the annexed chain, that the *granulated* copper may be taken out. *Matquery, Dict. Chem. Eng. edn. art. Brûle.*

Lead, tin, and brass, which are very brittle, when they are so hot as to be almost fused, may be *granulated* by pouring them, in a state of fusion, into a box, the inner surface of which is rubbed with powdered chalk, and by shaking the box the metals in the box are no sooner become solid, and consequently very brittle, than they are dissolved, by being rubbed against the sides of the vessel into a fine dust. Silver and gold, and the more refractory metals, must be *granulated* in either of the first methods above mentioned with water. *Cramer, Art of Ass. p. 70.*

The term *granulated* is also applied to *gun-grinder*.

GRANULOSE *rusti* are those composed of smaller knobs than the *granulose* ones, and resembling to many grains of corn; of this sort is the white chrysalis.

GRANUM *orile*, in *Botany*, a name given by some authors to the turpentine-tree. The fruit of this tree is reddish white unripe; but as it ripens, it becomes of a deep bluish green colour, and hence the name.

GRAPE, the fruit of the vine. See VINE and WINE. See also CUCKERBERRY and RAISIN.

GRAPE hyacinth. See HYACINTH.

GRAPE, *monopetala* or *sea-file*, *excolaba*, a genus of the *Stenandra* tripartita class. Its characters are these: the flower has one permanent petal, which is cut into five segments; it has a fleshy unilobed nectarium which surrounds the germen, and six, seven, or more erect spreading stamens, with an oval germen, which turns to a fleshy berry, including an oval nut, which is wrapped up in the petal of the flower. There are six species, natives of the West Indies, where growing on the sea-coast, they have obtained the name of *sea-file grapes*.

The leaves of these plants continuing in verdure all the year, make a fine appearance in the hot-house in winter; but they do not produce flowers here.

They must be propagated by seeds, sown in pots of light rich earth, and plunged into a hot-bed of tanner's bark: the plant must constantly remain in a stove, being too tender to live in the open air, even in our warmest weather; only in summer they may be frequently refreshed with water, and have fresh air admitted to them. *Miller.*

GRAPE, wolf. See LYCOTAPHYLE.

GRAPE-tail, in *Natural History*, a name given by authors to a species of protuberances resembling clusters of grapes, and when ripe of a reddish colour, which are found hanging from the oak at some seasons of the year. These are genuine galls, though of a peculiar kind, and owe their origin to a very small four-winged black fly. This little creature deposits its eggs either on the surface, or within the substance of those pedicels of the oak which nature has destined for producing the catkins or small flowers of that tree. The hatching and sucking of the worms, which are produced from these, occasion a wrong derivation of the juices to the part; and the consequence of this is, that, instead of flowers, there appears a protuberance over the part where each of these insects is lodged. The tubercle at first is small, and of a pale greenish colour; but it finally becomes yellowish or reddish, and is juicy and large. A number of these standing close together upon the stalk, give the appearance of a cluster of grapes on the bunch; and when any one of these is opened, there is found in it either a worm, a chrysalis, or a fly, the animal never quitting its habi-

tation till in its perfect state, but passing through all its changes in it. *Reaumur, Hist. Insect. vol. vi. p. 162.*

GRAPE-sha, in *Artillery*, is a combination of small shot, put into a thick canvas bag, and corded strongly together, so as to form a kind of cylinder, whose diameter is equal to that of the ball adapted to the cannon. The number of shot in a *grape* varies according to the service or use of the gun: in sea-service nine is always the number; but by land it is increased to any number of size, from an ounce and a quarter in weight to three or four pounds. In sea-service the bottoms and pins are made of iron, whereas those used by land are of wood.

GRAPE, in the *Marine*, a term used to signify the ARREST or many tumours that happen in a horse's legs.

GRAPHICAL, *perspective*, in *Optics*, is an instrument described by Mr. Martin, consisting of a tube containing two convex lenses, which are placed at twice their focal distance from each other; and in their common focus is another glass, divided into equal parts with the point of a diamond. Though this instrument does not magnify any object, yet the angle under which an object is seen is easily known by it; and once this angle varies with the distance of objects, it is easily applied in the purpose of measuring inaccessible heights and distances; and since the field of view is divided into equal squares, it is useful in drawing the perspective appearance of objects. Moreover, as all foreign light is excluded by the tube in which these lenses are inclosed, pictures seen through it have a fine relief, on which account, and also because objects appear inverted through it, the images of a *camera obscura* are viewed with it to peculiar advantage. If a lens of a greater focal length be fixed at a proper distance from the centre of the tube, this instrument will be a telescope, and will magnify the points which are looked at through it; and if a small lens be used, it will be a microscope, and the same microscope will serve for them both. *Martin's Optics, chap. xvii. p. 280, &c.*

GRAPHIDA, in *Natural History*, a name by which some authors have called the *MONOCENTRUS*, or French chalk.

GRAPHISCUS, in the *Writings of the Animals*, a name given to an instrument used for extracting dirt from wounds. It is said to have been the invention of Diocles, and is described by Celsus.

GRAPHOIDES, or *GRAPHIODES*, *spargosus*, in *Anatomy*, an appendage of the bones of the temples, long, small, sharp, and a little crooked, like a cock's spur; called also *stylus*.

The same name is sometimes also applied to the muscular digastricus.

Likewise to an extension of the brain, resembling a writing pen.

GRAPHOMETER, a name which some authors, particularly the French, give to a surveying instrument, by us commonly called a *SEXTANT*.

GRAPPLINGS, in a Ship. See GRAPNEL.

GRAPNEL, or *GRAPPEL*, on *Ship-board*, a kind of small anchor for boats or galleys to ride by. It differs from other anchors, as having four or five flukes and no snook, though there are some with three flukes, with which they use to sweep for lawlers or small cables. In men of war also, the *grapnel*, or at least a higher kind of them, whose flukes are furnished with strong barbs on their points, are used to be thrown into an enemy's ship, in order to catch hold of some of her gratings, rails, gun-wales, &c. this is done in order to boarding of her. They are particularly useful in *fire-ships*, and called *fire-grapplings*.

GRAPPLE, in the *Marine*. A hook is said to *grapple* with one or both legs, when he catches or raises them more hastily and higher than ordinary, as if he were converting.

GRASS, *gramen*, in *Botany*. To enumerate all the species of grass which are found growing naturally in England, would greatly exceed the bounds which can be allowed for this article; it will suffice, therefore, to mention a few species, which are either used in medicine, or cultivated as a pabulum for cattle; for there is scarcely a pasture in this country where great numbers of different species are not to be found intermixed. Mr. Ray has ranged them in the following order, viz. wheat-grass, rye-grass, datch-grass, panicle-grass, canary-grass, foxtail-grass, cat-tail-grass, hedge-hog-grass, scab-grass, oat-grass, cock's-foot-grass, buck-grass, and miller-grass. These and other *grasses* Linnaeus has arranged into distinct genera.

The common creeping *grass* with a spike like wheat, called dog or couch-grass, which is a species of the *TRITICUM* in the Linnaean system, has a creeping root which spreads far in the ground, and is a very troublesome weed in gardens and arable land. The common method of destroying it in the former, is to fork out the roots as often

often as the blade appears above ground; where this is two or three times carefully repeated, it may be totally rooted out; but when the surface of the ground is very full of the roots of this grass, the shortest way of destroying it is to trench the ground two spits and a shovelling deep, turning all the couch to the bottom, where it will rot and never shoot up; but in shallow soils, the roots cannot be buried so deep as to lie below the depths at which they naturally shoot.

Where the roots of this grass get possession of arable fields, the usual method of eradicating it is by laying the land fallow in summer, and frequently harrowing it well to draw out the roots; where this is carefully practised, the ground may be well cleaned in one summer, that the roots cannot much injure the crop which may be sown upon it; but such land should be sown with articles which require the horse-shoeing culture; for where the land can be frequently tilled or harrowed afterward, it will be of great service in cleaning it from the roots of this grass and other bad weeds. The blade of this grass is so rough that cattle will not feed upon it.

The roots of this couch-grass are used in medicine, and are accounted aperitive and diuretic, opening obstructions in the reins and bladder, promoting urine, and are of service against the gravel and stone. The juice of the leaves and stalks was greatly esteemed by Dr. Boerhaave, who generally prescribed it in all cases where he supposed there were any obstructions in the urinary ducts.

The *harrel* with a chaffy spike, commonly called *ray* or *ryegrass*, which is a species of the *LYCUM* in the Linnaean system, is a hardy sort of grass, much esteemed among the farmers for that quality. It will grow on any land, and therefore produces crops where nothing else will. It thrives best of all on four, clayey, and weeping grounds, and equally endures the severest droughts of summer, and frosts of winter, suffering no damage from either. It is the best of all winter feeds for cattle, the shorter it is eaten the better, and it springs the earliest of any. There is no danger of overstocking it, for if it be left to grow too much, the stalk becomes hard and fleshy. It is best for horses and for sheep, and very much prevents the rotting of the latter. The best way of sowing it is with clover. The common quantity of seed is two bushels to an acre, but three bushels are much better; though in some lands, where the clover is likely to succeed very well, they sow eight pounds of cloverseed, and one or two bushels of rye-seed to an acre, and this makes a crop that will last seven or eight years. The species of grass usually cultivated in this manner is called the red *harrel*.

Some mow it as hay, and thresh it for the feed, which, about London, sells from half a crown a bushel to three shillings. Four or five quarters of this feed will be sometimes produced from an acre of the grass. If at any time a field of this grass is found to grow thin, it is only necessary to sown on a bushel of the seed, and roll it with a wooden roller, and the plants arising from this addition will make the whole crop sufficiently thick. Rye-grass has this great advantage, that it kills weeds without any other sown plant; even thistles cannot grow among it. When the rye-grass is cut for hay before it is perfectly ripe, the hay is the better, but the seed will not grow so well. When the seed is newly threshed, it must not be laid too thick, for it is very apt to heat and ferment, and the whole will be spoiled. Mortimer's Husbandry, p. 40.

The meadow grass with large panicles and a narrow leaf, and that sort with a broad leaf, which are species of the *POA* in the Linnaean system, are the two best species of grass for pastures; so that if the seeds of these were carefully collected and sown separately, without any other mixture of grass, there would not only be a greater quantity of feed on the same space of land, but the grass would be better, the hay sweeter, and the verdure more lasting than any other sort; but there requires some attention to the sowing the seed pure without mixture.

The taller meadow out-grass with a yellowish panicle and small husks, which is a species of the *AVENA* of Linnaeus, and the tall meadow rye-grass, are also very good grasses for pastures, and have perennial roots. These are a very tender kind of grass, and their stalks do not become stiff and harsh, like those of some other species; but with proper care may be made very fine, and if daily rolled, the roots will mat and form a very close sward. The greenish quaking grass, or cow-quakes, is mentioned for variety, not for use; this has an annual root. The heads hang by long slender foot-stalks, which being moved by every wind, they generally appear shaking, and gained it the title of quaking grass. See *BETA*.

The cock's foot-grass, capon's tail-grass, and miller grass, are too coarse to deserve attention in England.

The land upon which grass is intended to be sown,

should be well ploughed and cleared from the roots of noxious weeds, especially if the grass is to remain for pasture. Therefore, in places where weeds abound, it will be a good method to plough up the surface in April, and let it lie some time to dry; and then harrow the roots into small heaps and burn them. The ashes so produced will be good manure for the land when spread upon it; but when couch, fern, or rest harrow is in plenty, whole roots run for under ground, the land should be ploughed two or three times, somewhat deep, in dry weather, and the roots be carefully harrowed off after each ploughing, which is the most sure way to destroy them. Where the land is very low, and of a stiff clayey nature, which holds water in winter, it will be of singular service to make some under-ground drains to carry off the wet, which, if long detained on the ground, will render the grass sour.

Before the seed is sown, the surface of the ground should be made fine and level, and the seed should be harrowed in, and the ground rolled with a wooden roller. When the grass comes up, if there should be any bare spots they may be sowed again, and the first kind flowers will bring up the grass and make it very thick. Miller.

GRASS, *arven-sarclat*. See *TRIOLOCHIS*.

GRASS, *lent*. See *AGROSTIS*.

GRASS, *bird*. See *BIRD-GRASS*.

GRASS, *comary*, in *Botany*. See *PHALARIS*.

GRASS, *capon's-tail*. See *FESTUCA*.

GRASS, *cat-tail*. See *PILULABIS*.

GRASS, *cater*. See *TRIOLOCHIS*.

GRASS, *cock's-foot*, *chick-pea*, a genus of the *triantheria dignia* class; the calyx of which is compressed and bivalve.

GRASS, *couch*. See *ERIOCHLOA*.

GRASS, *couch*. See *GRASS SUPRA*.

GRASS, *crisp*. See *DOG-TAIL*.

GRASS, *dog's*. See *GRASS SUPRA*.

GRASS, *hard*, a name sometimes given to the double spiked fescue or rye. See *RYE*.

GRASS, *hog-tail*. See *DOG-TAIL*.

GRASS, *finer*. See *FESTUCA*.

GRASS, *fast-tail*, *alpinum*, in *Botany*, a genus of the *triantheria dignia* class. Its characters are these: the calyx is a glume composed of two valves, and including a single flower; these valves are oval-pointed and hollow; the flower is composed only of one valve, which is hollow, and of the same length with the calyx, and has a long awn or beard inserted on its back part near its base; the filaments are three capillary filaments; the anthers are oblong; the germens of the pistil are roundish; the styles are two in number, hairy, reflex, and exceed the length of the cup; the stigmas are simple; and the flower incloses the seed, which is single and roundish.

GRASS, *gale*. See *ASPEN*.

GRASS, *hart*, *aria*, a genus of the *triantheria dignia* class.

The calyx is of two valves, including a double flower, and the hollow has no separating rudiment.

GRASS, *hard-tail*, *legumin*, a genus of the *triantheria dignia* class. The calyx is composed of two valves, with a downy beard.

GRASS, *hard*, in *Botany*, a name given to several distinct genera of plants. See *KNOT-GRASS*.

GRASS, *hard*, or *quaking* GRASS. See *SUPRA*.

GRASS, *meadow*. See *GRASS SUPRA*.

GRASS, *hard meadow*. See *DOG-TAIL*.

GRASS, *millet*. See *MILLET*.

GRASS, *rat*, a name given to a species of the *FESTUCA*.

GRASS, *panic*. See *PANIC*.

GRASS, of *Parnassus*, *Parnassie*, in *Botany*, a genus of the *pentantheria tetragyna* class. Its characters are these: the flower has a spreading empanclement, cut into five parts, and has five roundish concave petals, which have five heart-shaped concave nectariums, and five filaments terminated by deformed filaments, with a large oval germens having no style, but four obtuse stigmas in their place; the germens turn to an oval four-cornered capsule, with one cell, containing several oblong seeds. There are two species.

GRASS, *pepper*. See *PILULABIS*.

GRASS, *padding*, a name sometimes given to *FENNY-ROYAL*.

GRASS, *quaking*. See *GRASS SUPRA*, and *BRIEA*.

GRASS, *rat*. See *LOUIS-MART*.

GRASS, *rush*. See *RUSH*.

GRASS, *rye*. See *GRASS* and *LOUIS-MART*.

GRASS, *scirpin*. See *CYPERILLABIS*.

GRASS, *sway*. See *SCURVY-GRASS*.

GRASS, *sway*. See *HOBBY-TAIL*.

GRASS, *tick*. See *ALOE* and *DOG-TAIL*.

GRASS, *ward*. See *CORN-FLAG*.

GRASS, *trifol*. See *TRIOLOCHIS*.

GRASS, *vernal*. See *ANTHOTHANUM*.

GRASS, *velvet*. See *CHICKLING VETCH*.

GRASS, *viper*. See VIPER-*grass*.

GRASS, *whitew*. See DEARA.

GRASS, *worm*. See STIGELIA.

GRASS, *wrack*. See ZOSTERA.

See also for other kinds, under LUCERN and SAINTFOIN.

GRASS-plats and walks make a considerable article in Gardening, our turf being, like our gravel, superior to that of any other country.

The common way of making these is by laying on turfs from a common, and the plats thus made are greatly superior to those made by fowing, there being great nicety and art required in bringing the latter to good order, and in procuring the proper seed, that from common hay-lofts being of a mixture of good and bad kinds, and by no means fit for the purpose, as containing the seeds of weeds, as well as very improper grasses.

If the soil be dry, it is best to lay these quite even and level; but if damp, they may be laid a little rounding, but not more than an inch in twenty feet. If the soil is rich, the surface of the ground under the turf should be covered with sand or poor earth, which will keep the grass fine. The oftener these walks are mowed and rolled in summer, the thicker their bottoms will be, and in autumn they should be kept shorter than at any other season, for if the blade runs up high at that season, the bottom will be bare in winter. All grass-walks ought also to be frequently polled, as the gardeners call it: this operation is dispersing the worm-calls all over the walks with long all poles; this, beside destroying the worm-calls, is very beneficial to the growth of the walk. When turf is designed to remain for years without renewing, a dressing of rotten dung, ashes, or rotten tan, should be laid upon it every other year; and these dressings should be laid on early in winter.

In order to low grass, the ground must be dug, then finely and evenly raked over, all the clods and stones taken off, and an inch thickness of good mould sifted on it. This done, the seed must be sown very thick, that the blade may come up close and short; and the ground must be then raked over again, to bury the seed, otherwise, if it should happen to be windy weather, a great part of it may be blown away.

The best season for sowing grass is the latter end of August, and it is best to sow it in a mild day, when there is a likelihood of rain. When grass is sown in gardens, for lawns or walks, the seed of the best pasture-grass should be mingled with a good quantity of the white trefoil or Dutch clover, which will make a finer turf, and continue a better verdure than any other grass. When it is come up to any height it must be mowed, and this repeated very frequently, for the oftener it is mowed the thicker it grows. It should be rolled also frequently with a wooden roller. In autumn, wherever there are naked patches, the ground should be sown with fresh seed. Miller.

GRASS-bearing, in our Customs, *trading*, or turning up the earth with a plough. Hence the customary service for the inferior tenants of the manor of Amerden in Oxfordshire, to bring their ploughs to do one day's work for their lord, was called *grass-bearing* or *grass-burn*.

GRASSA, a name given by some authors to native *laras*.

GRASSETTE, in Botany, the name given by the French to the *pinguicula* or butter-wort, called also in Yorkshire *SANICLE*.

GRASSHOPPER, a species of ORTHOPTER. See LOCUST.

GRATICULATION, a term some writers use for the dividing a draught or design into squares, in order to the reducing it thereby.

GRATINGS, in a Ship, are small ledges of sawed plank, framed one into another like a lattice or prison grate, lying on the upper deck, between the main-mast and fore-mast, serving for a defence in a close fight, and also for the coolness, light, and convenience of the ship's company.

GRATIOLA, in Botany. See *HEDGE-HYSSOP*.

GRATITUDE, in Ethics, a virtue disposing the mind to an inward sense and outward acknowledgement of benefits received.

GRAVE, in Grammar, a species of accent opposite to acute. The grave accent is expressed thus, (`) and shews, that the voice is to be depressed, and the syllable over which it is placed, pronounced in a low, deep tone. GRAVE, in Music, is applied to a sound which is in a low or deep tone.

The thicker the chord or string, the more grave the tone or note, and the smaller the accent.

Notes are supposed to be the more grave, in proportion to the vibrations of the chord are less quick. See GAVITY, in Music.

GRAVE, in the Italian *Mythology*, serves to denote the slowest movement. See TIME.

GRAVE is also an ingredient in the composition of divers

terms in history and policy. Thus we say LAND-grave, BURG-grave, MARG-grave, FALL-grave, &c. The word, in this sense, is formed of the German *graf*, signifying *count*; called in the barbarous Latin *gravis* and *graphia*.

GRAVE is also used for a tomb, wherein a person deceased is interred.

GRAVEDO, a heaviness or listlessness which accompanies a lessened transpiration or taking cold, as it is commonly called. Hence, also, the case being frequently accompanied with a running of the nose and eyes, *gravedo* and *CORYZA* are sometimes used promiscuously. See CATARRH.

The signs of a *gravedo* are a distention and heaviness of the head, attended with sensitive and pressing pains, which sometimes become violently pungent, and, as it were, burning, a remarkable torquency of the vessels, thirst, and a dryness of the mouth, and undisturbed sleep; and finally, the breath is drawn into contents, and is attended with a sensitive and oppressive pain.

The *gravedo* is a species, or rather symptom, of the HEAD-ACID, and consequently is removed by the same means.

GRAVEL, in Natural History, coarser sand, found at the bottom and the sides of rivers.

The word is formed of the French *gravier*, which DuCange derives from the barbarous Latin *gratium*, signifying the same.

Mont. Perrault and Dr. Woodward lay down the difference between sand and gravel. The first is small, and consists of finer even grains; the latter is bigger, and consists of little pebbles and flints of various kinds, and mixed with the sand and the finer fragments of other stones.

Gravel is chiefly used in laying yards, courts, and walks, in gardens.

The gravel of England as much excels that of France, Holland, Flanders, &c. as the grass does. This and grass are the natural ornaments of a country-seat. We have several sorts of gravel in the different parts of England, but that which is common on Black-beach is the most valuable sort for garden-walks, as it consists of round, even, and beautiful pebbles, and when mixed with a stiff loam, binds well, and keeps in order the longest of all kinds of gravel.

GRAVEL-kind, in Botany. See CONVULVULUS.

GRAVEL-walks. These are deservedly esteemed a great advantage, which our gardens have over those of all other nations. The method of laying such walks is this:

The bottom should be laid with lime rubbish, or large flint stones, or any other hard matter, for eight or ten inches thick, to keep weeds from growing through, and over this the gravel is to be laid about six or eight inches thick: this should be laid rounding up in the middle, by which means the larger stones will run off to the sides, and may be raked away, for the gravel should never be screened before it is used. The most proper time for laying gravel is the month of March, and they should also be turned at this time, and not laid up in ridges in December, which is a frequent but injurious practice. It is a common mistake to lay these walks too round, which not only makes them more uneasy to walk on, but takes off from their apparent breadth. One inch in five feet is a sufficient proportion for the rise in the middle, so that a walk of twenty feet wide should be four inches higher in the middle than at the edges, and so in proportion. As soon as the gravel is laid it should be raked, and the large stones thrown back again; then the whole should be rolled both lengthwise and crosswise, and the person who draws the roller should wear shoes with flat heels, that he may make no holes, because holes made in a new walk are not easily remedied. The walks should always be rolled three or four times in very hard frosts, after which they will bind more firmly than they could ever be made otherwise to do.

In making gravel-walks, regard should be paid to the level of the ground, so that they may be laid with easy descents to the lower parts, in order to drain off the moisture; and where there are no declivities, it will be proper to have sink-stones laid, at convenient distances, by the sides of the walks: in dry ground, the water may be conveyed from hence into cisterns, and thus sink away; but in wet land, there should be underground drains, for conveying the water to the nearest pond or ditch.

Gravel, with some loam among it, binds much more firmly than the rarer kinds, and when gravel is naturally very hard and sharp, it is very proper to add a mixture of loam to it. The best gravel for walks is such as abounds with smooth round pebbles, which being mixed with a little loam, binds so firmly, as never to be injured after, either by wet or dry weather. These are not so

liable to be turned up by the feet in walking, as the more irregular-shaped pebbles, and remain much more firmly in their places after rolling. Millers.

Note, the flies next the body should be laid a foot and a half thick, or two feet, with turf, from whence the heat of the sun cannot be reflected as it is from *grass*, to the prejudice of the neighbouring flowers.

GRAVEL, in *Medicine*, a disease of the bladder and kidneys, occasioned by a sandy or gritty matter gathered therein, which cohering into a stony mass, prevents the due secretion and excretion of the urine.

The *gravel* is generally considered as the same disease with the calculus or stone.

The causes and symptoms of the *gravel* and stone are much the same, and they require a similar treatment, both with regard to regimen and medicine. See *STONE*.

GRAVELLING, among *Farriers*, a distorder incident to travelling horses, occasioned by little gravel-stones getting in between the hoof and the shoe, which, settling to the quick, fret and fester the part.

It is cured by pulling off the shoe, drawing the place to the quick, picking out all the gravel, and stopping up the foot with horse-grease and turpentine poured in hot.

GRAVELLY, *See* *SOIL*.

GRAVER, a steel instrument, serving to engrave on metals.

The *graver* consists of four files or faces, and the point usually terminates in a lozenge: in some it is round, and in others square. The round point is best for forcing lines, the square for cutting broad and deep, and the lozenge for more delicate and fine strokes and scratches. Le Boile recommends that of a form betwixt the square and lozenge. See *ENGRAVING*.

The *graver* should be made of the best steel, which must be drawn out into small rods with a charcoal fire. These rods, after having been cut into the proper lengths for *gravers*, should be softened, by heating them in a charcoal fire, and suffering them to cool very slowly: let them next be filed into the desired form, and brought back to a hard temper by heating them red-hot, and in this state dipping their ends into soft soap. This should be done in a perpendicular direction; for, if they be turned in the least degree obliquely, the *graver* will warp and be crooked. If the temper of the *graver* be too hard after this treatment, and prevent the whetting it properly to an edge, it may be softened, by laying its end on a large burning piece of charcoal till it begins to grow yellow, and then thrusting it into a lump of tallow, or dipping it in water; but if water be used, the *graver* must not be too hot. It may be known whether the *graver* be tempered to a proper hardness by touching the edge of it with a file, which, if any effect attends it, proves the temper to be too soft. The best proof of too great hardness is the breaking of the point in engraving; after which, if a new edge be made by whetting the *graver*, it will be frequently found very good without any other alteration. Handmaid to the Arts, vol. ii. p. 66.

The other end is fitted into a wooden handle. Besides engravers, the seal-cutters, locksmiths, gunsmiths, goldsmiths, armourers, spurrers, &c. likewise make use of *gravers*.

GRAVING, the art or art of cutting lines, figures, and other designs, on metals: more properly called *ENGRAVING*.

GRAVINGS, in the *Sea-Langage*, is the bringing a ship aground, and then boring off with surze, reed, or broom, all the filth and foulness that sticks to her bottom without board, in order to pay her anew. See *BROOMING* and *CAREENING*.

GRAVITAS, *Externa*, in the *Ancient Music*, was used to signify a sound produced by the remission or falling of the voice. *Gravitas* differs from remission, as the effect from the cause.

GRAVITAS is also used to denote the state of a woman going with child. See *PREGNANCY*.

GRAVITATION, the exercise of gravity, or the pressure a body exerts on another body underneath it by the power of gravity.

It is sometimes distinguished from gravity. Thus Monsieur Maupertuis takes gravity for that force whereby a body would fall to the earth if supported at rest; and *gravitation* for the same, but diminished by the centrifugal force. See *Virg. of the Earth* determin'd. of Mr. Murdoch's translation.

It is only *gravitation*, or gravity thus blended with the centrifugal force, that we can measure by our experiments. However, methods have been found to distinguish what remains of primitive gravity, and what has been destroyed by the centrifugal force.

It is one of the laws of nature, discovered by Sir Isaac Newton, and now received by most philosophers, that every particle of matter in nature gravitates towards every

other particle; which law is the hinge whereon the whole *NEWTONIAN philosophy* turns.

What we call *gravitation*, with respect to the gravitating body, is properly called *attraction* with respect to the body gravitated to.

The planets, both primary and secondary, as also the comets, do all gravitate towards the sun, and toward each other; and the sun toward them; and that in proportion to the quantity of matter in each.

The Peripatetics, &c. held, that bodies only gravitate when out of their natural places, and that *gravitation* ceases when they are restored to the same, the intention of nature being then fulfilled. The final cause of this faculty, they held, is only to bring elementary bodies to their proper place, where they may rest. But the moderns say, that bodies exercise gravity even when at rest, and in their proper places.

This is particularly shown of fluids; and it is one of the laws of hydrostatics, demonstrated by Mr. Boyle and others, that fluids gravitate in *proportion* to the upper parts pressing on the lower, &c.

For the laws of *gravitation* of bodies in fluids specifically lighter or heavier than themselves, see *SPECIFIC GRAVITY*, &c.

GRAVITATION, centre of. See *CENTRE*.

GRAVITATION, line of. See *LINE*.

GRAVITATION, plane of. See *PLANE*.

GRAVITY, in *Physics*, the natural tendency or inclination of bodies towards the centre.

In this sense gravity coincides with *CENTRIFUGAL FORCE*. Gravity is defined by others, more generally, to be the natural tendency of one body towards another; and by others more generally still, the mutual tendency of each body, and each particle of a body, towards all others: in which sense the word coincides with what we more usually call *ATTRACTION*.

The terms *gravity*, *centrifugal force*, weight, and *attraction*, do, in effect, all denote the same thing, only in different views and relations; which disconcert relations, however, authors are apt to confound, and, accordingly, the four are frequently used promiscuously.

In propriety, when we consider a body as tending towards the earth, the force wherewith it tends we call *gravity*, *force of gravity*, or *gravitating force*; the same force, when we consider it as immediately tending to the centre of the earth, we call *centrifugal force*; the same, when we consider the earth, or body to which it tends, we call *attraction* or *attractive force*; and when we consider it, in respect of an oblique course a body is in the way of its tendency, upon which it acts, we call it *weight*. Philosophers conceive very differently of *gravity*: its nature, use, phenomena, causes, effects, and extent, have afforded various speculations in all ages.

Some consider it as an *active* property or *innate* in bodies, whereby they endeavour to join their centre. Others hold *gravity* in this sense to be an occult quality, and, as such, to be exploded out of all sound philosophy. Sir Isaac Newton, though he frequently calls it a *vis*, power, or property in bodies, yet explains himself, that all he intains by the word is the effect or the phenomenon. He does not consider the principle, the cause whereby bodies tend downwards, but the tendency itself, which is an occult quality, but a sensible phenomenon, by its causes what they will, whether a property essential to body, in some make it, or superadded to it, as others; or even an impulse of some body from without, as others.

It is a law of nature long observed, that all bodies near the earth have a *gravity*, or a tendency towards the centre of the earth; which law the moderns, and particularly the immortal Sir Isaac Newton, have found, from certain observations, to be much more extensive, and to hold universally with respect to all known bodies in nature.

It is now, therefore, acknowledged a principle or law of nature, that all bodies, and all the particles of all bodies, *gravitate* towards each other mutually, from which single principle Sir Isaac Newton has happily deduced all the great phenomena of nature. See *NEWTONIAN philosophy*.

Hence *gravity* may be distinguished into *particular* and *general*.

GRAVITY, *particular*, is that whereby heavy bodies descend towards the centre of the earth.

GRAVITY, *general*, or *universal GRAVITY*, is that whereby all circumstantial bodies do, heavily tend towards a point, which is either accurately or very nearly the centre of magnitude of the terrestrial globe; not as if there was really any virtue or charm in the point called the centre, by which it attracted bodies; but because this is the result of the gravitation of bodies towards all the parts of which the earth consists.

2. This point or centre is fixed within the earth, or, at least, hath been so ever since we have had any authentic history: for a consequence of its lasting, though ever so little, would be the overflowing of the low lands, on that side of the globe towards which it approached. Dr. Halley suggests, it would well account for the universal deluge, to have the centre of gravitation removed for a time towards the middle of the then inhabited world; for the change of place, but the twentieth part of the radius of our earth, would be sufficient to lay the tops of the highest hills under water. See DISTANCE.

3. In all places which are equidistant from the centre of the earth, the force of gravity is nearly equal. Indeed, all places of the earth's surface are not at equal distances from the centre, because the equatorial parts are something higher than the polar parts; the difference between the earth's diameter and axis being about thirty-four English miles, which hath been proved by the necessity of making the pendulum shorter in those places, before it will swing seconds. See FIGURE of the EARTH.

4. Gravity equally affects all bodies, without regard either to their bulk, figure, or matter: so that, abstracting from the resistance of the medium, the most compact and loose, the greatest and smallest bodies would descend equal spaces in equal times, as appears from the quick descent of very light bodies in an exhausted receiver. Hence, a very great difference may be observed between gravity and magnetism; the latter affecting only iron, and that towards its poles; the former all bodies alike, and that in every part.

Hence it follows, that gravity, in all bodies, is proportionable to their quantity of matter; so that all bodies consist of matter equally heavy.

Hence also may be concluded, that there is no such thing as pulvill levity: those things which appear light being only comparatively so.

If several things ascend and swim in fluids, it is only because they are not, bulk for bulk, so heavy as those fluids; nor is there any reason why cork, for instance, should be said to be light, because it swims in water, any more than iron, because it will swim on mercury.

5. This power increases as we descend to, and decreases as we ascend from the surface of the earth, and that in the proportion of the squares of the distances from the centre reciprocally: so as, for instance, at a double distance, to have but a quarter of the force, &c. Thus, a body, which, on the earth's surface, or at the distance of one semi-diameter from the centre, weighs 3600, will, at the distance of two, three, four, &c. semi-diameters, weigh 900, 400, 225, &c. pounds respectively. But this power decreases below the surface of the earth in the simple proportion of the distances from the centre.

This proposition may be expressed more generally thus: the weights of the same bodies, at different distances from the centre of the earth, above the surface, are reciprocally as the squares of the distances; and below the surface, directly as the distances from the centre: and therefore, at the surface, their gravity is the greatest.

6. As all bodies gravitate towards the earth, so does the earth equally gravitate towards all bodies, i.e. the action of gravity is mutual on each side, and equal. See REACTION.

Hence also the attractive powers of bodies, at equal distances from the centre, are as the quantities of matter in the bodies.

Hence also it appears, that the attractive force of the entire bodies consists of the attractive forces of the parts; for, by the adding or taking away any part of the matter of a body, its gravity is increased or diminished in the proportion of the quantity of such particle to the entire mass.

GRAVITY, general or universal. The existence of the same principle of gravity in the superior regions of the heavens, as well as on earth, is easily proved.

That all motion is naturally rectilinear is allowed by all: those bodies, therefore, which move in curves, must be retained therein by some power continually acting on them.

Hence, the planets being found to revolve in curvilinear orbits, we infer that there is some power, by whose constant influence they are prevented from flying off in tangents.

Again, it is proved by mathematicians, that all bodies moving in any curve line described in a plane, and which, by radii drawn to any certain point, describe areas about the point proportionable to the times, are impelled, or acted on, by some power tending towards that point: now it is shown by the astronomers, that the primary planets round the sun, and the secondary planets round the primary ones, do describe areas proportionable to the times. Consequently the power whereby they are re-

tained in their orbits, is directed towards the bodies placed in the centres thereof.

Lastly, it is demonstrated, that if several bodies revolve with an equable motion in several concentric circles, and the squares of their periodical times be as the cubes of the distances from the common centre, the centripetal forces of the revolving bodies will be reciprocally as the squares of the distances. Or, if bodies revolve in orbits approaching to circles, and the apses of those orbits be at rest, the centripetal forces of the revolving bodies will be reciprocally as the squares of the distances.

Now, the astronomers all agree, that both these cases obtain in all the PLANETS: whence it follows, that the centripetal powers of all the planets are reciprocally as the squares of the distances from the centres of the orbits.

Upon the whole, it appears, that the planets are retained in their orbits by some power which is continually acting on them: that this power is directed towards the centres of their orbits: that the intensity or efficacy of this power increases upon an approach towards the centre, and diminishes as it recedes from the same; and that it increases in the same proportion as the distance diminishes: and diminishes in the same as the distance increases. Now by comparing this centripetal force of the planets with the force of gravity on earth, they will be found perfectly alike.

This we shall illustrate in the case of the moon, the nearest to us of all the planets. The rectilinear forces described in any given time by a falling body, urged by any powers, reckoning from the beginning of its descent, are proportionable to those powers. Consequently the centripetal force of the moon revolving in its orbit, will be to the force of gravity on the surface of the earth, as the space which the moon would describe in falling, any little time, by her centripetal force towards the earth, if she had no circular motion at all, to the space a body near the earth would describe in falling, by its gravity towards the same.

Now, by a natural calculus of those two spaces, it appears, that the first of them is to the second, i.e. the centripetal force of the moon revolving in her orbit, is to the force of gravity on the surface of the earth, as the square of the earth's semidiameter to the square of the semidiameter of her orbit: which is the same ratio as that of the moon's centripetal force in her orbit, to the same force near the surface of the earth.

The moon's centripetal force, therefore, is equal to the force of gravity. These forces, consequently, are not different, but they are one and the same: for, were they different, bodies acted on by the two powers conjointly, would fall towards the earth, with a velocity double to that arising from the sole power of gravity.

It is evident, therefore, that the moon's centripetal force, whereby she is retained in her orbit, and prevented from running off in tangents, is the very power of gravity of the earth, extended thither.

This reasoning may be further illustrated and confirmed in the following manner: let RAE, Tab. III. *Astronomy*, fig. 78, represent the earth, T its centre, VL the orbit of the moon, and LC a part of it described by the

moon in a minute, which is equal to $\frac{1}{39343}$ of the whole

periphery, or 33 seconds of a degree; because the moon completes her whole course in 27 days, 7 hours, 43 minutes, or in 39343 minutes. Moreover, the circumference of the earth, according to M. PIGAN's mensuration, is 123249600 Paris feet, and therefore its semidiameter TA = 19614800 feet; and TL, the semidiameter of the moon's orbit, will be 117661800 feet, or = 60 times TA; and the versed sine LD of the arc LC = 33", computed by means of tables, or LC, will be 15,7 feet, nearly; or, LD may be found without tables thus: the whole circumference of the moon's orbit, or 60×123249600 , is equal to 7394976000, which, divided by 39343, will give the arc LC = 17661 feet: but by a well known theorem in geometry, supposing the arc LC, which is a very small part of the moon's orbit,

to be rectilinear, $LC^2 = LD \times 1LT$, i.e. $LD = \frac{LC^2}{1LT}$ or the square of 187661, which is 3529337521, divided by 2353896000, will give 15,013.

Note, a distance of the moon somewhat greater than 60 times the diameter of the earth would afford a more exact result; and the force whereby the moon is restrained in its orbit should also be increased in the proportion of 19752 to 17832, in order to have the exact centripetal force of the moon, such as it would be undiminished by the action of the sun, and with this correction the above number 15,013, &c. will become 15,097, &c. or 15

15 $\frac{1}{2}$ very nearly. See Newton's Princip. lib. I. Prop. 43. cor. 2. and lib. III. prop. 3. In either way of calculation it appears that the force, whereby the moon is drawn off from the tangent L.B. or retained in its orbit, impels it towards the centre of the earth about 15 $\frac{1}{2}$ Paris feet in one minute: but this force, being known from the elliptic figure of her orbit to be reciprocally proportional to the square of the distance, would impel the moon, if suppos'd to be at the surface of the earth, through a space equal to $60 \times 60 \times 15\frac{1}{2}$ feet in one minute. But bodies, impelled by the force of gravity, fall near the surface of the earth through the space of 15 $\frac{1}{2}$ Paris feet in one second, and the spaces being as the squares of the times, through $60 \times 60 \times 15\frac{1}{2}$ in a minute. Wherefore as the force, by which the moon is retained in its orbit, and the force of gravity produce the same effects in the same circumstances, and tend towards the same point, they are the same forces.

The moon, therefore, gravitates towards the earth; and the earth reciprocally towards the moon: which is farther confirmed by the phenomena of the TIDES.

The like reasoning might be applied to the other planets. For, as the revolutions of the primary planets round the sun, and those of the satellites of Jupiter and Saturn round their primaries are phenomena of the same kind as the revolution of the moon round the earth; as the centripetal powers of the primary are directed towards the centre of the sun, and those of the satellites towards the centres of their primaries; and, lastly, as all these powers are reciprocally as the squares of the distances from the centres; it may safely be concluded, that the power and cause are the same in all.

Therefore, as the moon gravitates towards the earth, and the earth towards the moon, to do all the secondaries to their primary ones; the primaries to their secondary ones; so, also, do the primary ones to the sun, and the sun to the primary ones. Newton's Princip. lib. III. prop. 4. 5. 6. Greg. Alibi lib. I. sect. 7. prop. 46 and 47.

GRAVITY, phenomena, or properties, of universal. 1. All the several particles of all bodies in nature gravitate to all the particles of all other bodies.

To what has been urged in proof heretofore, from the analogy between the motions of the several bodies in our system, it may be added, that Saturn is actually observed by astronomers to change its course when nearest to Jupiter; and Jupiter, also, is found to disturb the motion of the satellites of Saturn. So that the gravitation of those bodies is matter of actual observation.

2. The quantity of this gravity, at equal distances, is always proportional to the quantity of matter in the gravitating bodies. For the powers of gravity are as the quantities of motion they generate; which quantities in unequal bodies, equally swift, are in each other as the quantities of matter. Consequently, since unequal bodies, which are equally swift, are to each other as the quantities of matter; therefore, since unequal bodies at the same distance from the attracting body are found to move equally swift, by gravity, it is evident, the forces of gravity are proportional to the quantities of matter.

3. The proportion of the increase, or decrease, of gravity in the approach, or removal of bodies from each other, is this; that the force is reciprocally in a duplicate ratio, i. e. it is as the square of the distance. Thus, suppose a body of an hundred pounds, at the distance of ten diameters from the earth; the same body, if its distance were but half so great, would have quadruple the weight: if its distance were but one-third of the former, its weight would be nine times as great, &c. Hence we deduce the following corollaries: 1. That at equal distances from the centres of homogeneous bodies, the gravity is directly as the quantity of matter, and inversely as the square of the diameter. 2. That on the surfaces of equal spherical, and homogeneous bodies, the gravities are as the densities. 3. That on the surfaces of spherical, homogeneous, equally dense, but unequal bodies, the gravities are inversely as the squares of the diameters. 4. That if both the densities and diameters differ, the gravities on the surfaces will be in a ratio compounded of the densities and the diameters.

Lastly, that a body placed any where, within a hollow sphere, which is homogeneous, and every where of the same thickness, will have gravity whosoever it be placed, the opposite gravities always precisely destroy each other. For the particular laws of the descent of bodies, by the force of gravity, see DESCENT of Bodies, and CENTRIFUGAL Force.

GRAVITY, cause of. We have various theories advanced by the philosophers of various ages to account for this grand principle of gravitation. The ancients, who were only acquainted with particular gravity, or the tendency of sublunar bodies towards the earth, aimed no farther than at a system which might answer the more obvious

phenomena of the same; but the moderns, as their principle is higher, and more extensive, to shroud their theory be.

However, we find some hints concerning the gravitation of celestial bodies in the account transmitted to us of the doctrines of Thales and his successors; but Pythagoras seems to have been better acquainted with it, and is supposed to have had a view to it, in what he taught concerning the HARMONY of the spheres.

Aristotle, and the Peripatetics, content themselves to refer gravity or weight to a native inclination in heavy bodies to be in their proper place or sphere, the centre of the earth.

Copernicus ascribes it to an innate principle in all parts of matter, whereby, when separated from their wholes, they endeavour to return to them again the nearest way.

In answer to Aristotle and his followers, who considered the centre of the earth as the centre of the universe, he observed, that it was reasonable to think there was nothing peculiar to the earth in this principle of gravity; that the parts of the sun, moon, and stars tended likewise to each other, and that their spherical figure was preferred in their various motions by this power. Copern. Revol. lib. I. cap. 9.

But neither of these systems assigns any physical cause of this great effect: they only amount to this, that bodies descend, because they are inclined to descend.

Kepler, in his preface to the commentaries concerning the planet Mars, speaks of gravity as of a power that was mutual betwixt bodies, and tells us, that the earth and moon tend towards each other, and would meet in a point to many times nearer to the earth than to the moon, as the earth is greater than the moon, if their motions did not hinder it. He adds, that the TIDES arise from the gravity of the waters towards the moon. To him we also owe the important discovery of the analogy between the distances of the several planets from the sun, and the periods in which they complete their revolutions: viz. that the squares of their periodic times are always in the same proportion as the cubes of their mean distances from the sun. Nevertheless, Kepler, Gassendus, Gilbert, and others, ascribe gravity to a certain magnetic attraction of the earth. These authors conceive the earth to be one great magnet continually emitting effluvia, which lay hold on all bodies, and draw them toward the earth. But this, we have observed, is inconsistent with the several phenomena.

Descartes, and his followers, Rohault, &c. attribute gravity to an external impulse, or trifling of some subtle matter. By the rotation of the earth, say they, all the parts and appendages thereof necessarily endeavour to recede from the centre of rotation: but they cannot, all, actually recede, as there is no vacuum or space to receive them.

If now we suppose the earth ABCD, Tab. Mechan. fig. 8. and L a terrestrial body placed in the pyramidal space, AEB; it follows that the matter in this pyramid will have so much less endeavour to recede from the centre, as the body L has a less endeavour than the fluid matter whose place it possesses. Hence it will follow, that the matter of adjacent pyramids receding with more force; that in the pyramid AEB, and particularly the body L, will be thereby driven toward the centre for the same reasons as cork, though a heavy body, ascends in water. This hypothesis, though ingenious enough, yet, as it is founded on the supposition of a plenum, is overthrown by what has been since proved of the existence of a vacuum. See CARTESIAN Philosophy.

Dr. Hook inclines to an opinion much like that of Descartes: gravity he thinks deducible from the action of a most subtle medium, which easily pervades and penetrates the most solid bodies; and which, by some motion it has, detaches all earthly bodies from it, towards the centre of the earth.

Vossius, and many others, give partly into the Cartesian notion, and suppose gravity to arise from the diurnal rotation of the earth round its axis.

Dr. Halley, despairing of any satisfactory theory, chooses to have immediate recourse to the agency of the Almighty. So Dr. Clarke, from a view of several properties of gravity, concludes that it is no adventitious effect of any motion, or subtil matter, but an original and general law impressed by the Almighty on all matter, and preferred therein by some efficient power penetrating the very solid and intimate substance thereof; as being found always proportionable, not to the surfaces of bodies or corporeities, but to their fluid quantity and contents. It should, therefore, be no more inquired, why bodies gravitate, than how they came to be first put in motion. ANTON. in Rohault. Phys. parti. cap. xi. sect. 16.

of their absolute *gravities* directly, and their *specific gravities* inversely.

VII. A body *specifically* heavier than a fluid, loses so much of its weight therein, as is equal to the weight of a quantity of the fluid of the same bulk.

For, suppose a cubic inch of lead immersed in water; a cubic inch of water will, thereby, be expelled from its place; but the weight of this water was sustained by the resistance of the ambient water. Therefore, such a part of the weight of the leaden cube, must be sustained by the resistance of the ambient water, as is equal to the weight of the water expelled. The *gravity* of the body immersed, therefore, must be diminished by so much.

Hence, 1. Since a fluid *specifically* heavier, has a greater weight in the same bulk, than a lighter; the same body will lose a greater part of its weight in a fluid, *specifically* heavier, than in a lighter; and therefore it weighs more in a lighter than a heavier.

2. Equal homogeneous bodies weighing equally in air, lose their equilibrium if one of them be immersed in a heavier fluid; the other in a lighter.

3. Since the *specific gravities* are as the absolute *gravities* under the same bulk; the *specific gravity* of the fluid, will be to the *gravity* of the body immersed, as part of the weight lost by the fluid, to the whole weight.

4. Two solids equal in bulk, lose the same weight in the same fluid; but the weight of the *specifically* heavier body is greater than that of the *specifically* lighter; therefore, the *specifically* lighter loses a greater part of its weight than the *specifically* heavier.

5. Since the bulks of bodies equal in weight, are reciprocally as the *specific gravities*; the *specifically* lighter loses more weight in the same fluid than the heavier; wherefore, if they be in equilibrium in one fluid, they will not be so in another; but the *specifically* heavier, will preponderate, and that the more, as the fluid is denser.

6. The *specific gravities* of fluids, are as the weights lost by the same fluid immersed in the same.

VIII. To find the *specific gravity* of a fluid. On one arm of a balance suspend a leaden globe; and to the other, fillen a weight, which is an equilibrium therewith in the air. Immerse the globe successively in the several fluids, whose *specific gravities* are to be determined, and observe the weight which balances it in each. These several weights, subtracted, severally, from the first weight, the remainders are the parts of the weight lost in each fluid. Whence the ratio of the *specific gravity* of the fluids is seen.

Hence, as the densities are as the *specific gravities*; we find the ratio of the densities of the fluids at the same time.

This problem is of the utmost use; as by it the degree of purity or goodness of fluids is easily found; a thing not only of service in natural philosophy, but also in common life, and in the practice of physic. See HYDROMETER.

That the *specific gravity* may be found the more accurately, the weight of the thread not immersed in the fluid is to be subtracted from the weight of the solid in air; and the force necessary to make the thread subside (if it be *specifically* lighter) is to be added to the weight lost. But if the thread that sustains the solid be heavier than the fluid; the weight of the thread in the air is to be subtracted from the weight of the solid in air; and the weight the thread loses from the weight lost in the fluid. Indeed, this precaution may be spared, if in examining the *specific gravity* of several fluids, care be taken that the same thread be immersed to the same depth in each.

IX. To determine the ratio which the *specific gravity* of a fluid has to the *specific gravity* of a solid that is *specifically* heavier than the fluid.

Weigh any mass of the solid in a fluid, and note the full weight therein; the *specific gravity* of the fluid will be to that of the solid, as the part of the weight lost by the solid to its whole weight.

X. The *specific gravity* of equally heavy bodies, are reciprocally as the quantities of weight lost in the same fluid. Hence we find the ratio of the *specific gravities* of solids, by weighing masses thereof, that are equal in air, in the same fluid; and noting the weights lost by each.

The *specific gravities* of various solids, have been determined by many authors. Marin Ghetaldus particularly, tried the *specific gravities* various bodies had, especially metallic ones; which were borrowed thence by Oughtred. In the Philosophical Transactions, we have ample tables of *specific gravities*, by various authors. See Vol. xlv. p. 335, &c. It will be sufficient for us to give those of some of the

more usual bodies, as determined with great care and accuracy by M. Petit; and published by F. Mercurius; and from him by several others.

TABLE of the *specific gravities* of several solids.

An hundred pound weight in gold is equal in bulk to	
714 of mercury	381 of fine tin
604 of lead	26 of leadstone
543 of silver	31 of marble
472 of copper	14 of stone
45 of brass	124 of sulphur
42 of iron	5 of wax
39 of tin	54 of water

A TABLE of the *specific Gravities* of solid and fluid Bodies.

A cubic inch of	Troy weight.			Averdupois weight.		Comparative weight.
	oz.	p.w.	gr.	oz.	drams.	
Very fine gold	10	7	3.83	11	5.80	19.637
Standard gold	9	19	6.44	10	14.90	18.888
Guinea gold	9	7	17.18	10	4.70	17.793
Moidore gold	9	0	10.84	0	14.71	17.140
Pure quicksilver	7	7	11.61	8	14.51	16.919
Lead	5	10	27.35	6	9.08	11.325
Fine silver	5	10	23.23	6	6.66	11.085
Standard silver	5	11	3.30	6	1.54	10.335
Copper	4	13	7.04	5	1.89	8.843
Plate brass	4	4	9.60	4	10.20	8.000
Steel	4	2	20.12	4	8.70	7.312
Iron	4	0	15.20	4	6.77	7.645
Block tin	3	17	5.68	4	3.79	7.321
Spelter	3	14	11.88	4	1.42	7.065
Lead ore	3	11	17.76	3	14.90	6.800
Glass of antimony	2	15	10.89	3	0.89	5.280
German antimony	2	2	4.80	2	5.04	4.000
Copper ore	2	1	14.83	2	4.43	3.775
Diamond	1	15	20.88	1	15.48	3.400
Clear glass	1	13	5.58	1	13.16	3.150
Lapis lazuli	1	12	5.27	1	12.27	3.054
Wells asphalt	1	10	17.57	1	10.97	2.913
White marble	1	8	13.41	1	9.00	2.707
Black marble	1	8	13.03	1	9.02	2.704
Rock crystal	1	8	7.00	1	8.61	2.658
Green glass	1	7	15.38	1	8.26	2.610
Cornelian stone	1	7	1.21	1	7.73	2.568
Flint	1	6	19.63	1	7.53	2.542
Hard paving stone	1	5	24.87	1	6.77	2.460
Live sulphur	1	1	24.01	1	2.52	2.000
Nitre	1	0	1.08	1	1.59	1.000
Alabaster	0	19	18.74	1	1.35	1.875
Dry ivory	0	10	6.00	1	0.89	1.825
Brimstone	0	18	23.76	1	0.66	1.800
Alum	0	17	21.91	0	15.72	1.714
Ebony	0	11	15.82	0	10.34	1.117
Human blood	0	11	2.89	0	9.76	1.054
Amber	0	10	20.79	0	9.54	1.030
Cow's milk	0	10	20.79	0	9.54	1.030
Sea water	0	10	20.79	0	9.54	1.030
Pump water	0	10	13.30	0	9.10	1.000
Spring water	0	10	13.94	0	9.12	0.999
Distilled water	0	10	11.42	0	9.10	0.993
Red wine	0	10	11.42	0	9.10	0.993
Oil of amber	0	10	7.63	0	9.06	0.978
Proof spirits	0	9	16.73	0	8.62	0.931
Dry oak	0	9	18.00	0	8.58	0.925
Olive oil	0	9	15.17	0	8.45	0.913
Pure spirits	0	9	3.27	0	8.02	0.866
Spirits of turpentine	0	9	8.76	0	7.99	0.864
Oil of turpentine	0	8	8.53	0	7.33	0.772
Dry ash-tree	0	8	1.69	0	7.08	0.705
Alber	0	7	14.00	0	6.65	0.720
Sulphur wood	0	5	2.04	0	4.40	0.484
Cork	0	2	12.77	0	2.21	0.249

If you take away the decimal point from the numbers in the right hand column, or, which is the same, multiply them by 1000, they will show how many avoirdupois ounces are contained in a cubic foot of each body. If the magnitude of any body be multiplied by the *specific gravity* in the table, the product will be the avoirdupois weight, e. gr. let it be required what weight of lead

— of a foot thick will cover a building whose area is 100

3000 feet. Ans. $3000 \times \frac{1}{100} \text{ or } (300) \times 11.375 = 3397.500$ ounces, or about 947 tons, the weight required. Again, the *specific gravity* of any body, whose weight and bulk are known, may be found by dividing the weight by its magnitude: e. gr. let a piece of marble contain four cu-

bic feet, and weigh six hundred and three pounds, or to 800 ounces, then $\frac{10800}{4} = 2700$, its specific gravity as

in the table, nearly. Farther, the magnitude of a body, whose weight is known, may be found by dividing the weight by the specific gravity in the table. See HAZON'S CRESCENT.

To determine the specific gravity of bodies accurately, requires so much care, and is liable to so many difficulties, that we need not be surprised when we find authors differing from one another. Dr. Richard Davies, in the Philos. Transact. N° 488. has with great pains and judgment collected all the experiments of this kind, that have been made by the most accurate authors, shewing how widely they disagree, and pointing out the causes of their difference: and he has also given us the specific gravities of several substances from his own observations; to which we refer the curious. See also tables of the specific gravities of a great variety of metals, minerals, ores, stones, fossils, &c. animal, vegetable, and miscellaneous substances, and fluids, in Martin's Philosoph. Britan. vol. i. p. 290, &c. and Muschenbroeck. Introduct. ad Phil. Nat. tom. ii. p. 336, &c. edit. 1762.

At different seasons of the year, the specific gravities of the same fluids, are found different. This was first discovered by M. Houbert; and Jean, Bapt. Eisenchmidt, in his Disquisitio nova de Ponderibus, &c. gives us variety of experiments relating hereto: the principal whereof, to save the trouble of too frequent experiments, we shall here subjoin.

TABLE for the specific Gravities of several Fluids.

A cubic inch Paris measure.	In summer.	In winter.
oz. dr. gr.	oz. dr. gr.	oz. dr. gr.
Oil mercury	7 1 66	7 2 14
Oil of vitriol	7 59	7 71
Spirit of vitriol	5 33	5 38
Spirit of nitre	6 24	6 44
Spirit of salt	5 49	5 55
Aqua fortis	6 23	6 35
Vinegar	5 15	5 21
Distilled vinegar	5 11	5 15
Burgundy wine	4 67	4 75
Spirit of wine	4 37	4 43
Pale ale	5 1	5 9
Brown ale	5 2	5 7
Cow's milk	5 20	5 25
Goat's milk	5 24	5 28
Urine	5 14	5 19
Spirit of urine	5 45	5 53
Oil of tartar	7 27	7 43
Oil of olives	4 53	Is froze in winter
Oil of turpentine	4 39	4 46
Sea water	6 12	6 18
River water	5 10	5 13
Spring water	5 11	5 14
Distilled water	5 8	5 11

XI. A body specifically heavier, descends in a fluid specifically lighter, with a force equal to the excess of its weight, above that of an equal quantity of the fluid.

Hence, 1. The force which sustains a specifically heavier body in a fluid, is equal to the excess of the absolute gravity of the body, above that of the fluid, under the same bulk: e. gr. 473 pound of copper loses 51 pounds of its weight in water; therefore a power of 423 pounds is able to sustain it.

2. Since the excess of the weight of a solid over the weight of a fluid specifically heavier, is less than that over the weight of a specifically lighter fluid under the same bulk; it will descend with less force in a specifically heavier fluid than in a lighter; and consequently, it will descend more slowly in the former than in the latter.

XII. A specifically lighter body, sinks in a heavier fluid, till the weight of a quantity of the fluid, equal in bulk to the part immersed, be equal to the weight of the whole body.

Hence, 1. Since the specific gravities of bodies of the same weight, are reciprocally as their bulks; and the bulks of fluids equal in weight, are as the parts of the same solid immersed therein; the specific gravities of fluids are reciprocally as the parts of the same body immersed therein.

2. A solid, therefore, immerses deeper in a lighter fluid than in a heavier, and deeper, as the proportion of the specific gravity of the solid to that of the fluid is greater.

3. If a body be of the same specific gravity with a fluid;

the whole body will be immersed; and it will remain in any given place of the fluid.

4. If a specifically lighter body be wholly immersed in a fluid, it will be urged by the collateral column of the fluid, to ascend with a force equal to the excess of the weight of the fluid, bulk for bulk, over the weight of the solid.

5. A body, therefore, specifically lighter, lying on the bottom of a vessel, will not be raised up, unless the heavier fluid rise above such a part, as is equal in bulk to a quantity of the fluid of the same weight with the whole solid, XIII. The specific gravity of a solid is to the specific gravity of a lighter fluid, wherein it is immersed, as the bulk of the part immersed, is to the whole bulk.

XIV. The specific gravities of equal solids, are as their parts immersed in the same fluid.

XV. The weight and bulk of a specifically lighter body, and the weight of the specifically heavier fluid, being given, to find the force required, to keep the solid wholly immersed under the fluid.

As this force is equal to the excess of the weight of the fluid beyond that of an equal bulk of the solid; from the given bulk of the solid, and the weight of a cubic foot of water, find, by the rule of three, the weight of a bulk of water equal to that of the body. From this subtract the weight of the solid; the remainder is the force required.

E. gr. Suppose the force necessary to detain a solid eight feet in bulk, and 100 pounds in weight, under water, required: since a cubic foot of water is found to weigh 70 pounds, the weight of water under the bulk of eight feet, is 560; whence, 100 pounds, the weight of the solid, being subtracted, the remainder 460 pound, is the force necessary to detain the solid under water.

Hence, since a specifically lighter body ascends in a heavier fluid, with the same force that would prevent its ascent; by the present problem, we can likewise find the force wherewith a specifically lighter body ascends in a heavier.

XVI. The weight of a vessel, to be made of a specifically heavier matter; and that of a specifically lighter fluid, being given; to determine the cavity the vessel must have, to swim on the fluid.

The weight of a cubic foot of the fluid being given; the bulk of the fluid equal to the weight of the vessel, is found by the rule of three. If, then, the cavity be made a little bigger than this, the vessel will have less weight under the same bulk, than the fluid, and will therefore be specifically lighter than the same, and consequently, it will swim.

XVII. The force employed to retain a specifically lighter solid, under a heavier fluid; and the weight lost by a heavier solid in a lighter fluid, are each added to the weight of the fluid, and weigh together with it.

The several theorems here delivered, are not only all demonstrable from the principles of mechanics; but are conformable to experiment. In effect, experience is here found to answer exactly to calculation, as is abundantly evident from the courses of philosophical experiments, now frequently exhibited; where the laws of specific gravitation are well illustrated. See HYDROSTATICAL balance.

GRAVITY of the air. See WEIGHT of the air, AIR, and ATMOSPHERE.

SPECIFIC GRAVITY of living men. See SPECIFIC GRAVITY.

GRAVITY, in Music, is an affection of sound, whereby it becomes denominated grave, low, or flat.

Gravity stands in opposition to ascensiveness, which is that affection of sound, whereby it is denominated acute, sharp, or high.

The relation of gravity and acuteness is the principal thing concerned in music, the distinctness, and determinateness of which relation give found the denomination of harmonical, or musical.

The degrees of gravity, &c. depend on the nature of the sonorous body itself, and the particular figure and quantity thereof: though, in some cases, they likewise depend on the part of the body where it is struck. Thus, e. gr. the sounds of two bells of different metals, and the same shape and dimensions, being struck in the same place, will differ as to acuteness and gravity; and two bells of the same metal will differ in acuteness, if they differ in shape or magnitude, or be struck in different parts.

So in chords, all other things being equal, if they differ either in matter, or dimensions, or tension, they will also differ in gravity.

Thus again, the sound of a piece of gold is much graver than that of a piece of silver of the same shape and dimensions; and in this case, the tones are, *cavities paribus*, proportional to the specific gravities: so a solid sphere of brass, two feet in diameter, will sound graver than another of one foot diameter; and here the tones are proportional to the quantities of matter, or the absolute weights.

But

But it must be observed, that acuteness and gravity, as also loudness and lowness, are but relative things. We commonly call a sound acute and loud, in respect to another which is grave, or low with respect to the former; so that the same found may be both grave and acute, and also loud and low, in different comparisons.

The degrees of acuteness and gravity, make the different tones, or runs, of voice, or found; so we say one found is in tune with another, when they are in the same degree of gravity.

The immediate cause or means of this diversity of tones lies very deep. The modern musicians fix it on the different velocity of the vibrations of the sonorous body: in which sense gravity may be defined, a relative property of found, which, with respect to some other, is the effect of a lesser number of vibrations accomplished in the same time, or of vibrations of a longer duration. In which sense also, acuteness is the effect of a greater number of vibrations, or vibrations of a shorter duration.

If the vibrations be isochronous, the found is called musical, and is said to continue at the same pitch. See CHORD and STRAIN, in *Music*.

If two or more sounds be compared in the relation of gravity, &c. they are either equal or unequal, in the degree of tone. Such as are equal, or produced by isochronous vibrations, are called UNIONS.

The unequal, including, as it were, a distance between each other, constitute what we call an interval in music; which is properly the difference, in point of gravity, between two founds.

Upon this inequality, or difference, does the whole effect depend; and in respect hereto it is, that these intervals are divided into CONCORDS and DISCORDS.

GRAUPEN, a term used by the German miners to express the residuum of any ore after the regulus, or metalline part, is run from it. Thus the ores of bismuth leave behind them, after the regulus is melted off, an earthy substance called *bismuth graupen*, with which, mixt with flint and an alkali, they make a kind of smalt, not distinguishable from the true smalt made from cobalt. Phil. Trans. N° 390.

GRAVY, in *Cultery*, &c. the juices of Bells, or fish, obtained from them by coction, elixation, friction, or the like.

GRAY, or GREY, a mixed colour, partaking of the two extremes, black and white. See DRINK.

In the *Maneys* they make several sorts of gray: as the *branded* or *blackened* gray, which has spots quite black, dispersed here and there. The *dappled* gray, which has spots of a darker colour than the rest of the body. The *light* or *silver* gray, wherein there is but a small mixture of black hairs. The *bad* or *iron* gray, which has but a small mixture of white. And the *brownish* or *lamb-coloured* gray, where there are bay-coloured hairs mixed with the black.

GRAY, in *Zoology*, a name given in some counties of England to the BADGER.

GRAY is also used in some places for a species of wild-duck, more commonly known by the name of the *geduall*. See DECK.

GRAYLING, or UMBER, the English name for the fish called by authors *thymallus*, and *thymus*, and by Artedi made a species of COREGONUS, and the *salmo thymallus* of Linnæus.

It is of a long and flattened body, the belly is somewhat broad, and the back rigid and thin. It seldom exceeds a pound, or at the utmost a pound and half weight. The trides are silvery, tinged with yellow; the teeth very minute, fringed in the jaws and roof of the mouth, but none on the tongue; the head is dusky; the covers of the gills of a glossy green; the back and sides of a fine silvery grey, varied slightly, when the fish is just taken, with blue and gold; the side line is straight; the scales are large, and the lower edges dusky, forming faint rows from head to tail; the first dorsal fin has twenty one-rays; the three or four first are the shortest, the others almost of equal length; this fin is spotted, but all the others are plain; the tail is much forked.

It is caught in the fresh rivers and clear rapid streams, chiefly in the mountainous counties of England, and in the like situations in Germany, and other kingdoms, and is one of the finest tasted of all the fresh water fish. It is common in Lapland, where the guts of it are used instead of rennet to make the cheese, which they get from the milk of the rein-deer. It is a voracious fish, rises freely to the fly, and will very eagerly take a bait. It feeds on worms, and spawns in May. See *Tak. of Fishes*, N° 7. Willughby and Pennant.

GRAYMILL, in *Botany*. See CROMWELL.

GREASE, among *Farriers*, &c. a swelling and gourdiness of the legs of a horse, very frequently happening after a journey.

If the *grease* be an attendant of some other disease, it will be in vain to attempt the cure before the disease be removed that is the original cause of it; and therefore, if it be a heule, the yellow, or the farcin, &c. the directions given for those diseases are to be followed, and in the mean time proper applications are to be used outwardly for the *grease*.

If the *grease* proceed from the common and ordinary accidents, and the horse has no other distemper upon him, then applications that are peculiar to this distemper are to be followed. In general, keeping the heels clean, by washing them with soap-suds, chamber-lye, or vinegar and water, moderate exercise, a large and convenient stall, with good air, are the best remedies.

When the heels are cracked, and discharge a nauseous matter, or are full of hard fish, after cutting off the hair, poultices, made of boiled turnips and lard, with a handful of powdered linseed, or oatmeal and rye-flour, with a little common turpentine and hog's lard, boiled up with strong beer grounds, or red wine lees, should be applied to them, for two or three days, over the digestive ointment: these will promote a discharge, which may be dried up with the following wash, take white vitriol and burnt-alum, of each two ounces; Egyptianum, one ounce; lime-water, a quart or three pints; wash the sores with a sponge dipped in this mixture three times a day, and apply the common white ointment, spread on tow, to which may be added sugar of lead, in the proportion of two drams to an ounce of ointment. If the disorder has advanced to a greater height, and the horse has been well fed and pampered, it may be necessary to have recourse, not only to bleeding, rowels, and repeated purging, but to the use of diuretic medicines. For this purpose the nitre balls may be given in the quantity of two ounces a day, for a month or six weeks; they may be either mixed with honey, or given in the horse's feed; one dram of camphor may be added to the nitre. The legs should be also fomented twice a day with discutient fomentations, in which a handful or two of wood-ashes has been boiled: the above poultice applied, the sores dressed with the green ointment, and when they are properly digested, dried up with the wash already recommended. If the sores are very foul, they should be dressed with two parts of the wound ointment, and one of Egyptianum, over which the following preparation, spread on thick cloths, should be rolled on: take of black soap one pound, honey half a pound, burnt alum four ounces, powdered verdigrise two ounces, and a sufficient quantity of wheat flour. If the diuretic balls should not succeed with this treatment, they must be changed for the antimonial and mercurial alteratives. Bartlett's Farriery.

GREASE makes, is a distemper incident to horses, in which the fat is melted by violent exercise in hot weather, and discharged with their dung. This disease is always attended with a fever, heat, restlessness, flaring and trembling, inward sickness, shortness of breath, and sometimes with the symptoms of a pleurisy. For the cure, bleed plentifully, and repeat it for two or three days successively in smaller quantities; put in two or three rowels and administer cooling emollient glysters. Let the horse drink plenty of warm water or gruel, with cream of tartar or nitre. When he has recovered his appetite, and the fever is removed, gentle aleoic purgings, consisting of half an ounce or six drams of fine salts, should be given once a week for a month or six weeks. The purge may be prepared thus: take of Succotrine aloes six drams; of gum guaiacum, half an ounce; of diaphoretic salmony and powder of myrrh, of each two drams; and make them into a ball with syrup of buckthorn: or it may be prepared with an ounce of aloes, six drams of diaphoretic, and a spoonful of oil of amber. The diuretic nitre medicine recommended in the article GREASE will be found of great use. Bartlett's Farriery.

GREASE, among *Hunters*, denotes the fat of a boar or hare.

GREAT, a term of COMPARISON, denoting a thing to have more extension than some other to which it is referred.

Thus we say, a great space; a great distance; a great figure; a great body, &c.

GREAT is likewise used figuratively, in matters of morality, &c. to signify ample, noble, elevated, extraordinary, important, &c.

Thus we say, Shakspeare was a great genius; queen Elizabeth had a great soul; Cromwell was a man of great design; Da Vinci, a great painter; Galileo a great philosopher; Bossu a great critic, &c.

GREAT is also a title or quality appropriated to certain princes, and other illustrious personages.

Thus we say the great Turk; the great Mogul; the great cham of Tartary; the great duke of Florence, &c.

GREAT is also a surname bestowed on several kings and emperors.

Thus we say, Alexander the *great*; Cyrus the *great*; Charles the *great*, or Charlemagne; Henry the *great* of France, &c. So the English frequently say Edward the *great*, or the *great* Edward; William the *great*, meaning king William III. or the *great* William. The French say, Louis the *great*, *le grand*, speaking of the late Louis XIV. Giles of Paris says, Charlemagne first got the surname *great* from the tallness and eminence of his stature. Helgaud adds, that Hugh the *great* of France was thus denominated on account of his great piety, goodness, &c.

GREAT is also applied to several officers, who have pre-eminence over others.

Thus we say, the lord *great* chamberlain; the *great* marshal of Poland, &c.

GREAT circles of the sphere. See *Great CIRCLES*.

GREAT circle sailing. See *SAILING*.

GREAT apparatus. See *APPARATUS*.

GREAT artery. See *ARTERY*.

GREAT hairam. See *BAIRAM*.

GREAT hairs. See *Ussa major*.

GREAT dialling. See *DIACHYLON*.

GREAT gun. See *CANNON* and *GUN*.

GREAT letters. See *CAPITALS*.

GREAT mase. See *MAIS*.

GREAT officers. See *OFFICERS*.

GREAT repeat. See *REPEAT*.

GREAT seal. See *SEAL*.

GREAT tithes. See *TITHES*.

GREAT wardrobe. See *WARDROBE*.

GREAT wheel, in *Clot* or *Water-work*, is that wheel which the weight, spring, or force, first moves.

GREAT work, in *Chemistry*, is the alchemical process whereby gold is made, or pretended to be made.

GREAT year. See *PLAYONIC year*.

GREATER baron. See *BARON*.

GREATER diaphanous digram. See *DISSIS*.

GREATER excommunication. See *EXCOMMUNICATION*.

GREATER fish. See *FISH*.

GREATER hexachord. See *HEXACHORD*.

GRIEBE, in *Ornithology*, is classed by Linnæus under the genus of *COLUMBUS*. See *DIVER*.

The distinguishing characters of this species of birds are, that the bill is strong, straight, and sharp-pointed; that they have no tail, and that the legs are flat, thin, and serrated behind with a double row of notches. The *great crested grebe*, or *cygnus cristatus* of Linnæus, has between the bill and eyes a stripe of black naked skin, and on the head a large dusky crest separated in the middle; the cheeks and throat are surrounded with a long pendant ruff of a bright raven colour, edged with black; the chin is white; from the bill to the eye is a black line, and above that a white one: the hind part of the neck and back are of a sooty hue; the rump is covered with long soft down; the breast and belly are of a most beautiful silvery white, glossy as satin, and applied to the same uses with those of the *tipper grebe*. They breed in the mires of Shropshire and Cheshire, and in the east fen in Lincolnshire, where they are called *gawts*. The bird sits and hatches its eggs in a nest floating on the water, among the reeds and flags. It preys on fish, and is almost perpetually diving, and is never seen on land; the flesh is rank, but the fat is recommended in rheumatic pains, cramps, and palsy; contraindications. Pennant. *Tak. II. Birds*, N° 15.

The *little or carck grebe*, or *cygnus arvensis* of Linnæus, is the *disapper*, or non-chick of other writers. The *tipper grebe*, or *cygnus arvensis* of Linnæus, called also *cygnus major*, *greater lan*, and *greater dish-bird* by other writers, differs from the *great crested grebe* in being rather less, and wanting the crest and ruff. This species is scarce in England, but is common in the winter-time on the lake of Geneva, where they appear in flocks of ten or twelve. They are killed for the sake of their skin, the underside of which being dressed with the feathers on, are made into muffs and tippets. Pennant. *Tak. II. Birds*, N° 16.

GREE, in our *Law Books*, signifies agreement, contentment, or good liking. Thus, to make *gree* to the parties, is to satisfy them for offence done. "Judgment shall be put in sufficiency, till *gree* be made to the king of his debt." Stat. 25 Edward III.

The word is formed from the French *grei*, *good will*, *good liking*, or *allowance*.

GREEK language, or *ancient GREEK*, is the language spoken by the ancient Grecians, and still preserved in the works of their authors, as Plato, Aristotle, Iococrates, Demosthenes, Thucydides, Xenophon, Homer, Hesiod, Sophocles, Euripides, &c.

The *Greek* has been preferred entire longer than any other language known, notwithstanding all the revolutions that have happened in the country where it was spoken. See *ENGLISH*.

VOL. II. N° 158.

Yet, from time to time of the removal of the seat of empire to Constantinople, in the fourth century, it has been gradually altering: the alterations at first did not affect the analogy of the tongue, the construction, inflections, &c. There were only new words, new riches acquired by taking in the names of new dignities and offices, and the terms of art it was before unacquainted with; but, at length, the incursions of the Barbarians, and especially the invasion of the Turks, wrought much more considerable alterations.

The *Greek* has a great copia or stock of words: its inflections are as remarkable for their variety, as those of most of the other European tongues for their simplicity. It has three numbers, singular, dual, and plural, and abundance of tenses in its verbs, which makes a variety in discourse, prevents a certain dryness which always accompanies a too great uniformity, and renders the language peculiarly fit for all kinds of verse.

The use of the participles of the aorists and perfects, together with the compound words, wherein it abounds, give it a peculiar force and brevity, without taking any thing from its perspicuity.

The proper names in the *Greek* language are significant, as in the oriental as well as most of the modern languages, where the learned still find some, though remote, character of their origin.

The *Greek* was the language of a polite people, who had a great taste for arts and sciences, which they cultivated with success. In the living tongue are still preserved a vast number of *Greek* terms of art; some descended to us from the Grecians, and others formed anew. When a new invention, machine, right, order, instrument, &c. has been discovered, recourse has been commonly had to the *Greek* for a name; the facility wherewith words are there compounded, readily affording us names expressive of the use, effect, &c. of such instruments. Hence *oreometer*, *thermometer*, *barometer*, *micrometer*, *logarithm*, *telescope*, *microscope*, *heliometer*, &c.

GREEK, modern or vulgar, is the language now spoken in Greece, and called *Ρωμαϊκή γλώσσα*, from Constantinople being called *Roma Nova*.

There have been few books written in this language, from the taking of Constantinople by the Turks; scarce any thing but some catechisms, and the like pieces, compiled or translated into the vulgar *Greek*, by the Latin missionaries.

The native *Greeks* are contented to speak the language without cultivating it; the Turkish politics not allowing any of the subjects of their estates to apply themselves to the arts and sciences.

It is not easy to assign the precise difference between the vulgar and the *ancient Greek*: it consists of the terminations of nouns, pronouns, verbs, and other parts of speech, which make a difference between those two languages much like that observed between some of the dialects of the Italian or Spanish: we influence in those languages, as being the most known; but we might have said the same thing of the Hebrew, Slavonic, &c. dialects.

The *modern Greek* also curtails words, runs them into one another, and adds a sort of enclitic particles in the end of them: it confounds the vowels *u*, *i*, *a*, and the diphthongs *ai* and *au*, which they pronounce and often write only *ia*. They likewise often confound cases, moods, tenses, and particles. See *Brettreed's* Inquiry concerning the Diversity of Languages, &c. chap. 2. Besides, the *modern Greek* has divers new words not in the ancient; particularly several participles which appear as explicatives, and which are introduced to characterize certain tenses of verbs, and other expressions, which would have had the same meaning without such particles, had custom dispensed with them; divers names of dignities and offices, unknown to the ancient *Greeks*; and abundance of words borrowed from the vulgar tongues of the neighbouring nations.

Accordingly one may distinguish three ages of the *Greek* tongue: the first ends at the time when Constantinople became the capital of the Roman empire; not but there were several books, especially *orise* fathers of the church, written with great purity after that time; but as religion, law, and policy, both civil and military, began then to introduce new words into the language, it seems necessary to begin the second age of the *Greek* tongue from that epocha; which lasted to the taking of Constantinople by the Turks, where the last age commences.

GREEK names. See *ACCENT*.

GREEK Bible. See *BIBLE*.

The New Testament was translated into *modern Greek* by Maximus a monk, who flourished about the year 1630. It was undertaken at the request of Cornelius Haga, the Dutch ambassador at the Port of Constantinople, and is praised and recommended by the patriarch Cyrillus Lucaris. An edition of this version, with the *ancient Greek*

in one column, and the modern *Greco* in another, was published at Geneva in 1632. There was another edition printed at London in duodecimo in the year 1703. The translation appears to be very literal, and so close as to be sometimes obscure.

GREEK church is that part of the Christian church which is established in Greece; extending likewise to some other parts of Turkey.

It is thus called in Europe, Asia, and Africa, in contradistinction from the *Latin* or *Romish* church; as also the *Eastern* church, in distinction from the *Western*.

The Romanists call the *Greek* church the *Greek schism*, because the Greeks do not allow the authority of the pope, but depend wholly, as to matters of religion, on their own patriarchs. They have treated them as schismatics ever since the revolt, as they call it, of the patriarch Photius. See CHURCH.

GREEK year. See YEAR.

GREEN, one of the original colours of the rays of light.

Grass and herbs, and even all vegetables in places exposed to the open air, are *green*; and those in subterraneous places, or places inaccessible to the air, white and yellow. Thus when wheat, or the like, germinates underground, it is white or yellow; and when it is in the open air *green*, though this too is yellow before it be *green*.

GREENS, artificial, are very rarely simple colours, but produced by mixture of yellow and blue.

Two powders, the one blue, and the other yellow, well mixed, appear perfectly *green*; though, when viewed with a microscope, we observe a chequer of blue and yellow.

The tincture of freed roses with oil of tartar per deliquium, or with spirit of sal ammoniac, produces *green*. The tincture of many red flowers is changed into *green* by an alkali. The tincture of red roses, and the yellow tincture of crocus, or the blue tincture of cypaous, and the white spirit of sal ammoniac, produce *green*. The solution of verdigrise becomes colourless by the addition of the spirit of nitre, and by the addition of the oil of tartar it becomes *green* again.

The dyes make divers shades, or casts of *green*, as *light green*, *yellow green*, *grass green*, *laurel green*, *sea green*, *dark green*, *parrot green*, and *celadon green*.

All the *greens* are first dyed blue, then taken down with woad, verdigrise, &c. and then *ground* with the woad, there being no one ingredient that will give *green* alone. See DYEING.

GREEN, mountain, or Hungary GREEN, is a sort of *greenish* powder found in little grains, like sand, among the mountains of Kernaust in Hungary, and those of Moldavia. Though some hold, that this mountain *green* is fallacious, and the same with that the ancients called *ful aris*, prepared by calling water, or rather wine, on copper red-hot from the furnace, and catching the fumes thereof on copper plates laid over for that purpose; yet by dissolving copper plates in wine, much as in making verdigrise. The painters make use of this colour for *grass green*. It is sometimes counterfeited by grinding verdigrise with ceruse.

GREEN, calined, and distilled GREEN. See VERDIGRISE.

GREEN, Prussian. See the process for making Prussian BLUE.

GREEN, for. See COLOURS FROM FRUITS, BUCKTHORN, and SASS-PARILLA.

GREEN, Saxon, an extremely beautiful *green* colour, the process of dying which is this: the cloth or silk is first to be dyed a *Saxon blue*, in the following manner. Having ground nine parts of indigo with twenty of red arsenic into a fine powder, add forty eight parts of strong spirit of vitriol; which mixture swells, grows hot, and emits a sulphurous smell. After standing in a moderate warmth for twenty-four hours, pour off the liquid part, which will be of an extremely deep blue. A small quantity of this liquor, dropped into hot water, instantly spreads, tinges it of a fine light blue, and fits it for dying the

prepared wool, cloth, or silk; and by increasing or diminishing the proportion of the blue composition, the colour may be rendered deeper or lighter. This, Dr. Lewis says, is the method used for preparing the blue composition by the dyers of Norwich, who purchased this secret from Saxony.

The cloth or silk, thus dyed blue, is next to be dipped in the yellow decoction of weld or fustic, and the desired colour will be obtained.

Or the subject may be dyed *green* at one operation, by boiling it for a little time in a mixture of the blue and yellow liquors.

By thus combining any blue and yellow dyes, in different proportions, all the shades of *green* may be produced, from the bluish *green* of the cabbage-leaf to the greenish yellow of the olive.

GREEN soap. See SOAP.

GREEN copperas. See COPPERAS.

GREEN earth. See VERDIGRIS, and TERRE VERTE.

GREEN finch, the English name of a species of *LOxia*, being the *Isia chloris* of Linnaeus, which has a strong tinge of *green* diffused over all its body; the wings and tail are black, but both variegated with a beautiful yellow.

This bird may be easily tamed, by carrying it into the dark, and putting it upon one finger, and gently touching its breast with a finger of the other hand. If a few strokes and caresses of this kind, and letting in the light by degrees, it will eat any bruised feed out of the hand, and afterwards continue tame. See CHLORIS.

GREEN fish. See GAD-FISHERY.

GREEN glass. See GLASS.

GREEN-hen, or green-bag, in our Old Writers, the same with *vert* in forcella, &c.

GREEN hides, are those not yet tanned, or dressed, but such as are taken off from the carcasses. See HIDE, and CURRYING.

GREEN mustard, an English name for the herb *DITTANDER*, or pepperwort.

GREEN shad, in Ornithology, the *haloptilus galeus* of Linnaeus. See LIMOSA.

GREEN shiff. See CHLOROSIS.

GREENS flower, the name of an ancient custom within the manor of Writtle in the county of Essex; which is, that every tenant, whose fore-door opens to Greenbury, shall pay an half-penny yearly to the lord, by the name of *greens flower*. Bount.

GREEN wax is used where chests are delivered to the sheriffs out of the exchequer, under the seal of that court, made in *green wax* to be levied in the several counties.

GREEN wood. See BROOM.

GREEN winter. See WINTER GREEN.

GREENCLOTH, a board, or court of justice, held in the counting-house of the king's household, for the taking cognizance of all matters of government and justice within the king's court royal; and for correcting all the servants therein, that shall any way offend.

To this court also belongs the authority of maintaining the peace for twelve miles round the king's court, wherever it shall be, excepting at London.

The judge of this court is the lord steward, assisted by the treasurer, comptroller, cofferer, clerks of the *greencloth*, &c. It takes its name, *greencloth*, from a green cloth spread over the board where they sit, whereon are the arms of the counting-house.

GREENCLOTH, clerks of the, are three officers of the board of *greencloth*, who attend there, and have business assigned them by the board. All bills of compromise, relating to the office, are summed up, and allowed by the clerks comptrollers, and audited by the clerks of the *greencloth*.

They also appoint the king's, queen's, and household's diet, and keep all records, ledgers, and papers, relating thereto; make up bills, parcels, and debentures for salaries, &c. and provisions and necessaries for the officers of the pantry, buttery, cellar, &c.

GREENHOUSE, or conservatory, a house of shelter in a garden; continued for preserving the more tender and curious exotic plants, which will not bear the winter's cold abroad in our climate.

Greenhouses, as now built, serve not only as conservatories, but likewise as ornaments of gardens; being usually large and beautiful structures, in form of galleries, where in the plants are handsomely ranged in cases for the purpose.

The length of *greenhouses* must be proportioned to the number of plants intended to be preserved in them, and cannot therefore be reduced to rule; but their depth should never be greater than their height on the clear, which, in small or middling houses, may be sixteen or eighteen feet, but in large ones from twenty to twenty-four feet; and the length of the windows should reach from about one foot and a half above the pavement, and within

within the same distance of the ceiling, which will admit of a cornice round the building over the heads of the windows. Their breadth cannot be in proportion to their length; for if in the largest buildings they are more than seven or seven feet and a half broad, they will be extremely heavy and inconvenient. The piers between the windows must be as narrow as may be, to support the building; for which reason they should either be of stone, or of hard burnt bricks.

If the piers are made of stone, they should be thirty inches wide in front, and sloped off behind to about eighteen inches, by which means there will be no corners to take off the masonry of the sun. If they are of brick, they will require to be at least three feet in front, but they should be in the same manner sloped off behind. Over the *greenhouse* may be rooms for drying and preserving foods, roots, &c. and behind it a place for tools and other purposes; and both these behind, and the rooms above, will be of great use in keeping off the frosts, so that the wall between these need not be of more than two bricks and a half in thickness.

The floor of the *greenhouse*, which should be laid either with Bremen squares, Parbeck stone, or flat tiles, must be raised two feet above the surface of the adjoining ground, or if the situation be damp, at least three feet; and if the whole is arched with low brick arches under the floor, they will be of great service in preventing damp; and under the floor, about two feet from the front, it will be very advisable to make a flag of ten inches wide, and two feet deep; this should be carried the whole length of the house, and then returned back along the hinder part, and there be carried up into funnels adjoining to the tool-house, by which the smoke may be carried off. The fire-place may be contrived at one end of the house, and the door at which the fuel is put in, as also the ash-grate, may be contrived to open into the tool-house, and the fuel being laid in the same place, the whole will be out of sight. Bradley recommends the new stove invented by M. Gauger, and published by Dr. Desaguliers. Bradley also advises, that the front of *greenhouses*, in the colder parts of England, be built in a sweep or semicircle, so that one part or other of it may receive the sun's rays all day. The use of fires must, however, be very sparing in this place; and it is not one winter in three or four that will require them in any part, only when the weather is very severe, and the frost cannot well be kept out any other way, this is an expedient that is good to have in readiness, as it may save a whole house of plants. Within side of the windows, in front of the *greenhouse*, there should be good strong shutters, made with hinges, to fold back close to the piers, that they may not obstruct the rays of the sun. These shutters need not be more than an inch and a half thick. The back part of the house should be either laid over with stucco, or plastered with mortar, and white-washed, in order to prevent the frosty air from penetrating through the walls. When the *greenhouse* is waistered, the walls should be plastered with lime and hair behind the waister, to keep out the cold; and the waister, as well as the ceiling, and every part within the house, should be painted white, for the reflection of the sun's rays. There must be a number of trellis, with forms of wood upon them, to support the pots of plants, the tallest to be placed hindmost, the lowest within four feet of the windows; and the rows of plants should rise gradually, so that the heads of the second row should be entirely above the first; and behind them there should be a space of at least five feet, for the convenience of watering the plants, and for a free circulation of air. It has been observed that the placing of the eschophiums, cereuses, and other succulent plants among orange-trees, and other common *greenhouse* plants, is always destructive of them, by making them receive an improper sort of eluvium, which plants of that kind inhale very freely. They should therefore be placed in two wings built at each end of the *greenhouse*, which, if well contrived, will be a great beauty, as well as use, to the building. These wings may be made capable of a greater warmth also by more flues, and may be made to contain a hot-bed of tanners bark for the raising many of the tender plants, natives of warm climates.

While the front of the *greenhouse* is exactly south, one of the wings may be made to face the south-east, and the other the south-west. By this disposition the heat of the sun is reflected from one part of the building to the other all day, and the front of the main *greenhouse* is guarded from the cold winds. These two wings may be so contrived as to maintain plants of different degrees of hardness, which may be easily effected by the situation and extent of the fire-place, and the manner of conducting the flues: the wing facing the south-east is evidently the most proper for the warmest flore; this may be divided

in the middle by a partition of glass, with glass doors opening from one division to the other. In each of these there should be a fire-place, with flues carried up against the back wall, through which the smoke should be made to pass, as many times the length of the house as the height will admit of the number of flues; for the longer the smoke is in passing, the more heat will be given to the house, with a less quantity of fuel. The other wing, facing the south-west, should be divided and furnished with flues in the same manner; and thus different degrees of heat may be obtained, according to the season, and the particular sorts of plants that are to be preferred. If there are no sheds behind these wings, the walls should not be less than three bricks thick, and the back part, having sloping roofs, which are covered with tiles or slates, should be lined with reeds, &c. under the covering. The sloping glass of these houses should be made to slide and take off, so that they may be drawn down more or less, in warm weather, to admit air to the plants; and the upright glasses in front may be so contrived, as that every other may open as doors upon hinges, and the alternate glasses may be divided into two; the upper part of each should be so contrived as to be drawn down like shutters, so that either of them may be used to admit air, in a greater or less quantity, as there may be occasion.

Miller. As to the management of the plants herein, Mortimer recommends the opening of the mould about them, from time to time, and sprinkling a little fresh mould in them, and a little warm dung on that; as, also, to water them when the leaves begin to wither and curl, and not otherwise; which would make them faster, and be scilicet; and to take off such leaves as wither, and grow dry. It is a general rule among gardeners, to fit exotic plants in the *greenhouse* about the second week in September; and to take them out again about the middle of May; though there should be some distinction made herein; the tenderest sorts from places near the line, as the aloes, &c. being to be confined longer to the *greenhouse* than oranges, myrtles, &c.

GREENLAND fishery. See WHOLE-FISHERY.

GREENLAND company. A joint stock of 20,000*l.* was by statute to be raised by subscribers, who were incorporated for fourteen years from the first of October, 1802, and the company to use the trade of catching whales, &c. into and from Greenland, and the Greenland trade; they may make bye-laws for government, and of the persons employed in their ships, &c. Stat. 4 and 5 W. III. cap. 17. This company was farther encouraged by parliament in 1805; but partly by unskillful management, and partly by real losses, it was under a necessity of entirely breaking up, before the expiration of the term assigned to it, ending in 1807. But any person who will adventure to Greenland for whale-fishing, shall have all privileges granted to the Greenland company, by 1 Anne, cap. 16. and thus the trade was again laid open. Any subjects may import whale-fins, oil, &c. of fish caught in the Greenland seas, without paying any customs, &c. Stat. 10 Geo. I. cap. 16. And ships employed in the Greenland fishery are to be of such burthen, provided with boats, for many men, fishing lines, harping irons, &c. and be licensed to proceed; and on their return shall be paid 20*l.* per ton bounty, for whale-fins, &c. imported. 6 Geo. II. cap. 33. See WHOLE-FISHERY.

GREENWICH hospital. See HOSPITAL.

GREGARIOUS birds, are such as do not live solitarily, but associate in flocks or coveys, a great many together in company.

GREGORIAN epochs, in the epochs, or time, whence the Gregorian calendar, or computation, took place.

The year 1780 is the 108th year of the Gregorian epoch.

GREGORIAN year. See YEAR.

GRENADA. See GRANADO.

GRENADIER. See GRANADIER.

GRENAILLE, a name given by the French writers to a preparation of copper, which the Chinese use as a red colour is some of their finest chimis, particularly for that colour which is called *ail-rouge*, or *red in oil*. The Chinese ware coloured with this is very dear. The manner in which they procure the preparation is that: they have in China no such thing as silver-coined money, but they use in commerce bars, or masses of silver; these they pay and receive in large bargains; and among a nation so full of fraud as the Chinese, it is no wonder that these are often adulterated with too great an alloy of copper. They pay, however, in this state in the common payments. There are some occasions, however, such as the paying the taxes and contributions, on which they must have their silver pure and fine: on this occasion they have recourse to certain

certain people, whose sole business it is to refine the silver, and separate it from the copper and the lead it contains. This they do in furnaces made for the purpose, and with very convenient vessels. While the copper is in fusion, they take a small brush, and dip the end of it into water; then striking the handle of the brush, they sprinkle the water by degrees upon the melted copper; a sort of pellicle forms itself by this means on the surface of the matter, which they take off while hot with pincers of iron, and immediately throwing it into a large vessel of cold water, it forms that red powder, which is called the *granaile*; they repeat the operation every time they in this manner separate the copper; and this furnishes them with as much of the *granaile* as they have occasion for in their china works. Observations sur les Costumes de l'Afrique, p. 309.

GRENHAM village. See COLLEGE.

GRESLING, in Ichthyology, a name given by the Germans to the *phoxinus phoxinus*, or common gunglow, which is very frequent in their smaller rivers.

GRESSURA, a word used by some writers, to express the part between the pulchra and the anus. See PARTIUM.

GREVE, GREVEA, among our Ancient Writers, is a denomination of power and authority; signifying as much as *comes* or *viceroy*. See COMITUS and VISCOUNT.

The word is formed from the Anglo-Saxon *grith*, *grith*. Thus Horace: *Greve dictor, id est jurado ab eo grith*, i. e. *patem ex illis factis, qui patria inferant vi*, i. e. *misericordiam vel malum*.

Lambard makes *grith* the same with *reue*. Hence, also, the words *forgrith*, *forgrithen*, &c. which were anciently written *forgrithen*, *forgrithen*, &c.

GREWIA, in Botany, a genus of the *myrsinaceae* polyanthia class. Its characters are these: the flower hath a five-leaved empalement; five petals, which are indented at their base, where is situated a scaly nectarium to each; and hath many bristly stamina; in the centre is situated a roundish germen, which is lengthened in form of a column, and becomes a four-cornered berry with four cells, each including one globular seed. Miller reckons two species, natives of Africa, and Linnaeus four.

GREWT, in Mineralogy, a word used by our miners to express earth, but particularly that earth found in the flat countries, and in the banks of rivers, in their fetches after mineral veins, which is different in colour and nature from the rest of the bank or bottom. This they always understand to have been washed off from the neighbouring hills, in the time when the flood-flows, by which they train their new mines, were also washed down, that is at the universal deluge; and this wherever found, proves of great use to them in these researches, as it shews which way the wash from the hill has run, and directs them how to trace the rest, and where to look for the flood-flows with any probability of success. They generally examine the banks of rivers, where they have been worn away by land floods, in order to find these *grewt*, and then examine, in a straight line with the next hill, though four or five miles off; and if there be any mine there, they generally meet with flood-flows, as tokens of it in the way. Phil. Trans. N° 69.

GREY. See GRAY.

GREY, in Ichthyology, an English name for a truttaeous fish, the *salmo trutta* of Linnaeus, caught in many of the rivers of England. It is a very large fish, often growing to the full size of the larger salmon, but differing from that species, in the body being broader, and the head large in proportion; in the jaws are four rows of teeth, and on the tongue are eight teeth; the back and sides, above the lateral line, are of a deep grey colour, spotted with a number of purplish spots, whence its name; the belly is silvery; its tail is not forked, and its flesh is much finer tasted than the salmon; and in the places where both are to be had, the grey sells at the larger price. It comes up into the fresh-waters in the month of August, and is a very voracious fish.

Mr. Pennant relates this to be the *semin* or *shemin* of South Wales, which is very common in the neighbourhood of Carmarthen. This fish appears in the Elk, in Cumberland, from July to September, and is then in spawn. The lower jaw grows hooked, when it is out of season. The inhabitants of the North of England and of South Wales consider this fish as a distinct species from the Salmon.

GRASS JR. See GRASS.

GREYHOUND. See HOUND and DOG.

GREYHOUNDS, in Astronomy. See CANES VENATICI.

GREYLAG gulls. See GULLS.

GRISAS, in Botany, a genus of the *polyanthia monogynia* class; the characters of which are, that the flower hath four petals; the calyx is divided into four segments; and the fruit is a drupe, containing an eight-furrowed nucleus.

GRICE, a term used by country persons for a young wild boar.

GRIEF. The influence of this passion on the body is very great, so as often to destroy all appetite and desire of meat, either by inspiring men with a distaste for life, or by a mechanical influence; because food taken at such a time makes but bad nourishment, fitted to corrupt the blood than prolong life; in which account it is assigned as a physical cause for the FASTING practised among the heathens. The influence of this passion extends itself even to brutes; which, when indisposed, not only take no pains to provide themselves food, but also refuse it when laid before them. Vide Mem. Acad. Inscript. tom. v. p. 50, seq. This passion has been found to lessen EXPIRATION and URINE.

GRIELUM, in Botany, a genus of the *decandria pentagyna* class; the characters of which are, that the calyx is divided into five segments; the flower has five petals; and the fruit consists of five monopericarpous pericarps.

GRIFFON, GRIFON, γρυψ, in Natural History, the name of an imaginary bird of prey, of the eagle kind.

The ancients speak fabulously of the griffin; they represent it with four legs, wings, and a hawk; the upper part representing an eagle, and the lower a lion; they suppose it to watch over gold-mines, hidden treasures, &c.

The animal was consecrated to the sun; and the ancient painters represented the chariot of the sun as drawn by griffins. M. Spanheim observes the same of those of Jupiter and Nemesis.

The griffin, in Scripture, is that species of the eagle called in Latin, *effragus*, the *effrag*; and גריף, of the verb גרף, *parvi*, to break.

The griffin is frequently seen on ancient medals; and is still borne in coat-armour.

Guillem blazons it rampant, allying, that any very fierce animal may be so blazoned, as well as the lion. Sylvester, Morgan, and others, use the term *segriffant*, instead of rampant.

This is also an ornament of architecture in constant use among the Greeks, and was copied from them, with the other elegancies of architectural enrichments, by the Romans. See SERVUS.

GRIG, in Ichthyology, a name frequently used for the sand eel, or *ammodytes*.

These are common in the Thames, and are distinguished from the common sort by having a larger head, a blunter nose, thicker skin, and less fat; and they are not so much esteemed, and seldom exceed three or four ounces in weight.

GRILLADE, in Cookery, meat broiled on the gridiron; thus called from the French *griller*, to broil.

The word is also used for the browning of any dish, by rubbing a red-hot iron over it. To *grill oysters*, is to put them into scollop-shells, season them with salt, pepper, and parsley shred, and pour their own liquor to them, covering them with grated bread, broiling them half an hour on the fire, and broasting them with a red-hot iron. Shrimps are *grilled* after the same manner.

GRINDSTONE, in Botany, in Natural History, is a very coarse, rugged, rough, and harsh stone, of a yellowish brown colour, composed of an irregular grit, cemented together by a coarse and debased terrene crystalline matter, and intermixed with a very few glittering spangles of white talc; it cuts freely, but bears no polish; it is pervaded by water, will not strike fire with steel, is not acted upon by acids, and burns to a deep red colour, but acquires no hardness. It is chiefly dug in the northern counties of England, and used for *grind-stones*, whence its name.

GRINDING, in Metallurgy, the act of breaking or comminuting a solid body, and reducing it into powder, dust, flour, farina, or the like.

Grinding is one of the species of dissolution. The painters colours are ground on a marble or porphyry, either with oil or gum-water.

Some late physicians contend, that DIGESTION is performed by grinding the food in the stomach. It is alleged, that every part in the body is a vessel or vessels; and all the vessels have a motion of systole and diastole; all the operations of the body consist in the attrition or grinding of the humours or matters contained in such vessels.

GRINDING is also used for rubbing or wearing off the irregular or superfluous redundant parts of the surface of a body, and reducing it to the desired figure, whether that be flat, concave, or the like.

The grinding of glass is a considerable art, and is such, necessarily requires to be here insisted on; especially that of optic glasses.

Method of GRINDING OPTIC GLASS. For convex glasses, the first object is to provide a dish or basin, within whose cavity the glass is to be formed.

In order to this, they take a piece of brass, copper, iron, or wood, and form it into a segment of a circle, having the radius of the bafon or the dish intended: this done, a bafon is forged by a smith, either of iron or copper, having its cavity exactly fitting or corresponding to the segment above mentioned, though sometimes they chuse to have the bafon cast; in this case, the rules elsewhere delivered for concave mirrors are to be here observed. The figure of the bafon, thus roughly formed, is to be finished in the pewterers lathe, or on a stone mould A, Tab. II. Opticæ, fig. 22. fixed to an iron axis with a pinion BC, moveable by a wheel DE, and that by a winch or handle F. The bafon being ground on the mould till it exactly fit in all parts, they take it off, and cementing it to a wooden block (loaden, if need be, with lead), strew it over with fine-sifted sand, and thus grind it over again on the mould, till all the furrows or scratches be quite taken away.

Lastly, they grind large pieces of glass in a bafon, with fine sand between, till such time as, its surface being well smoothed, there is no longer any opposition to the motion.

Note, the dish is known to be perfectly finished when, a hair being stretched over it, its shadow projected in the cavity, especially in a camera obscura, does not appear any way distorted.

The bafon finished, they proceed to chuse glasses for the purpose: in order to this, lay them on clean paper, and observe what colours are projected thereon; for the same are the colours of the glasses. Always set aside those of the darker colour, and chuse the brighter; but as the whitest and brightest have usually veins, and besides, in tract of time, by the humidity of the air, are apt to rust and lose their polish; for this reason Huygens recommends those a little yellowish, reddish, or greenish; I believe the bluish. A glass is found to be free from hubbles, sands, veins, knots, and spires, by holding it to the sun, and receiving the rays through it on a white paper; for the flaws above mentioned will each project a shadow thereon.

If, instead of lenticular, or at least spherical glasses, you make use of plate-glass, it must be divided and cut with a diamond into squares; and if it be too thick to break otherwise, you may do it by laying it on a table covered with cloth, in such manner as that the side or part to be severed hang over the edge; for, being struck with an iron instrument, in this situation, it easily breaks in the direction of the line drawn by the diamond. Having thus got a square piece, describe two concentric circles thereon with a pair of compasses, one of whose legs carries a diamond; the diameter of the inner circle to be equal to the breadth of the intended lens, and that of the outer somewhat more; and break off the corners, as above directed, and the lesser inequalities take off on a grind-stone, or the like. Examine now whether the piece of glass be every-where equally thick; if it be not, reduce it to such equality by grinding it on an iron plate with sand and water. Lastly, glue or cement the glass thus prepared to a wooden handle NMO, fig. 23. with a cement made of pitch and a fourth part of resin, or one part of wax and eleven of colophony: care to be taken that the base or bottom of the handle NO be equal to the glass, and that the centre of the glass and handle meet together. Smaller lenses, as those used for microscopes, are fixed on with sealing-wax.

Now, to grind the glass, and bring it to the convexity required, smear over the dish equally with fine sifted sand moistened with water; then taking the handle with the glass thereon, work it on the bafon, sometimes this way, and sometimes that, to prevent the form of the bafon from being disturbed, never leaning too hard thereon. When the glass has got the figure of the bafon, clean it well of all the sand and filth adhering, and sprinkle the bafon over with emery moistened in water, grinding the glass thereon till all the roughness and inequalities are taken away: after this, the fine sand used in our glasses may be of service, applied and used as before; remembering to take out the sand, when too much worn, and substitute new in its stead. Some in lieu hereof, chuse several sorts of emery, each finer than the other, or even the powder of flint calcined and pounded. Lastly, grind the same glass in another bafon or dish, which is a segment of a lesser sphere, making use of the like sand as before, till it has got a pretty high rim or margin all around. Because the precision is not here determined accurately enough upon the middle of the glass, by the mere guidance of the hand, some have chose to make use of the following machine, especially for grinding object-glasses.

Fix the dish HI, fig. 24. on a horizontal table; exactly over its centre let the aperture D be, through which pass an iron arm five or six inches long, fastened to the staff

AB; let the other extreme of the staff be fitted into a hole cut in the dish, and fastened therein. Now to grind the glass instead of the dish, take hold of the said staff, and work with sand, &c. as before. Huygens tells us, that he always used first a coarse emery, then a finer powder of the same, which would be fifty seconds in sinking to the bottom of a vessel of water, putting in fresh every half or quarter of an hour: sometimes, too, he used emery of fifty seconds, for three quarters of an hour; then emery of four hundred seconds, for four fifths of an hour; and lastly, emery of forty-five minutes, for a quarter of an hour. The same effect is had from powder of flints, broken in an iron mortar, mixed with water, and stirred sometimes with a wooden spatula, taking the powder as it precipitates in some certain time to the bottom of the vessel, by decanting the water. What remains is to polish the glass.

For a more particular account of the method of grinding and polishing glasses for telescopes, extracted from Mr. Huygens and other authors, by Mr. Molyneux, and comprehending the method of making and polishing the tools, of chusing the glass, of preparing the glasses before they can be ground and polished, of grinding the glasses, and of giving them the last and finest polish, we must refer to Smith's Optics, book iii. chap. I. par. 1.

The late ingenious Mr. James Short, in a paper left with the Royal Society, to be opened and pinned after his death, gives the following directions for working object-glasses of refracting telescopes truly spherical. Prepare two plates or tools of brass, the one convex, and the other concave, being both portions of a sphere of the same radius as the focal length of the object glass you want to have, or rather of a radius somewhat longer than the focal length you want, for a distichal reason; let these plates or tools be between two and three times the breadth of the object-glass desired; or, in long focal lengths, twice the breadth will be sufficient; let these tools be of a sufficient thickness in proportion to their breadth or diameter, and let them be ground with fine emery exactly true to one another, working them alternately, the one above the other, to preserve the same focal length; or, if it is desired longer, you must work the convex above the concave; or, if desired shorter, you must grind the concave above the convex.

After this, you prepare another brass plate or tool, of the same breadth and thickness as the two former, and of the same radius of concavity: its being truly turned on a lathe will be sufficient for this purpose; which tool is to serve afterwards for the polishing of the two surfaces of your object-glass, and therefore called the polishing tool.

Prepare a piece of straw-coloured glass, of the plate-glass kind, of the proper diameter for the object-glass you desire, which ought always to be broader than the proper aperture for that length; let this piece of glass be ground flat, in another tool, on both sides, and as nearly parallel as may be, and somewhat polished, in order to discover whether there are any veins or flaws in the glass. When you are satisfied of the goodness of the glass, you are then to prepare a handle to fasten your glass to. Great care must be taken in this, for fear of bending your glass by the handles Mr. Short advises to take a flat piece of brass, or rather of the concavity of the sphere, to which the glass is to be ground; this piece of brass should not be thicker than two thirds of the thickness of the glass, of a circular form, let its breadth somewhat than the glass itself, and having sides of the same form, at right angles to the flat piece of brass, and these sides ought to be of such a shape as that the fingers may easily apply to it in working, and these sides should be as low as may conveniently be, and no thicker than about two thirds of the glass. This handle is to be fastened to the glass, by warming the glass and handle gently before a fire, and laying some pitch upon the glass thus warmed, till it becomes soft like melted wax; and then laying your brass handle, a little heated, on the pitch, you press it a little, till you are sure there is nothing between the glass and the handle but pitch; you then lay down the glass and handle upon something flat, taking care that the handle is in the middle of the glass, till it is entirely cold. It is very material to know, that the pitch, to be used for fastening the handle to the glass, must be soft pitch, that has never been used nor melted; for any other pitch will infallibly bend the glass.

You then grind your glass in the concave tool with emery, and give it the proper figure and smoothing for the last polish, in the common manner.

In order to give your glass the last polish, which is the most difficult part of the whole work, you are to prepare some pitch for covering the before mentioned polishing concave tool, which is done in this manner: take some pitch, and melt it in an iron ladle, and let it boil

for a quarter of an hour or thereabouts; by this boiling, the pitch, when cold, will become hard and brittle: or you may shorten this operation, by melting equal quantities of pitch and rosin, and then there is no occasion to let it boil so long. Your pitch being thus prepared, you again melt it, and take it off the fire, and let it stand till the pitch becomes pretty cold, or of a thickish consistence: and having warmed the polishing tool a little, to make the pitch stick to it, you pour out of the ladle upon the polishing tool as much pitch as you judge will cover the whole tool, when spread out, to about the thickness of one eighth of an inch; you then invert this tool with the pitch upon it, and press it upon the convex tool, which must be quite dry, clean, and cold, in order to give it the figure of the convex tool: in case it has not spread out so as to cover the whole surface of the polishing tool, you may warm the pitch by holding it before the fire, and pressing it upon the convex tool, as before, till it has entirely covered the surface of the polishing tool; you then plunge it into cold water, till the brass is quite cold.

N. B. In order to know if your pitch is hard enough, you press the edge of the nail of your thumb upon it, and if it receives an impression, the pitch is not hard enough.

You then proceed to prepare this polishing tool, for the last polish of your glass, by grinding this polishing tool upon the convex tool with pretty coarse emery, and a small quantity of water, in the common way that tools are ground one upon another; but this must be done only for a small space of time, and the polishing tool must have no other pressure than its own weight, for fear of some of the emery sticking in the pitch, and you must never allow the emery to grow dry: when you have ground the pitch so as to be all over of the same colour, you then wash the pitch from all the emery with a brush and clean water; after this you take a bottle of water, and holding the pitch tool in a sloping position, you pour water out of the bottle so as to fall upon every part of its surface.

You then place the polishing tool in a horizontal position, and you put upon it some putty, washed from all its gritty particles, but it need not be the finest washed, and you put a good deal of water upon your polishing tool, mixing the putty and it together, and you polish your glass upon this pitch-polisher in the common manner of polishing glasses.

After you have polished your glass about ten minutes, you again grind your polisher upon the convex tool with emery, as before, for fear the pitch has, by working, lost any of its proper figure; and the oftener you do this, the truer will be the figure of your glass; and in this manner you proceed till the glass is quite polished.

You then take your glass off its handle, by holding it before the fire, till it is so warm that you can slide the handle off the glass; and whilst the glass is warm, you take off as much of the pitch as you can with the sharp edge of a knife; you then lay the glass down to cool, and, when quite cold, you drop some spirits of wine upon it; and this, with a cloth, will wipe off the rest of the pitch.

You then examine the centre of the surfaces of your glass; and if it lies to one side of the centre of your glass, mark that place with a spot of ink, and then put on your handle as before, upon the side that is now polished, with its centre over the spot of ink, and grind your glass as before, till the circular remaining part of the glass to be ground is as much distant from the centre of the glass on the other side from the spot as the spot was from the centre of your glass; you then by heat return your handle to the centre of the glass, and proceed to grind and polish this side of the glass as before.

N. B. The concave and convex tools should be ground with fine emery, after you have done one side of your glass; for the oftener these are ground together, you will be the more sure of having your figure true. Phil. Trans. vol. LVIII. p. 507, &c.

Method of Constructing, &c. the Specula of Reflecting Telescopes. The method generally followed by workmen is that proposed by Messrs. Molyneux and Hailey, and published in Dr. Smith's *Optics*: this has been lately improved in a very considerable degree by Mr. Mudge, whose directions, founded on accurate experiments, and practised with success in the construction of telescopes, we shall adopt wherever they differ from those that occur in the book just cited. For making the gages, take a long pole of fir, deal, or any wood, of a little more than double the length of the instrument intended, and strike through each end of it two small steel points, and by one of them hang it up perpendicularly against a wall; then take two pieces of thin plate-brass well hammered, a little thicker than a sixpence, which may be

about an inch and a half broad, and let their length be in proportion to the diameter of the speculum as three to two, so that if the speculum be eight inches diameter, these may be about twelve. Fix each of these strongly with rivets between two thin pieces of waincoat, so that a little more than a quarter of an inch in the breadth may stand out from between the boards. Then fix up these pieces horizontally against the wall under your pole, and thenceforth, as with a beam-compass, strike an arch upon each of them; then file each of them with a smooth file to the arch struck, so as one may be a convex and the other a concave arch of the same circle. These brasses are the gages to keep the speculum, and the tools on which it is ground, always to the same sphere; and that they may be, therefore, perfectly true to each other, it is necessary to grind them with fine emery one against the other, laying them on a flat table for that purpose, and fixing one of them to the table. When the gages are perfectly true, let a piece of wood be turned about two tenths of an inch broader than the intended speculum, which it is best to cut in to one less than two tenths of an inch thick; and for specula of six, eight or ten inches broad, this should be at least three or four tenths thick when finished. This board being turned, take some common pewter, and mix with it about one tenth of regulus of antimony, and with that wooden pattern, call one of this pewter, which will be considerably harder than common pewter. Let this pewter pattern be truly turned in a lathe, and examined by means of the gages before mentioned, as a pattern for calling the specula themselves; and take care when it is turned, that it be at least one twentieth of an inch thicker, and about one tenth of an inch broader than the speculum intended to be cast from it. The manner of making the moulds for casting is now to be explained, and will serve for a direction as well for calling this pewter pattern, as afterwards for calling thereby the speculum itself. The flask should be of iron, and at least two inches wider every way than the speculum intended. In each flask there should be the thickness at least of one inch of sand. The calling sand which the common foundries use will answer the purpose as well as any; and any sand will do which is naturally mixed with a small proportion of clay, to make it stick. The sand should be as little wet as may be, and well beaten, but not too hard. The ingots should be cut so as to let the metal flow in, in four or five streams, over the whole upper part of the mould; otherwise, whatever pores happen in the metal will not be so equally dispersed as they should be over the whole face of the metal, these pores generally falling near the ingate streams. Let the flasks dry in the sun for some hours, or near a very gentle fire, otherwise they will warp, and give the speculum, when cast, a wrong figure: for, besides saving the trouble in grinding, it is best, on many accounts, to have the speculum cast of a true figure; and for this reason it is best to cast it from a hard pewter pattern, and not from a wooden one, as founders usually call.

For the composition of the metal and manner of casting it, see *Speculum*. When the metal is cast, the next business is to grind and polish it, for which, says Mr. Mudge, four tools are all that are necessary, viz. 1. The rough-grinder, for working all the rough face of the metal: this is best made of lead, stiffened with about a fifth or sixth part of tin; it should be at least a third more in diameter than the metal which is to be ground; and for one of any size, not less than an inch thick. It may be cemented on a block of wood, in order to raise it higher from the bench.

This leaden tool being cast, must be fixed in the lathe, and turned as true as possible by the gage to the figure of the intended speculum, making a hole in the middle, as a lodgment for the emery, of about an inch diameter for a metal of four inches: when this is done, deep grooves must be cut across its surface with a graver, in the manner represented in *Tab. II. Optic. fig. 25*: these grooves will serve to lodge the emery, and by this means the tool will cut much faster. Any kind of low handle, fixed on the back of the metal with soft cement, will be sufficient; but it should cover two thirds of its back to prevent its bending.

2. The next tool is the convex brass-grinder, on which the metal is to receive its spherical figure. In order to form this tool, procure a round stout piece of Hamburg brass, as much a sixth part larger than the metal to be polished; and let it be well hammered into a degree of convexity, by the assistance of the gage, suitable to the intended speculum; then scrape and clean the concave side so thoroughly, that it may be well tinned all over; then cast upon it, after it has been pressed a proper depth into the sand, the former composition of tin and lead in such a quantity, that it may, for a speculum of four inches

inches diameter, be at least an inch and a half thick, and with a half considerably broader than the top, in order that they may stand firmly upon the bench in the manner hereafter to be described. This being done, it must be fixed and turned in the lathe with great care, and of such a convexity as exactly to suit the concave gage. This tool must have a hole, somewhat less than that in the metal to be worked upon it, in the middle, quite through to the bottom. When it is finished off in the lathe, its diameter should be one eighth wider than the metal.

The 3d tool is the bed of hones, the use of which is to perfect the spherical figure, and to give the metal a fine smooth face. See *Bed of Hones*.

The 4th and last tool is the brailer, with which both the brass grinder and the hones are to be formed: this tool should be made of thick root brass, perfectly found, about a quarter of an inch thick, and hammered as near to the gage as possible; it should be then scraped, cleaned, and tinned on the convex side, as the second tool was on the concave, and the same thickness of lead and tin cast upon it. This should be as broad at bottom as at top; and when it is fixed in the lathe, and turned off concave to the convex gage with accuracy, the diameter ought to be of a middle size between the bones and the polisher or brass grinder, which is used for this purpose. Having with the lathe roughly formed the convex brass grinder, the bed of bones, and the concave brailer, the convex and concave brass tools and the metal must be wrought alternately and reciprocally upon each other with fine emery and water, so as to keep them to the same figure as nearly as possible, in order to which some washed emery must be procured, by putting it into a bottle, half filling the bottle with water, and shaking the mixture; so that the coardest of the emery will subside to the bottom first, and the finest remain at the top: when fresh emery is laid on the tools, it is best done by gently shaking the bottle, and pouring out a small quantity of the turbid mixture. The next operation is to grind the brass convex tool with the brailer upon it, which is continued for about a quarter of an hour, and then the convex tool is wrought upon the brailer in the same manner. When there have been wrought on each other, occasionally adding fresh emery, till the vestiges of the turning tool are got out and both brought nearly to a figure, the same form must be given to the metal, by grinding it upon the brass tool with the same kind of emery, taking care, however, by working the two former tools frequently together, to keep all three exactly in the same curve. The best kind of handle for the metal is made of lead, a little more than double its thickness, and somewhat less in diameter, of about three pounds weight, with a hole in the middle, a little larger than that in the metal: the handle should be cemented on with pitch. The upper edge of this weight must be rounded off, that the fingers may not be hurt, and a groove, about the size of the little finger, be turned round just below it, for the more conveniently holding and taking the metal off the tools. When the brailer, brass tool, and metal, are all brought to the same figure, and have a good surface, the next part of the process is to give a correct spherical figure and a fine face to the metal, upon the bones: these, however, should be covered with water for at least an hour before they are used, otherwise they will be liable to alter their figure; and they must be never suffered to grow dry whilst they are in use, for the same reason.

In order to give a proper figure to the bones, corresponding to that of the brass tool, brailer, and metal, when they are fixed down to the block, some common flour emery, unwashed, with a good deal of water must be put upon them, and the brailer being placed upon the bones, and rubbed over them with a few strokes and a light hand, the inequalities of the stone will be soon worn off, the mud that is generated being washed away, every quarter of a minute, with a great deal of water. As soon as the bones have received the general figure of the brailer, and all the turning strokes are worn out from them, the emery must be carefully washed off, and cleared from the joints with a brush under a stream of water. The brailer and metal must be likewise cleared in the same manner. The bones being fixed down to the block, the brailer must be worked upon them with very cautious, regular, short strokes, forward and backward, to the right and left, turning the axis of the brailer in the hand while you move round the bones, by shifting your position, and walking round the block. The manner of conducting this operation is minutely described by Mr. Mudge. The metal may then be rubbed upon the bones in the same cautious manner, occasionally rubbing the brailer upon the bones, in order to sharpen them. When in this way the hone-pavement has given

a fine face and true figure to the metal, you may proceed to try the metal and judge of its figure, by walking the hone-pavement quite clean; then putting the metal upon the centre of it, and giving two or three light strokes round and round only, without carrying the edges of the metal much over the bones; this will take out the order of straight strokes: then having again washed the bones, and placed the speculum upon their centre, with gentle pressure, slide it towards you till its edge be brought a little over that of the bones; then carry it quite across the diameter as far as the other side, and having given the metal a light stroke or two in this direction, take it off the tool. The metal being wiped quite dry, place it upon a table at a little distance from a window; stand as near the window, at some distance from the metal, and looking obliquely on its surface, turn it round its axis, and you will see, at every half turn the grain given by the last cross strokes fall upon your eye at once over the whole face of the metal. This is a certain proof of a true spherical figure.

The last operation is that of polishing the speculum, and this is the most difficult and essential part of the whole process. Mr. Mudge, having made some sacrifices on the method of Messrs. Hadley and Molyneux, generally followed, describes at large that which he has discovered, after a number of trials, both of giving a correct parabolic figure and an exquisite polish at the same time. Availing himself of the manner of polishing with pitch, practised by Sir Isaac Newton, and mentioned in his Optics, he formed his polisher by coating the brass convex tool equally with pitch, which should be neither very hard and resinous, nor too soft, about the thickness of a shilling, and by applying the brailer to it, gave the pitch upon the polisher a fine surface and the true form of the brailer. He then divided the leaden weight upon the back of the metal into eight parts, by strokes on the surface of the lead, which are marked with the numbers 1, 2, 3, 4, &c. in order to distinguish and regulate the turns of the metal. He also put half an ounce of putty into an ounce phial, and filled it two thirds with water; and having shaken the whole, let the putty subside, and stopped the bottle with a cork; the other appendages of his apparatus are a small-sized camel's hair brush in a tea-cup with a little water, a piece of dry clean soap in a galleypot, and a soft piece of sponge. These, as well as the metal, brailer, and polisher, should be constantly covered from dust.

The polisher being fixed down, is brushed over with the camel's hair brush, after it has been wetted and rubbed a little over the soap; then the brailer is worked lightly upon it, till it has acquired a good face and is fit for the metal. Then, having shaken up the putty in the phial, and touched the polisher in five or six places with the cork wetted with that and the water, the brailer is placed upon the tool, and a few strokes given to it upon the putty, in order to rub down any gritty particles: after which, having removed it, the metal is worked lightly upon the polisher, round and round, carrying the edges of the speculum, however, not quite half an inch over the edge of the tool, and now and then with a cross stroke. The putty is repeatedly applied in the same manner, and wrought into the pitch in the course of the operation; and if the brailer be apt to stick, and does not slide smoothly upon the pitch, the surface of either tool may be occasionally brushed over with the soap and water. After some continuance of this process, the pitch is well defended by the coating of the putty, and the metal, pressed only by its own weight and that of the handle, and occasionally moistened, moves over it with a more uniform and regular friction. When the polish of the metal nearly reaches the edge, the round strokes must be gradually altered for the short and straight ones. When this has been done for some time, in the manner minutely described by Mr. Mudge, the metal will begin to move freely as the friction increases, and the speculum polishes very beautifully and speedily, and the whole surface of the polishing tool will be equally covered over with a fine metallic bronze. As the metal wears much, its surface must be now and then cleaned; with a piece of flannel, leather, and the polisher likewise with a soft piece of wet sponge. You will now be able to judge of the perfect spherical figure of the metal and tool, when there is a perfect correspondence between the surfaces, by the fine equal feel there is in working, which is totally free from all jerks and inequalities. Having proceeded thus far, you may put the last finishing to this figure of the metal by bold cross strokes, only three or four in the direction of each of the eight diameters, turning the metal at the same time: this must be done quickly; for, if the tool be suffered to grow quite dry, you will never be able, with all your force, to separate that and the metal, without destroying the polisher by heat.

heat. The metal will now have a beautiful polish and a true spherical figure, but will by no means make a sharp distinct image in the telescope; for the speculum will not be found to make parallel rays converge without great aberration; and, indeed, the deviation will be so great, as to be very sensibly perceived by a great indistinctness in the image.

Supposing then the metal to be now truly spherical, stop the hole in the polisher, by forcing a cork into it underneath, about an inch, so that it do not reach quite to the surface; and having washed off any mud that may be on the surface of the tool with a wet soft piece of sponge, whilst the surface of it is a little moist, place the centre of the metal upon the middle of the polisher; then having, with the wet brush, lodged as much water round the edge of the metal as the projecting edge will hold, fill the hole of the metal and its handle with water, to prevent the evaporation of the moisture, and the consequent adhesion between the speculum and polisher, and let the whole rest in this state for two or three hours: this will produce an intimate contact between the two, and by parting with any degree of warmth they may have acquired by the warmth of the operation, they will become perfectly cold together. By this time you may push out the cork from the polisher to discharge the water, and give the metal the parabolic figure, in the following manner: move the metal gently and slowly at first, a very little round the centre of the polisher, then increasing by degrees the diameter of these strokes, and turning the metal frequently round its axis, give it a larger circular motion, without any pressure but its own weight: this manner of working may safely be continued about two minutes, moving yourself as usual round the block, and carrying the round strokes, in their increased and largest state, not more than will move the edge of the metal half an inch or five eighths over the tool. The speculum must not all this while be taken off from the polisher, and consequently no fresh putty can be added. It will not be safe to continue this motion longer than the time above mentioned; for if the parabolic tendency be carried in the least too far, it will be impossible to recover a true figure of that kind, but by going through the whole process for the spherical one in the manner before described, by the cross strokes upon the polisher, which takes a great deal of time.

In order to try the true figure of the speculum, place it in the telescope for which it is intended, and use the instrument as a kind of microscope, moving the object to such a distance that the rays may be nearly parallel. At about twenty yards a watch-paper, or some such object, on which there are some very fine hair-strokes of a graver, is fixed up. The lead must be taken off from the speculum, the speculum placed on the cell of the tube, and the instrument directed to the object; make an annular kind of diaphragm with card-paper, so as to cover a circular portion of the middle part of the metal between the hole and the circumference, equal in breadth to about an eighth part of the diameter of the speculum: this paper ring should be fixed in the mouth of the telescope, and remain so during the whole experiment, for the part of the metal covered by it is supposed to be perfect, and therefore uncovered.

There must likewise be two other circular pieces of card-paper cut out, of such sizes, that one may cover the centre of the metal by completely filling the hole in the last described annular piece; and the other, such a round piece as shall exactly fit into the tube, and so broad as that the inner edge may just touch the outward circumference of the middle annular piece. It would be convenient to have these two last pieces to be fixed to an axis, that they may be put in their places, or removed from thence so easily as not to displace or shake the instrument. All these pieces therefore together will completely shut up the mouth of the telescope.

Let the round piece which covers the centre of the metal, or that which has no hole in it, be removed; and, by a nice adjustment of the screw, let the image (which is now formed by the centre of the mirror) be made as sharp and distinct as possible. This being done, every thing else remaining at rest, replace the central piece, and remove the outside annular one, by which means the circumference only of the speculum will be exposed, and the image now formed will be from the rays reflected from the outside of the metal. If there be no occasion to move the screw and little metal, and the two images formed by these two portions of the metal be perfectly sharp and equally distinct, the speculum is perfect, and of the true parabolic curve; or at least the errors of the great and little speculum, if there be any, are corrected by each other.

If, on the contrary, under the last circumstance, the image from the outside of the metal should not be distinct,

and it should become necessary, in order to make it so, that the little speculum be brought nearer, it is plain that the metal is not yet brought to the parabolic figure; but if, on the other hand, in order to procure distinctness, you be obliged to move the little speculum farther off, then the figure of the great speculum has been carried beyond the parabolic, and hath assumed an hyperbolic form. When the latter is the case, the circular figure of the metal must be recovered (after having fixed on the handle with soft pitch) by bold, cross strokes upon the polisher, finishing it again in the manner above described. If the speculum be not yet brought to the parabolic form, it must cautiously have a few more round strokes upon the polisher; indeed a very few of them, in the manner before described, make in effect a greater difference in the speculum than would be at first imagined. If a metal of a true spherical figure were to be tried in the above mentioned manner in the telescope (which Mr. Mudge has frequently done), the difference of the foci of the two segments of the metal would be so considerable, as to require two or three turns of the screw to adjust them; so very great is the aberration of a spherical figure of the speculum, and so improper to procure that sharpness and precision necessary to a good reflecting telescope.

Supposing that the two foci of the different parts of the metal perfectly coincide, and that, by the union of them when the apertures are removed, the telescope shews the objects very sharp and distinct, you are not however then to conclude that the instrument is not capable of farther improvement; for you will perceive a sensible difference in the sharpness of the image, under different positions of the great speculum with respect to the little one, by turning round the great metal in its cell, and opposing different parts of it to different parts of the little metal, correcting by this means the error of one by the other. This attempt should be persevered in for some time, turning round the great speculum about one sixteenth at a time, and carefully observing the most distinct situation each time the eye-piece is screwed on: when, by trying and turning the great metal all round, the distinct position is discovered, the upper part of the metal should be marked with a black stroke, in order that it may always be lodged in the cell in the same position. This is the method Mr. Short always used; and the caution is of so much consequence, that he thought it necessary to mention it very particularly in his printed directions for the use of the instrument.

And farther, Mr. Short frequently corrected the errors of the great by the little metal in another way. If the great speculum did not answer quite well in the telescope, he cured that defect sometimes by trying the effect of several metals successively, by this means correcting the errors of one by the other.

The apparatus above described for examining the parabolic figure of the speculum, is represented in *Tab. II. Opticæ, fig. 26*. AA is the mouth of the telescope, or edge of the great tube; BB is a thin piece of wood fastened into and flush with the end of the tube, to which is permanently fixed the annular piece of pasteboard CC, intended to cover and to prevent the action of the corresponding part of the speculum. D is another piece of pasteboard, fixed by a pin to the piece of wood BB, on which it turns as on a centre; so that the great annular opening HH may be shut up by the ring FF, or the aperture GG by the imperforate piece E, in such manner that, in the first instance, the reflection may be from the centre, and in the latter, from the circumference of the great speculum.

Mr. Mudge has remarked, that the operation of polishing will not proceed well in the heat of summer or the cold of winter; and that neither this, nor the other of grinding upon the bones, will go on so well, unless they be continued uninterruptedly from beginning to end. In the above account it has been supposed, that the metal to be wrought was about four inches diameter; if it be either larger or smaller, the sizes of the bones, bruiers, and polisher, must be proportionally different.

The process for polishing the little speculum of a telescope, must be conducted in the manner already described for that of the large one; only observing, that as the little metal has an uninterrupted face, without a hole, so there is no occasion for one in the polisher; and likewise that, as the spherical figure is the only object in this case to be attempted, the difficulty of execution is much less than in the former, as it is always necessary to solder to the back of the little speculum a piece of brass, as a fixture for the screw to adjust its axis; Mr. Mudge has communicated a neat and safe method of doing it, which he received from the late Mr. Jackson, and which may be very useful to the optical or mathematical instrument-maker upon other occasions. Having cleaned the parts

parts to be folded very well, cut out a piece of tin-foil the exact size of them; then slip a feather into a pretty strong solution of sal ammoniac in water, and rub it over the surfaces to be folded; after which place the tin-foil between them as fast as you can (for the air will quickly corrode their surfaces so as to prevent the solder taking), and give the whole a gradual and sufficient heat to melt the tin. If the joints to be folded have been made very flat, they will not be thicker than a hair: though the surfaces be ever so extensive, the folding may be conducted in the same manner, only that care must be taken, by general pressure, to keep them close together. In this manner, for instance, a silver graduated plate may be soldered on to the brass limb of a quadrant, so as not to be discernible by any thing but the different colour of the metals.

We shall close this article with observing, that a method of giving the parabolic figure to his great speculum was a point of perfection which Gregory and Newton had wished for, but debarred of attaining, and which Hadley does not appear to have attempted either in his Newtonian or Gregorian telescope. Mr. Short is said to have possessed the secret; however it died with that ingenious artist. The method discovered by Mr. Mudge, above recited, is, as he has strong reasons to believe, the same with that of Mr. Short. See farther on this subject Smith's Optics, book iii. chap. ii. and Mr. Mudge's excellent paper in the Phil. Trans. vol. lxxv. part i. art. 16. p. 256-348. See TELESCOPE.

GRINDING is also used for a coarser and less accurate method of smoothing or polishing the surface of a body, particularly glass for looking-glasses, &c.

In the new method of working large plates of glass for looking-glasses, coach-glasses, &c. by moulding, and, as it were, casting them, somewhat after the manner of metals, described under the article GLASS, the surface being left uneven, it remains to be ground and polished. In order to this, the plate of glass is laid horizontally on a floor in manner of a table, and to secure it the latter is plastered down with mortar or stucco, that the effort of the workman, or of the machine used therein, may not shake or displace it: so fasten it there is a strong wooden frame that surrounds it an inch or two higher than the glass: the bottom or base of the grinding engine is another rough glass, about half the dimensions of the former: on this is a wooden plank, cemented thereto, and upon this are proper weights applied, to promote the friction, the plank or table being fastened to a wheel, which gives it motion. This wheel, which is at least five or six inches diameter, is made of a very hard but light wood, and is wrought by two workmen placed against each other, who push and pull it alternately; and sometimes, when the work requires it, they turn it round. By such means, a constant mutual attrition is produced between the two glasses, which is favoured by water and sands of several kinds bellowed between; sand still finer and finer being applied, as the grinding is more advanced: at last emery is used. We need not add, that as the upper or incumbent glass polishes and grows smoother, it must be shifted from time to time, and others put in its place.

It is to be noted, that only the largest size glasses are thus ground with a mill; for the moulding and smaller sorts are wrought by the hand; to which end there are four wooden handles at the four corners of the upper floor or carriage, for the workmen to take hold of, and give it motion. What remains to the perfection of glass comes under the denomination of polishing.

GRINDERS, *molari dentis*. See MOLARS.

GRINETTA, in Ornithology, the name of a water fowl of the gallinula or moor-hen kind, having open feet, and no imbricæ annexed to them. This is the *galinula porzana* in the Linnæan system. It is smaller than the moor-hen and the water-rail. Its legs are of a dusky greenish colour, and its toes very long; its beak very short, compressed sideways, and pointed at the end, and is covered at the origin with a deep yellow substance, looking like a plaster put on it. The head is brown, spotted with black; the neck a deep olive, spotted with white; from the bill, beyond the eyes, is a broad grey bar; the feathers of the back are black next their shafts, then olive-coloured and edged with white; the scapulars are olive, finely marked with two small white spots on each web. It is common in Italy and Germany, but not so frequent in England, where it is said to be migratory. It inhabits the sides of small streams, concealing itself among the bushes. Its usual weight is about four ounces five drams.

GRIPE, or *Grippe*, in Husbandry, is a small ditch cut across a meadow, or ploughed land, in order to drain it. It also signifies a handful; as, a gripe of corn.

GRIPE, in Medicine. See CRANE.

GRIPE of a ship, is the compass or sharpness of her stem under water, chiefly towards the bottom of her stem.

The design of shaping her so, is, to make her gripe the more, or keep a good wind; for which purpose, sometimes a false stem is put on upon the true one.

GRIPE is also a sea-phalse for a ship's being apt to run too much to windward of her course, particularly when the sails with the wind on her beam or quarter: this effect is partly occasioned by the shock of the waves that strike the ship perpetually on the weather-quarter, and force the stem to leeward; but principally by the arrangement of the sails, which disposes the ship continually to edge to windward, while in this situation of sailing: in such case they lay the gripe.

GRIPES, *termina ventris*, in Medicine, a sort of colic, or painful disorder of the lower belly, occasioned by some sharp pungent matters vellicating the parts, or by wind pent up in the intestines. See COLIC and DYSENTERY.

The gripe is a very common symptom in young children, and may be caused by the aliment they use, which is considerably different from what they had been accustomed to in the uterus.

The retention of a part of the meconium may also give occasion hereto, as being somewhat acrimonious.

This disorder sometimes proves so violent, as to throw the child into universal convulsions, or to cause, what is vulgarly called *convulsions of the bowels*.

GRIPES, or **COLIC**, in Farriery, is an acute disease, to which horses are very often subject. There are three different species of this disorder, viz. the flatulent or windy, the bilious or inflammatory, and the dry gripe. The first is known by the horse's alternately and suddenly lying down and rising; by his striking his belly with his fore feet, stamping with his fore feet, and refusing his meat; and when the gripe is violent, by convulsive twitches, turning up his eyes, stretching out his limbs, and alternate sweats and cold damps; striving to rise, turning his head frequently to his flanks, rolling about, and often turning on his back. The confined wind may be discharged by emptying the rectum with a small hand dipped in oil, and tugs the neck of the bladder is eased of its load, and the horse flukes. It is always proper to bleed young and plethoric horses in the neck-vein. The following ball and clyster seldom fail of giving relief: take Stralburgh or Venice turpentine, and powdered juniper berries, of each half an ounce; sal prunella, or salpetre, an ounce; oil of juniper one dram; salt of tartar two drams, make these ingredients into a ball with any syrup; and give it whole, waiting it down with a decoction of juniper-berries, or a horn or two of ale. If this ball does not succeed, and make the horse break wind and fluke plentifully, in an hour or two give him another ball, and add to it a dram of salt of amber; and this may be repeated a third time, if necessary: during the fit, let the horse have gentle exercise. Let the following clyster be given between the balls, or alone, and repeated occasionally: take chamomile flowers two handfuls; snife, corianders, and fennel seeds, of each an ounce; long pepper half an ounce; boil them in three quarts of water to two; and add Daisy's elixir, or gin, half a pint; oil of amber, half an ounce, and oil of chamomile eight ounces. The horse should be well rubbed, clothed, and littered with clean straw up to his belly: and a pint of brandy, rum, or Geneva, with as much sweet oil, may be given for a drink; and if this should not succeed, boil an ounce of pepper or ginger in a quart of milk, and add to it a handful of salt, and half a pint of oil, which, given warm, will purge in two or three hours.

The bilious inflammatory gripe is attended with a fever, besides more of the preceding symptoms: the horse also generally throws out a little loose dung, with ho scalding water, the blackish or reddish colour and fetid smell of which denote an approaching mortification. In this case three quarts of blood should be immediately taken away, and the bleeding should be repeated, unless the symptoms abate in a few hours. The emollient clyster, with two ounces of nitre dissolved in it, should be thrown up twice a day, and gum Arabic water should be plentifully drank, and a pint of the following mixture should be given every two or three hours, till favourable loose stools are procured, and then only night and morning, till the disorder is removed. Take fenna, three ounces, and salt of tartar half an ounce; infuse them for an hour or two in a quart of boiling water, and add two ounces of lenitive electary, and four of Glauber salts. If the disorder increases, recourse must be had to the jesuit's bark, which should be given in the decoction to the quantity of a pint every three hours, with a gill of red Port wine. In a case of less consequence, take diacenta, one ounce; diacordium, half an ounce; powder

ed myrrh two drams; make these into a ball with two drams of oil of amber, and give it twice or thrice a day.

The dry *gripes* arise often from costiveness, and are discovered by the hard frequent and fruitless motion to dung, the blackness and hardness of the dung, the frequent and quick motion of his tail, the high colour of his urine, and his great restlessness. The fruit *gripes* should, in this case, be relieved by an oilied hand; then throw up the following emollient cyfter twice a day: take marshmallows and chamomile flowers, of each a large handful; bruise bay-berries and fennel seeds, of each an ounce; boil them in a gallon of water to three quarts; and having poured the liquor into a pan, dissolve in it half a pound of treacle, and a pint of linseed, or of any common oil. The purging drink prescribed for the infant *gripes* should be also given, till the symptoms are removed. The diet for a horse with the *gripes* should be folded down, warm water-gruel, or water prepared by dissolving four ounces of gum Arabic in a quart of water, and mixing it with other water. Farmer's Dict. art. *Gripes*.

GRIPER, in *Sea Language*, is the name of a machine formed by an assemblage of ropes, blocks, and dead-eyes, and used to secure the boats upon the deck of a ship at sea, and prevent them from being shaken by the labouring of the vessel. The blocks, which are fastened at their ends, are fixed in ring-bolts in the deck on each side of the boat; whence, passing over her middle and extremities, they are extended, by means of the dead-eyes, so as to render the boats firm and secure.

GRISLAGINE, in *Ichthyology*, the name of a fresh-water fish, of the cyprinæ kind, with whitish fins, and eleven rays in the anal fin, common in the rivers of Germany. Its something approaches to the common roach in shape. Its back is of a dusky blue, and its belly and sides, below the side-lines, are of a silvery whiteness. The side-lines are yellow and dotted, and over these there is an interrupted blackish line running into several oblong streaks from the gills to the tail.

GRISLEA, in *Botany*, a genus of the *pentandria monogynia* class; the characters of which are these: the perianth consists of one leaf, and is of a tubulated bell-shaped form; it stands erect, and is divided into four segments at the end; the flower consists of four oval petals, extremely small, scarcely indeed exceeding in size the segments of the cup from which they arise; the stamina are eight, subulate, erect, and extremely long filaments; the anthers are simple and erect; the germen of the pistil is oval; the style is capillary, and of the length of the stamina; the stigma is simple; the fruit is a globose, single-celled, polyspermous capsule. It is an American tree, extremely well distinguished from all others by the flower alone.

GRISLY *fish*, among *Herbalists*, denote thin, flat, scaly fish.

GRISOLA, in *Ornithology*, the name of a bird of the lark kind, described by Aldrovandus, and supposed by Mr. Ray to be the same with the *strolatita*, or *terdus*, of the Venetians.

GRIST, denotes corn ground, or ready for grinding.

GRIZZLE, is sometimes used for **GREY**.

GRITHBRECHIE, in our *Old Writers*, the same with *breach of the peace*. In this sense we find it mentioned in Leg. Hen. I. cap. 36. *In casu regis grithbreche 100 sili. amandabit.*

It comes from the Saxon, *grythwite*, which signifies the same.

GRITHSTOLE, in our *Old Writers*, a place of sanctuary.

Blount. See **FRIDSTOLE**.

GRITS, in *Natural History*. See **SABURRA**.

GRIT-TIER, is a stone consisting of particles of sand agglutinated together. Of this kind of stone there are many varieties, differing in the size of the particles of sand that compose them, the different properties of these sands, and their different degrees of compactness and agglutination. Some of these stones are used for building, others for grinding, others for whetting sharp steel instruments, and others for filtering water. See **FILTARE**, **GRINDING**, **WHETTING**, and **STONE**.

GROANING, in *Medicine*, a term used for the cry or noise of a sick.

GROAT, an English money of account, equal to four pence.

Other nations, as the Dutch, Polanders, Saxons, Bohemians, French, &c. have likewise their *groats*, groots, groebers, gros, &c.

We had no silver money in the Saxon times bigger than a penny; nor after the Conquest, till Edward III. who about the year 1351. coined groats, i. e. *groati*, or great pieces which went for 4d. a-piece, and half-groats; and so the matter stood till the reign of Henry VIII. who, in 1505, first coined shillings.

GROATS, a term used in many parts of the kingdom for called oats, or oats only half-ground.

GROGERS, by the Stat. 37 Edward II. cap. 5. is used for those who engross merchandize. See **ENGROSSING**.

But *grogers* are now those who deal in *grog*, (spice), &c. and form one of the incorporated companies of London. See **COMPANY**.

GROGRAM, in the *Manufacture*, a sort of stuff, made of silk and mohair, being in reality no more than a taffety, coarser and thicker than ordinary.

GROIN, in *Anatomy*. See **INGUEN**.

GROMA, among the *Romans*, a way-wiler, or surveying instrument; whence *Gromæ* who used it were called *gromatæ*, and the place in the camp where it was kept, *groma*. *Enrico*.

GROMMETS, in a *Ship*, are small wreaths, formed of a strand of rope, and used to fasten the upper edge of a flap-sail to its respective stay, in different places. By means of the *grommets* the sail is accordingly hoisted or lowered. Instead of these *hanks* have been lately introduced.

GROMPHENA, in *Botany, a name used by some authors, particularly by Pung, for the common garden MARY-GOLD.*

GROMWELL, or **GROMILL**, in *Botany, *Subspernum*, a genus of the *pentandria monogynia* class. Its characters are these: the flower hath a permanent empalement, cut into five parts; and one petal, with a cylindrical tube, divided into five obtuse points at the brim; the chaps are pedate; it has five short stamina, which are fast up in the chaps of the petal; and hath four germina, which turn to no many oval, hard, smooth, acute-pointed seeds, sitting in the spreading empalement. Miller reckons five species, and Linnaeus seven. The seeds of the greater upright *gromwell* have been accounted powerfully diuretic, and cleansers of the reins and waters, being boiled in wine or water; and of great service against the stone, gravel, or stoppage of urine, as also against the heat of it, and a gonorrhoea. Mathiolus commends two drams of the powder, to be given in women's milk, as a speedy help in hard labour. But they have long been discarded from practice. The root of the hairy *gromwell*, or *alsant*, with smaller flowers, and all unctuous substances, and to rectified spirit of wine. Its chief use is for colouring oils, plasters, lip-salves, &c. See **ARCHURA**.*

GRONDEUR, a name given by the French in America to a fish which is commonly eaten there; the jaws of which have been brought into Europe, and being examined by Mr. Jussieu, were found to be in a remarkable manner with teeth, which perfectly resembled the human, called *crapaudus*, and by some *serpentinus*; and which, in their fossil state, had been for many ages accounted gemæ. The arrangement of these teeth is such, that the whole flat surfaces of the upper and lower jaw are in a manner paved with them. They are of different shape and size in the different parts; those placed towards the edges were of the small and flat kind, commonly found in Malta, and called *serpenti-teeth*; and the larger *two-jawed*, as they are called, were placed more toward the middle; the largest of all being placed in two straight rows, or lines, along the center of each jaw. Each of these teeth is articulated by a gomphosis in the jaw, and when taken out, they all have that natural cavity which is found in the hinder part of the fossil ones. The sockets of these teeth have much the appearance of those from whence teeth have been frequently changed, and probably the fish sheds them often in the course of its life. *Mem. Acad. Par. 1723.*

GRONNA, in our *Old Writers, a deep pit, or bituminous place, where turfs are dug for burning.*

GRONOVIA, in *Botany, a genus of the *pentandria monogynia* class, the characters of which are: that the flower hath a single-lobed coloured empalement, cut into five parts; five small petals; and five hairy stamina, inserted alternately in the empalement; the germen becomes a roundish coloured fruit, with one cell, inclosing one large roundish seed. There is only one species, first discovered by Dr. Houftoun at La Vera Cruz.*

GROOM, denotes a servant in some inferior post. In which sense it amounts to the same with the old word, *gards*, and the French *garçon*.

The word is formed from the Flemish, *grom*, *paer*, a boy. *Groom* is the denomination of several officers and servants of the king's household.

There are *grooms* of the almontry, *grooms* of the compting-house, *grooms* of the great-chamber, the privy-chamber, and the bed-chamber, *grooms* of the robes, of the wardrobe, &c.

GROOM of the stable. See **STABLE**.

GROOM porter is an officer of the household, whose business

nets is to see the king's lodging furnished with tables, chairs, stools, and bring: as also to provide cards, dice, &c. and to decide disputes arising at cards, dice, bowling, &c.

GROG is more particularly used for a servant, appointed to attend on horses in the stables. See *KNIGHT*.

GROOVE, or GROVE, among *Joiners*, denotes the channel that is made by their plough in the edge of a moulding, stile, or rail.

GROOVE also denotes a gardener's tool for transplanting flowers.

GROOVE, in *Mining*, is the shaft, or passage into the lead-mine, by which they draw up their ore. They are sometimes sunk in the vein, and sometimes out.

GROOZDISHYS, in *Botany*, a name given by the Russians to a species of mushroom resembling our pepper, or milky-mushroom, described by Lister, Ray, &c. but larger. The *groozdys* is very broad and thick, and abounding with an acid juice. The Russians prefer them in pickle, and eat them with their meats. When eaten fresh they inflame the mouth and throat, and endanger suffocation. Phil. Trans. N° 89.

GROS, a foreign money, in divers countries, answering to our *grat*.

A pound *grat*, livre de *grat*. See POUND and LIVRE.

GROSS, or GROSSUS, in our *Antient Law Writers*, denotes a thing absolute, and not depending on another. Thus *vilain in gross*, *vilainus in gross*, was a servant, who did not belong to the land, but immediately to the person of the lord; or a fertile person not appendant, or annexed, to the land or manor, and so go along with the tenures as appurtenant to it; but, like other personal goods and chattels of his lord, at his lord's pleasure and disposal.

GROSS, *acrostichum*. See *ANDROMED*.

GROSS-BEAM, in *Astronomy*, a name by which we commonly call the COCCOTIAURUS, called also at other times the *horn-jaw*. This is the *LORIS coocotiauraster* in the Linnean system.

GROSS, in *commerce*. See *COMMON*.

GROSS weight, is the weight of merchandizes, and goods, with their dunt and dross, as also of the bag, case, chest, &c. wherein they are contained; out of which *gross* weight, allowance is to be made of tare and tret.

GROSS average. See *AVERAGE*.

GROSS is also used for the quantity of twelve dozen.

GROSSA, a *grout*. *Grossus est rogi* was *grossa*, *que tenent quatuor denarii, de quolibet vira et muliere*. Knighton, 30. 1378.

GROSSE-LEW, in our *Antient Law Books*, signifies such wood as has been, or is, either by the common-law, or custom of the country, reputed timber.

GROSSULARIA, or RIBES. See *GOOSEBERRY*.

GROTESQUE, GROTESCO, or GROTTESQUE, a wild whimsical figure, or design of a painter, or engraver; having in it something ridiculous, extravagant, and even monstrous. The name arises hence, that figures of this kind were anciently much used to adorn the grottoes wherein the tombs of eminent persons, or families, were inclosed. Such was that of Ovid, whose grotto was discovered near Rome about one hundred years ago.

Calot, a celebrated engraver of Lorraine, had a wonderful genius for designing *grotesques*: the like is said of Leonardo da Vinci.

We also extend the word *grotesque* to any thing whimsical, or wildly pleasant, in a person's dress, discourse, &c. *Masquerade habits* are the more valued, the more *grotesque* they are.

Our theatres present us with entertainments in *grotesque* characters, i. e. persons quaintly dressed; as Harlequins, Scaramouches, &c. Pliniodas has given us a very *grotesque* picture of *Æolus*. Aristotle and the Italian poets are full of *grotesque* descriptions.

GROTESQUE-work, GROTESCO-work, or GROTTESCO, denotes a work, or composition, in painting and sculpture, in the *grotesque* manner, or taste; consisting either of things which are merely imaginary, and have no existence in nature, or of things turned and distorted out of the way of nature, so as to raise surprise and ridicule. *Grotesque-work* is much the same with what we sometimes also call *antique* and *monstrous*.

GROTESQUES, or GROTTESQUES, are particularly used for little fanciful ornaments, of animals, compounded with foliage, fruit, &c.

Such are those painted by Raphael in the apartments of the Vatican, and those carved by Michael Angelo in the ceilings of the Porch in the Capitol. Vitruvius calls compartments of this kind *hermaphrodites*.

GROTTO, or GROTTOA, in *Natural History*, a large deep cavern, or den, in a mountain or rock.

The word is Italian, *grotta*, formed, according to Menage, &c. from the Latin *crypta*: Du-Cange observes, that *grotta* was used in the same sense in the corrupt Latin.

The ancient anchorites retired into dens, and *grottoes*, to apply themselves the more strictly to meditation.

Okey-hole, Elden-hole, Pool's-hole, and the Devil's-A-se in the Peale, are famous among the natural caverns or *grottoes* of our country.

The entrance of Okey-hole, on the fourth mile of Mendips-hill, is in the fall of those hills, which is but all about with rocks, and has near it a precipitate descent of near twelve fathoms deep, at the bottom of which there continually issues from the rocks a considerable current of water. The naked rocks above the entrance show themselves about thirty fathoms high, and the whole ascent of the hill above is about a mile, and is very steep. As you pass into this vault, you go at first upon a level, but advancing farther, the way is found to be rocky and uneven, sometimes ascending and sometimes descending. The roof of this cavern, in the highest part, is about eight fathoms from the ground, but in many particular places it is so low, that a man must stoop to get along. The breadth is not less various than the height, for in some it is five or six fathoms wide, and in others not more than one or two: it extends itself in length about two hundred yards. People talk much of certain floors in it, resembling men and women, and other things, but there is little matter of curiosity in these, being only shapeless lumps of common spar. At the farthest part of the cavern there is a good stream of water, large enough to drive a mill, which passes all along one side of the cavern, and at length flows down about six or eight fathoms, among the rocks, and then pressing through the clefts of them, discharges itself into the valley.

The river within the cavern is well stored with eels, and has some trout in it; and these cannot have come from without, there being no great fall near the entrance. In dry summers, a great number of locusts are seen all along this cavern, even to the farthest part of it; and on the roof of it, at certain places, hang vast numbers of bats, as they do in almost all caverns, the entrance of which is either level, or but slightly ascending or descending; and even in the more perpendicular ones they are sometimes found, provided they are not too narrow, and are sufficiently high. The cattle that feed in the pastures, through which this river runs, have been known to die suddenly sometimes after a flood; this is probably owing to the waters having been impregnated, either naturally or accidentally, with lead-ore. Philosoph. Observ. N° 2. p. 2.

In the Philosophical Transactions, N° 480. p. 223, we have an account of a subterranean *grotto*, or cavern, near Werdale, about twenty miles south-west of Newcastle.

Elden-hole is a huge profound perpendicular chasm, three miles from Buxton, ranked among the natural wonders of the Peak. Its depth is unknown, and is pretended to be unfathomable. Cosson tells us he found 283 yards; yet the plummet still drew. But he might easily be deceived, unless his plummet was very heavy; the weight of a rope of that length might well make the landing of the plummet scarce perceivable. Phil. Trans. N° 407. p. 24.

Peake's-hole, and Pool's-hole, called also the Devil's-A-se, are two remarkable horizontal springs under mountains; the one near Caisleton, the other just by Buxton. They seem to have owed their origin to the springs which have their current through them; when the water had forced its way through the horizontal fissures of the strata, and had carried the loose earth away with it, the loose stones must fall down of course; and where the strata had few or no fissures, they remained entire, and so formed there very irregular arches, which are now so much wondered at. The water which passes through Pool's-hole is impregnated with particles of limestone, and has incruited the whole cavern in such a manner that it appears as one solid rock. Martyn, in Phil. Trans. N° 407. p. 27. & seq.

In *grottoes* are frequently found crystals of the rock, flint-stones, and other natural conglaciations, and those often of an amazing beauty.

M. Homberg conjectures, from several circumstances, that the marble pillars of the *grotto* of Antiparos vegetate, or grow. That author looks on this *grotto* as a garden, whereof the pieces of marble are the plants; and endeavours to shew, that they could only be produced by some vegetative principle. Mem. Acad. anno 1702.

At Polignus in Italy, is another *grotto*, consisting of pillars and orders of architecture of marble, with their ornaments, &c. scarcely inferior to those of art; but they all grow downwards: so that if this too be a garden, the plants are turned upside down. Mem. de l'Acad. anno 1711.

The Zirehnitzner sea, or lake, in Carniola, famous for being full of water, fish, &c. the best part of the year,

and quite dry, and bearing grass, corn, &c. the rest proceeds from some subterraneous *gratto*, or lake; as it is made highly probable by Mr. Vavilor, Phil. Trans. N° 191.

We have several *gratto* famous in natural history: as, *Grotto del Coni*, a little cavern near Pozzuoli, four leagues from Naples, the streams whereof are of a medicinal or noxious quality; whence also, it is called *laca tempesta*, the poisonous mouth. See *MARINUS*. Two miles from Naples, says Dr. Mead, just by the Lago de Agnano, is a celebrated *gratto*, commonly called *la Grotta del Coni*, and equally destructive to all within the reach of its vapours.

It is a small *gratto* about eight feet high, twelve long, and six broad; from the ground arises a thin, subtle, warm fume, visible on-ly to a discerning eye, which does not spring up in little parcels here and there, but in one continued stream, covering the whole surface of the bottom of the cave; having this remarkable difference from common vapours, that it does not, like smoke, disperse itself into the air, but quickly after its rise, falls back again, and returns to the earth: the colour of the fibres of the *gratto* being the measure of its ascent; for so far is it of a darkish-green, but higher only common earth. And as I myself found no inconvenience by standing in it, so no animal, if its head be above this mark, is the least injured. But when, as the manner is, a dog, or any other creature, is forcibly kept below it; or, by reason of its smallness, cannot hold its head above it; it presently loses all motion, falls down as dead, or in a swoon; the limbs convulsed and trembling, till at last no more signs of life appear than a very weak and almost insensible beating of the heart and arteries; which, if the animal be left a little longer, quickly ceases too, and then the case is irrecoverable; but if it be fetched out, and laid in the open air, it soon comes to life again, and sooner, if thrown into the adjacent lake.

The fumes of the *gratto*, the same author argues, are no real poison, but act chiefly by their gravity; else the creatures could not recover to food; or, if they did, some symptoms, as faintness, &c. would be the consequence of it. He adds, that in creatures killed therewith, when dissected, no marks of infection appear; and that the attack proceeds from a want of air, by which the circulation tends to an entire stoppage; and this so much the more, as the animal inhales a fluid of a quite different nature from the air, and so in no respect fit to supply its place.

Taking the animal out, while yet alive, and throwing it into the neighbouring lake, it recovers: this is owing to the coldness of the water, which promotes the contraction of the fibres, and so affords the retarded circulation; the small portion of air which remains in the vesicles, after every expiration, may be sufficient to drive out the noxious fluid. After the same manner, cold water acts in a delirious animal: the lake of Agnano has no greater virtue in it than others.

The true explanation of the noxious effects of this vapour may be seen under the articles *AIR*, and *Fixed AIR*, *DAMP*, &c.

Grotta del Serpi is a subterraneous cavern near the village of Saffa, eight miles from the city of Braccano in Italy, described by Kircher thus:

The *Grotta del Serpi* is big enough to hold two persons: it is perforated with several fissilar apertures, somewhat in manner of a sieve; out of which, at the beginning of the spring- season, issues a numerous brood of young snakes of divers colours, but all free of any particular poisonous quality.

In this cave they expose their lepers, paralytics, arthritics, and elephantiac patients, quite naked; where the warmth of the subterraneous streams resolving them into sweat, and the serpents belonging variously all around, licking and sucking them, they become so thoroughly freed of all their vicious humours, that upon repeating the operation for some time, they become perfectly restored. This cave Kircher visited himself, and found it warm, and every way agreeable to the description given of it. He saw the holes, and heard a murmuring hissing noise in them. Though he missed seeing the serpents, it not being the season of their creeping out; yet he saw a great number of their exuvie, or sloughs, and an elm, growing hard by, laden with them.

The discovery of this cave was by the case of a leper going from Rome to some baths near this place; who losing his way, and being benighted, happened upon this cave; and finding it very warm, pulled off his cloaths; and being weary and sleepy, had the good fortune not to feel the serpents about him till they had wrought his cure. Museum Wormian.

The salutary effects of this cavern were probably of the

same nature, and to be ascribed to the same cause with those of the *PRAMONY* and *SPA* waters, abounding with a great quantity of the *GAS*, or *fixed AIR*, which lies aloft to a certain height on the surface of the ground; and whither diseased persons resort, and find relief in a variety of disorders. The antipeptic salutory quality of this air is now sufficiently known.

Milly Grotto, *Cypria Lactea*, a mile distant from the ancient village of Bethlehem, is said to have been thus denominated on occasion of the blessed Virgin, who let fall some drops of milk in giving suck to Jesus in this *gratto*. And hence it has been commonly supposed, that the earth of this cavern has the virtue of restoring milk to women that are grown dry, and even of curing fevers.

Accordingly, they are always digging in it, and the earth is sold at a good rate to such as have faith enough to give credit to the fable. An altar has been built on the place, and a church built by it.

Grotto is also used for a little artificial edifice made in a garden, in imitation of a natural *gratto*.

The outside of these *gratto* are usually adorned with rustic architecture, and their inside with shell work, fossils, &c. finished likewise with jets d'eau or fountains, &c.

A cement for artificial *gratto* may be made thus: take two parts of white rosin, melt it clear, and add to it four parts of bees wax; when melted together add two or three parts of the powder of the stone you design to cement, or so much as will give the cement the colour of the stone; to this add one part of floor of sulphur: incorporate all together over a gentle fire, and afterwards knead them with your hands in warm water. With this cement the stones, shells, &c. after being well dried before the fire, may be cemented.

Artificial coral branches, for the embellishment of *gratto*, may be made in the following manner: take clear rosin, dissolve it in a brass-pan; to every ounce of which add two drams of the finest vermilion: when you have stirred them well together, and have chosen your twigs and branches, peeled and dried, take a pencil and paint the branches all over with the composition in warm; afterwards shape them in imitation of natural coral. This done, hold the branches over a gentle coal-fire, till all is smooth and even as if polished.

In the same manner white coral may be prepared with white lead, and black coral with lamp-black.

A *gratto* may be built with little expence, of glass, cinders, pebbles, pieces of large flint, shells, mors, stones, counterfeit coral, pieces of chalk, &c. all bound or cemented together with the above described cement.

The *gratto* at Versailles is an excellent piece of building. Solomon de Caux has an express treatise of *gratto* and fountains.

GROVE, in Gardening, &c. a small thick wood, impervious to the rays of the sun.

The ancient Romans had a sort of *grove* near several of their temples, which were consecrated to some god, and called *lur*, by antiphrasis, *non lucendi*, as being shady and dark.

Groves are not only great ornaments to gardens, but also afford relief against the violent heats of the sun: furnishing shade to walk under in the hottest parts of the day, when the other parts of the garden are intolerable: so that every garden must be defective which has no shade. *Groves* are of two sorts, either open or close. Open *groves* are such as have large shady trees, which stand at such distances, as that their branches approach near enough to each other, to prevent the rays of the sun from penetrating through them.

Most of the *groves* that have been planted, either in England or in the celebrated gardens of France, are only a few regular lines of trees; many of which are avenues to the habitation, or lead to some building or other object: but those do not appear so grand as others that have been made in woods, where the trees have grown at irregular distances, where they have large spreading heads, and are left so far asunder as to permit the grass to grow under them. For nothing is more noble than fine spreading trees, with large stems growing through the grass: especially if the grass is well kept, and has a good verdure. Besides, most planted *groves* have a gravel walk made in a straight line between them, which is offensive to true taste: therefore whenever a gravel walk is to be carried through *groves*, it will be much better to twist it about, humouring the disposition of the trees, than to attempt regularity. But under large trees, dry walks are not so useful as in open places; because after rain the dropping of the trees will for some time render the walks useless.

In planting *groves*, the trees should be disposed irregularly, which will give them a more noble appearance, and

also form a shade sooner than when they are planted in lines. When in planting a garden, full grown trees are found upon the spot, they should, if possible, remain inviolate; for it will be better to put up with many inconveniences than to destroy what will require an age to supply.

Cloister *groves* have frequently large trees standing in them, but the ground under them filled with shrubs or underwood; so that the walks within them are private, and screened from winds, by which means they are rendered agreeable for walking, at such times when the air is either too hot or too cold for walking in the more exposed parts of the garden. They are often so contrived as to bound the open groves, and frequently to hide the walls or other inclosures of the garden; and when they are properly laid out with dry walks winding through them, and sweet-smelling shrubs and flowers irregularly planted at the sides, they have a charming effect. If they are continued round the whole inclosure of the garden, there will be a much greater extent of walks; and these shrubs will appear the best boundary, where there are not fine prospects to be gained. Miller.

Groves have been in all ages held in great veneration. The *PROPHETAS*, and high-places of the Jews, whither they resorted for the purposes of devotion, were probably situated in *groves*. See *JOSHUA* xiv. 26. The *prophetess* in Alexandria, mentioned by Philo, had *groves* about them, because he complains that the Alexandrians, in a tumult against the Jews, cut down the trees of their prophetess: that at Rome, in *Egeria's grove*, was of the same sort. The veneration which the ancient *PAIDNS* had for *groves* is well known.

GROUNDS, in *architecture*, is a piece of land, or soil; or a portion of earth, whether firm, or soft, to be filled, and cultivated.

All sorts of *grounds* may be reduced to boggy or marshy, chalky, gravelly, and stony. See *MARSH*, *CHALK*, *SAND*, *GRAVEL*, *SOIL*, &c.

GROUND-ANGEL. See *BATTLE-ANGEL*.

GROUND, battle. See *BATTLE*.

GROUND, among Bowlers. See *BOWLING*.

GROUND, breaking. See *BREAKING*.

GROUND, unmaking. See *COMMANDING*.

GROUND, in Eschion, denotes a varnish smeared over the surface of the metal to be etched, to prevent the aqua fortis from eating, or having effect, except in places where this *ground* is cut through, or pared off, with the points of needles. See *ETCHING*.

GROUND-ivy, *glomera*, in *Botany*; called also *gill* *go* by the *grounds*, *alobus*, or *turn-bush*, is a genus of the *diogenia* *gynaphoraria* class; the anthers of which unite in form of a crot, and the calyx is divided into five segments; this is a plant that grows naturally under hedges and on the sides of banks in moist parts of England, and therefore it is rarely cultivated in gardens. The leaves which are rounded, or kidney-shaped, are set in pairs at the joints, on the bosoms of these come forth clusters of blue-labiated flowers, whose upper lip is cloven and turned backwards; this plant flowers from April almost to the end of summer, and is generally found green all the winter.

Ground-ivy is an aqueous and dissolvent, and famous, both externally and internally, as a vulnerary. It is much used by way of tea in disorders of the breast and lungs, and is sometimes an ingredient in the pectoral decoction. It is esteemed a specific in eruptions and ulcerations of the viscera, and particularly of the kidneys and lungs; with which intention its juice has been given to people in consumptions. Linnaeus praises it in an *em-pyema* and *venena pulmonum*, and recommends it to such as void blood and purulent matter by urine. It is also said to be good in bruises, and to cure the head-ach; but notwithstanding all this, it is left in great measure to the common people.

It gives the denomination to a sort of medicated ale, or drink, commonly called *gill*, or *gill-ale*, made by infusing the dried leaves of the plant therein.

The leaves of the common *ground-ivy* are found sometimes to produce on their under part certain galls, or round protuberances, of a fleshy texture, and green colour, of the size of nutmegs, or sometimes larger. These are in some years so common in France, that the poor people eat them either raw or roasted, and find them a wholesome food.

GROUND-LINE, in *Perspective*. See *TERRITORY LINE*.

GROUND, in the Munge. See *TERRAIN*.

GROUND, manuring. See *MANURING*.

GROUND-RICE. See *NICHU*.

GROUND-RICE. See *EARTH-RICE*.

GROUND, RICE. See *PALESTINE*.

GROUND-RICE. See *PALESTINE*.

GROUND, RICE. See *PALESTINE*.

GROUND, RICE. See *PALESTINE*.

GROUND, RICE. See *PALESTINE*.

GROUND, RICE. See *PALESTINE*.

GROUND, RICE. See *PALESTINE*.

GROUND-PLATE, in *Architecture*, are the outermost pieces of timber lying on, or near the *ground*, and framed into one another with mortises and tenons. In these also are mortises made to receive the tenons of joists, the fammers, and girders; and sometimes the trimmers for the flap-case and chimney-way, and the binding joists.

GROUND, of a Field, or *ground*, in *Horology*, is properly called the *ESTIM*.

GROUND, in Painting, is the surface upon which the figures, and other objects are raised or represented. See *PAINTING*.

GROUND is properly understood of such parts of the piece as have nothing painted on them, but retain the original colour, upon which the other colours are applied to make the representation.

A drapery, piece of building, or the like, are said to serve as a *ground* to a figure, when the figure is painted on the drapery, or building.

In the like sense, we also say, the *ground* of a piece of tapestry, of an embroidery, of a medal, coin, &c.

GROUND-TACKLE, a Sea Term, denoting a ship's anchor, cables, &c. with what is necessary to make her ride safe at anchor in a proper *ground*.

GROUND-TIMBERS, in a *Ship*, are those whose timbers lie on her keel, and are fastened to it with bolts through the keelson. They are so called, because the ship lies at rest upon them when she is in *ground*.

GROUND-WORK, in *Building*. See *FOUNDATION*.

GROUND-WORM. See *WORM*, and *EARTH-WORM*.

GROUNDAGE, a custom, or tribute, paid for the standing of a ship in a port. See *BLOUNT*.

GROUNDING of a ship, is the bringing her on *ground*, to be trimmed, made clean, or to have some leak stopp'd in her.

The term is also applied to a ship's running aground accidentally, when under sail, or driving in a tempest.

GROUNDING, an English name for that small species of the robin, more commonly called the *LOACH*, and by Arabs the smooth-spotted *COBITAS* with the body cylindrical.

GROUNDSEL, *Senecio*, in *Botany*, a genus of the *symplesia* *polygamia* *superflua* class. Its characters are these: the flower is composed of many hermaphrodite florets, which form the disk, and female half-florets, which make the border, or rays, included in one common cylindrical empalment, which is rough, fealy and contracted above; the hermaphrodite florets are tubulous, funnel-shaped, cut into five parts at the brim, which are reflexed; they have five small hair-like stamina, terminated by cylindrical funniform; and an oval germen, crowned with down, situated under the petal, supporting a slender style, crowned by two oblong revolving stigmas; the germen afterwards turns to an oval leaf, crowned with down, included in the empalment; the female half-florets, which form the rays, are stretched out like a tongue, and are included in three parts at the top. There are many species of *groundsel*, which are common weeds; but Miller mentions some species of it which are cultivated as more valuable. Linnaeus has annexed to this genus several species of *Tournefort's* *AGNOSTOS*.

The leaves of the common *groundsel*, taken in a strong infusion, are an emetic. Dr. Lewis conjectures that their emetic power may be merely owing to large doses of the infusion, by which the stomach was nauseated. It is prescribed in smaller doses in dropsies, jaundices, and hemorrhages. Externally they are used in ointments against cutaneous foulnesses. Beat into a very coarse pulp, and applied cold to the pit of the stomach, they have had very good success in curing agues. They are to be used only on the days free from the fit. They vomit strongly some hours after application. See *Medic. Edinb.* vol. ii. art. 5; or *Abridg.* vol. i. p. 203.

GROUNDIEL, *African*. See *Foreign COLTPOOT*.

GROUNDIEL, *German*. See *STELLERA*.

GROUP, or *GRUPPE*, in *Painting* and *Sculpture*, an assemblage, or knot, of two or more figures of men, beasts, fruits, or the like, which have some apparent relation to each other.

The word is French; formed of the Italian *gruppi*, a knot, or cluster.

In a good painting, it is necessary that all the figures be divided into two or three *groups*, or separate collections. Such and such a thing make a *group*, with such and such others of different nature and kind. The unique *Laocoon* is a fine *group* of three beautiful figures.

A *group* has somewhat in it of the nature of a symphony, or concert of voices; as, in the one, the voices must sustain each other, in order to fill the ear with an agreeable harmony from the whole; whereas, if any part were in discord, something would necessarily be missed; so in the other, if the parts, or figures, be not well balanced, something will be found disagreeable.

There are two sorts of *groups*, or two manners of considering *groups*; with regard to the design, and to the clear-obscurity. The first is common both to works of painting, and those of sculpture; the latter is peculiar to painting.

Groups, with regard to the design, are combinations of divers figures, which have relation to each other, either on account of the action, or of their proximity, or of the effect they have. These we conceive, in some measure, as representing to many different subjects, or at least to many distinct parts, or members of our greater subject.

Groups, with regard to the clear-obscurity, are bodies of figures wherein the lights and shadows are diffused in such a manner, that they strike the eye together, and naturally lead it to consider them in one view.

In *Architecture* we sometimes say, a *Group of columns*, speaking of three or four columns joined together on the same pedestal. When there are but two together, we say, a *couple*, not a *group of columns*.

Two or more figures, that are in any way connected, are called a *group*; and they are said to be well or ill *grouped*, when they are or are not happily situated. See *Tab. Arch. fig. 46. H.* Figures, though in the same situation, and joined to each other, if not connected in the design, are not said to be *grouped*, but are single *figures*; such are those in the screen of columns, and round the Aedicule, under the dome, in the wings of the building.

In *Style*, a *Group* is one of the kinds of diminutions of long notes, which in the writing forms a sort of *group*, or cluster.

The *group* usually consists of four crotchets, quavers, or semiquavers, tied together, at the discretion of the composer.

GROUP-DES is a term used in the *Mange*, for *groupes*.

GROUPED above. See **COLUMN**.

GRONSE, or GRON, in Ornithology, is a general name comprehending several species of birds, which Linnaeus has classed under the genus of *Tyrannus*. Their general character is, that they have a short arched bill, that the outermost and inner toes are connected to the first joint of the middle toe by a small membrane; their legs are feathered to the feet; they have broad scarlet eye-brows. The *grand gron*, called also the *agallus major*, and cock of the mountain, or wood, is the *terras agallus* of Linnaeus. The male of this species sometimes weighs fourteen pounds; its bill is of a pale yellow colour; the nostrils are covered with dusky feathers; the head, neck, and back, are elegantly marked with slender lines of grey and black, running transversely. The feathers on the hind part of the head are long, and beneath the throat is a large tuft of long feathers. The upper part of the breast is of a rich glossy green; the rest of the breast and belly black, mixed with some white feathers; the sides are marked like the neck; the covers of the wings are crossed with undulating lines of black and reddish brown; the exterior webs of the greater quill-feathers are black, and at the setting on of the wings in bush pease is a white spot; the tail consists of eighteen black feathers marked on each side with a few white spots; the legs are covered with brown feathers, and the edges of the toes declinated. See *Tab. III. Birds, N° 25*. The bill of the female is dusky; its throat red; its head, neck, and back marked with transverse bars of red and black; the breast has some white spots on it, and the lower part is of a plain orange colour; the belly is barred with pale orange and black; the tips of the feathers are white; the feathers of the back and scapulars are black, the edges being mottled with black and pale reddish brown; the scapulars are tipped with white; the tail is of a deep red colour, barred with black, tipped with white, and consists of sixteen feathers. The female is considerably less than the male. See *Tab. III. Birds, N° 26*. These differences between the male and female led some writers to make the male and female of this species two distinct species; and Goussier has distinguished them in this manner, calling the female the *agallus minor*, and the male the *agallus major*. This species is found in no other part of Great Britain except the Highlands of Scotland, where it is known by the name of *capreolus*, and in the old law books, *capreolus*, the horse of the woods. It inhabits woods and mountainous countries, and feeds on the tops of pines and birches, and the berries of juniper. These birds are common to Scandinavia, Germany, France, and several parts of the Alps; and are generally reckoned well-tasted food. Another species of the *gron* is the black game, heath cock, or black cock, being the *terras agallus* of Linnaeus; the male, which is called the *agallus minor*, has a dusky bill; the plumage of the whole body is

black, glossed over the neck and rump with a shining blue; the covers of the wings are of a dusky brown, the inner covers white; the thighs and legs are covered with dark brown feathers, and on the former are some white spots; the tail consists of sixteen black feathers, and is much forked; the feathers under the tail are of a pure white. The weight of an old black cock is about four pounds.

The female weighs about two pounds; the head and neck are marked with alternate bars of dull red and black; the breast with dusky black and white; the back, covers of the wings and tail, are of the same colours with the neck; the inner covers of the wings are white; and in both sexes form a white spot on the shoulder; the tail consists of sixteen feathers, variegated with red and black, and slightly forked. This species of birds frequent the same situations with the former; they feed on bilberries and other mountain fruits, and in winter on the tops of the heath. In summer they often descend from the hills to feed on corn. They never pair, but in spring the male gets on its enemies, crows, and chaps his wings; on which signal all the females within hearing resort to him. The hen lays from six to eight eggs, which are hatched late in the summer. The young males, which quit their mother in the beginning of winter, keep together in flocks of seven or eight till spring, during which time they inhabit the woods. There is another variety of the black cock, which differs from the common sort in being spotted on the neck, breast, wings, and thighs, with red; such is also the *terras hybridus* of Linnaeus. Pennant.

Another species of *gron* is the red game, moor-cock, or *gonnack*. A fourth species is the white game, *terras lagopus* of Linnaeus, or *PARADISE*.

GROUT, or GRUNT, in Building, is a very thin coarse mortar; when it is mixed with bullock's hair, it is called *hair-grout*. See *Estimating of Works*.

GROWAN, in Natural History, was used by the miners in Cornwall to express a sort of coarse and gritty stone, which they are usually obliged to dig through before they come at the veins of ore. This is usually grey or whitish, but sometimes it is of various colours, often yellowish, and sometimes spotted with iron-colour, and an ashy black; and often its texture is so loose and spongy, that there are holes in it of the size proper to receive a pea or a horse-bean; these are sometimes empty, but more usually they are filled up either with chalk or with spar. Beside the strata of this stone that lie over the ore, there is also a large quantity of it often placed by its side. They have this, and two other sorts of stone, lying in the way to the tin ore in Cornwall. The first of the others they call *marl-stone*, a very uncertain name, as it is also given by some to the common white granite of that country; but the miners only mean by it a loose sort of free-stone, somewhat softer than that usually employed in building. The other stone is called *tilite*; this is a grey stone of the fine kind, easily splitting into thin plates, and is very full of talcy flakes; this *tilite* is, however, a very indeterminate name, as well as the other, for the same people sometimes use it also to signify a white earth common among them; this last, however, they sometimes distinguish by the epithet *white*. The word *growan* seems the only name they have kept to any determinate signification, for they never express by this word any other substance than the stone above described.

GROWING, in Sea-language, denotes the direction of the cable from the ship towards the anchors; thus, the cable *grows* on the starboard bow, when it stretches out forwards on the starboard or right side.

GROWME, in our Old Writers, an engine to stretch woollen cloth after it is woven; it is mentioned in the form: *Edw. III. cap. 10*.

GROWTH *happens*, a rat is called; and paid in some places for the tithes of every fat ox or other unfruitful cattle.

GRUARD, in our Old Writers, the principal officers of the forest in general. The word comes from the old French *gruyer*, which signifies the same.

GRUB, the English name of the hexapode worms or maggot hatched from the eggs of beetles. See **SCABAEUS**. Grubs are an excellent bait for many kinds of fish. In angling for the grayling, the *sh-grub* is to be preferred to all others. This is plump, milk-white, but round from head to tail, and has a red head. There is also another *grub*, which is very common, and is longer and slenderer than the *sh-grub*; it is yellower and tougher, and is known by having a red head, and two rows of legs all along the belly. The trout and grayling usually frequent the same places, and it is not uncommon to take the trout, while fishing for the other. These *grubs* are to be kept in bran, in which they will grow tougher than they were at first; but the *sh-grub* is always tender.

tender, that it is difficult to make a good bait of it. The best method is to wrap it in a piece of flax hair with the arming, leaving it flapping out about a finger's breadth at the head of the hook, so as to keep the grub from totally slipping off when baited: the horse-hair that the hook is fastened to should be as white as possible, that it may resemble the colour of the bait, and not be suspected.

GRUB of the box, or *des-puerres*, in *Natural History*; a name given to a sort of insect approaching to the nature of the *puerre* of the elder and other trees, but differing from that animal in some essential characters, and being more properly of the same genus with the fig-insect or false *puerre*. Reaumur's *Hist. Nat. vol. vi. p. 100*. See *FIG-INSECT*.

These insects change their skin several times, in the manner of the *puerre*, and they change their colour at the same time. They are at first reddish, but they are then extremely small; after this they throw off a skin and become yellowish; after this they are of a deeper yellow, spotted with black; and finally, when at their full growth, they are greenish, and have black antennae. The exuvia which these creatures leave behind them, have often a grain of the excrement remaining fixed to them.

Mr. Reaumur, who took great pains to know the history of these minute animals, found that they finally became flies of a peculiar kind, resembling those of the fig-insect; they hopped, in the manner of grasshoppers, but only a little way at a time, and he was able to discover the parts peculiar to the male and female sex, in the different individuals, but never could find any eggs or embryonals in the latter.

GRUBS, *vermi*, in the *History of Insects*. See *VINE*.

GRUB-WE, or *Gaubuage*, among *Gardeners*, a tool for grubbing up the roots of trees, weeds, &c.

GRUBBING, the term used by our farmers to express the taking up the roots of trees out of the ground. Several occasions offer for the doing this; as when trees are old and past growing to any use, the roots must be taken up, that young trees may be planted in their place. This is a chargeable operation in most places, but in some countries the farmers have devised a machine, which does a great part of the work in a much shorter time than in any other way can be done. It is a hook of iron, of about two feet and a half long, with a large iron ring fastened to its straight end or handle. The whole instrument may be made for about three or four shillings, and is to be used in this manner: the ground is first to be cleared away about the root, and any straggling side-roots, found running horizontally, are to be cut off: they then fall on the point of the hook to some part of the stump or root, and putting a long and strong lever through the ring, two men at the end of it go round forcing it every way, till they tear the root out, twisting the tap-roots off at some distance under ground; the digging down to which, in the common way, is one great article of the expense. It is very effectual in flabbing up the roots of the underwood; but when large tree-roots are to be taken up by it, it is best to cleave them first with wedges into several pieces, then pull them out separately.

GRUBBING A WING, a term used, by cock-fighters, for the cutting off the feathers under the wings. It is a thing not allowed by cock-paw, nor to cut off his feathers in any handling place.

GRUBS, in *Medicine*, a white pocky kind of pimples, or little tumors, arising upon the face, chiefly the aim of the nose.

They are usually owing to hard drinking, and an obstructed perspiration through natural in some constitutions. They begin with a small black point, which gradually spreads; and sometimes the matter tends to suppuration, upon which the heads of the eruptions grow white or yellow. They are usually reputed salubrious; whence, to check their growth suddenly, has proved of ill consequence. They are cured by evacuation, and acrimonious lotions.

GRUINA, the *crumey*, a name given by some authors to the *TIPULA*, or fether-long-legs, from its legs being like those of a crane. See *CRANE-FLY*.

GRUME, *GRUMUS*, in *Medicine*, &c. a little mass or lump of blood, milk, or other fluid, which is coagulated, thickened, hardened, &c. Phlegmatic people frequently spit up *grume*, i. e. clots of blood.

Grumes of milk are what we popularly call *curds*.

GRUMOSE, *radix*, are those which are composed of several small knots; such are those of the anemones, and of the littlecelandine.

GRUMOUS *blood* denotes that state, or confidence, of the blood, wherein it is too viscid and thick, for a due, brisk circulation; the effects whereof are, that it stagnates in the capillary vessels, and produces divers diseases.

GRUNDEL, or *GRUNDLING*, in *Ichthyology*, a name used by some for the common loach, or loche, a small fresh water fish, known among writers by the names of *cobitis* and *fundulus*.

GRUNDLING, in *Ichthyology*, a name given also by the Germans to the *elohis fuciatilis*, or common gudgeon.

GRUNDULUS, in *Ichthyology*, a name given by *Figulus*, and others, to the fish called by us the *loach*, or *grundling*. It is a species of *cobitis*, called by authors in general *cobitis herbata*, and *elohis fuciatilis*. Arted has distinguished it by the name of the smooth spotted *COBITIS*, with the cylindric body.

GRUNNIENS *pisces*, the *grunning fish*, the name of a fish caught in many parts of the East Indian seas, and called by the Dutch there *gurnet*. It seems of the gurnet or gurnard kind, and nearly related to the *gusbi-conra* of the Brasilians. When it is first taken out of the water, it makes a remarkable grunning noise. It has two side lines on each side, running from the gills to the tail: the one of which is brown, and the other yellow; it is covered with very small scales, and is a very fat and fleshy fish; it grows to about six or seven inches long, and its head is large and ill shaped; it is a very well tailed fish.

GRUPO, or *gala*, in *Music*, was introduced into England by a gentleman who learned it of the famous *Scipione del Falla* in Italy. It consists in the alternate progression of two tones in juxtaposition to each other, with a close on the note immediately beneath the lower of them. This is the chief grace both in vocal and instrumental performances.

GRUS, in *Antiquity*, a dance performed yearly by the young Athenians, around the temple of Apollo, on the day of the Delia.

The motions and figures of this dance were very intricate, and variously interwoven; some of them being intended to express the windings of the labyrinth whereto the Minotaur was killed by Theseus.

GRUS, in *Astronomy*, a Southern constellation not visible in our latitude. The number of stars in this constellation, according to Mr. Sharp's Catalogue, is 123; the Situation longitude, latitude, and magnitude of which, are as follow:

Names and Situations of the stars	Right Ascension	Longitude	Latitude	Magnitude
In the head	11 35 18	24 58 3	5	
In the middle of the neck	12 3 37	26 5 46	5	
In the inferior of the neck	10 8 48	17 4 5		
	10 14 43	17 10 5		
In the back	17 44 1	11 10 31	5	
5				
In the right wing	17 41 17	11 53 56	5	
	16 58 33	16 43 54	5	
	16 57 41	10 11 34	5	
In the left wing	12 8 9	12 10 31	5	
In the root of the tail	18 23 38	23 10 8		
10				
In the tail ad	6 40 58	39 43 0	4	
11	14 58 31	11 24 0	5	
31	18 2 7	41 55 14		

GRUS. See *CRANE*, and *Tab. II. of Birds*, No 17.

GRUS JULIENUS. See *CRANE*, and *Tab. of Birds*, No 7.

GRY, a measure containing one tenth of a LINE.

A line is one tenth of a digit, and a digit one tenth of a foot, and a philosophical foot one third of a pediculus, whose diastemes, or vibrations, in the latitude of forty-five degrees, are each equal to one second of time, or one sixtieth of a minute.

GRYGALLUS, in *Ornithology*. See *GRUPE*.

GRYLLOTALPA. See *BLAT CAECIEN*.

GRYLUS. See *CAECIEN*.

GRYLUS, in *Ichthyology*, a name given by some to the *CONGRUS*, or *sea-eel*. *Riccius*, who has given commentaries on *Oppian's* *Halieutica*, has given this word as the translation of the *gongrus* of that author, which is the name of the same fish with the *congrus* of Aristotle, and the other ancient Greeks. Arted has avoided the occasion of any such errors for the future, by not allowing it any generic name at all. He makes it a species of his genus of *MURANA*, and distinguishes it from all the others by the name of the *murana* with the rim of the back-fin black.

GRYLUS vulgaris, in *Ichthyology*, a name given by *Gesner*, *Bellonius*, and others, to the *ORUSSIUM* of the generality of authors; distinguished by Arted by the name of the *ophidion* with four cirri, or beards, at the lower jaw. *Pliny* has mentioned this under the name of the *psittacus conus similis*.

GRYPHITES, in *Natural History*, the name of a very common fossil shell, the recent, or living fish, to which it belongs, not being known.

The *gryphite*, according to De Cotte, is the fossil oyster-shell. Conchol. p. 250.

It is an oblong shell, very narrow at the head, or cardo, and gradually becoming wider to the extremity, where it ends in a circular limb. The head or beak is very elevated, or much bent forward. It has been called by some the *testes amma regibus* by others they are called *ancha regis*, and they are commonly known among us by the name of *crum-fish*. They are very frequent in many parts of the kingdom in our gravel-pits and clay-pits, and we seem to have three or four distinct species of them. Some are extremely rounded and convex on the back; others are left so, and the plates of which they are composed are in some smaller and thinner, in others much larger and thicker, in specimens of the same bivalve. Hill's Hist. of Fossils, p. 650. See Tab. III. p. 20. of 9.

GRYPHUS, *gr.*, the *griffin* class, a name of a chimerical instrument deficient by a whole Part, and used for extruding snakes from the uterus.

GRYPHUS, one of the many names used by chemists for the philosophers stone.

GAYETTE, in Surgery, a sort of crooked pincers used by surgeons.

GAYETUS is also a kind of *EXIGMA*, or an awful obscure description of a thing.

GRYPHOS, of *gryphos*, *traded*, in Medicine, the name of a discomposure of the toe-nails, in which they bend inwards, and make their way deep into the flesh.

GUABANI, in Botany, the name of a delicious fruit in the West Indies, cooling, and of a sweet taste.

GUACAGUACA, in Ornithology, the Brazilian name of a bird of the larva, or gull kind, the eggs of which are much valued in America, but the flesh not at all. It is called by the Portuguese there the *GAYOTA*.

GUACARIL, in Ichthyology, the name of an American fish of a roundish, or in some sort a pyramidal figure, and of a foot or more than that in its common length. Its head is flat below, and roundish on the upper part; its mouth is small and round, and is placed in the under part of the head, and is furnished with a sort of beard, of slender, but stiff bodies, resembling short segments of hog's bristles; its back-fins is somewhat prickly, as in the perch, and its tail is supported by strong nerves, and is very forked; its head is covered with a hard fleshy crust, which feels rough to the touch; and its body with triangular scales, which are larger toward the tail than near the head; and all of them are rough, as if they had been cut and ridged, and have a sort of tubercle in their middle; so that the whole fish seems covered with a coat of armour, and has a quadruple arrangement of tubercles on each side; it is all over of a pale salmon colour, but somewhat deeper on the belly than on any other part, and is all over variegated with brown spots, of the size of mustard-seeds.

There is also another kind of this fish, which differs in colour, being all over of a dusky brown, spotted with small specks of a fine deep black. They are both eaten; but the first kind has very little flesh; the latter has more, and it is also better tasted. Marcgrave's Hist. Brasil.

GUACUCUA, in Zoology, the Brazilian name of a kind of water-bat.

GUACUA, the name of a very remarkable Brazilian fish, called also by some the *testes aquatilis*, or water-bat, and by others the *monstrum piscis*. The anterior part of the body of this fish is like a plough; the head is eight fingers long, and five wide in the broadest part; the hinder part of its body is round, and pointed toward the tail; it is broad and flat, and the head scarcely appears beyond the rim of the body; and has between the eyes a single horn, which is very hard, of a conic shape, and near two fingers long; it has a tolerably wide mouth, but no teeth; and it has on each side, in the middle of the body, an arm, and under these, on the belly, has two fins which seem to serve as feet; it has a tough skin, and no scales; it is brown on the back, and is full of tubercles, and is red on the belly; in, most of all fish, approaches to the *rena piscatrix*. Marcgrave's Hist. Brasil. p. 39.

GUADUM, in Natural History, an herb, by the ancient Romans called *gylum* and *curum*; by the Greeks *gylis*; by the Britons *gudum*; and by us *WOOD*.

The ancient Romans, Celsus informs us, painted their faces with this herb, to appear more terrible to their enemies; and Pliny relates, that the same was practised by the women in direct sacrifice.

GUAIACANA. See *Indian Date PLUM*.

GUAIACUM, *liquor vitae*, or *pickard*, in Botany, a genus of the *decidua myrica* class. Its characters are these: the flower has a concave empanement: it hath five oblong, oval, concave petals, and ten erect stamens, which are inserted in the empanement; the germin, which is oval and pointed, afterward becomes a berry, which is

roundish, with an oblique point, and deeply furrowed, enclosing one oval hard seed. There are three species.

The common *liquor vitae*, or *guaiacum*, which is used in medicine, grows naturally in most of the islands of the West Indies, where it becomes a very large tree, having a brownish, hard, brittle bark, not very thick; the wood is solid and penderous, very resinous, of a blackish yellow in the middle, and of a hot aromatic taste; the smaller branches have an ash coloured bark, and are garnished with leaves divided by pairs; each pair having two pair of small oval blunt points, of a stiff consistence, and a lucid green; the flowers are produced in clusters at the ends of the branches, composed of five oval concave petals, of a fine blue colour; in the centre of these is fixed a style with an oval perianth, crowned by a slender stigma, and round this is fixated a great number of stamens, which are as long as the style, terminated by sickle-shaped funnels. Dr. Linnaeus supposes the flowers to have but ten stamens, whereas they certainly have twenty, so it should be ranged in his twelfth class of plants; nor is it the empanement, but the germin which becomes the fruit. The bark and wood of this tree are much of the same nature, only the wood is accounted better; they are used in dist drinks, to purify, and cleanse the blood, and to cause sweating; they are esteemed good for the gout and dropsy, the king's evil, and particularly for the French pox. The gum or resin, which exudes from incisions made in the trunk, is black, shining, and brittle, and when powdered, of a greenish white colour, of an aromatic smell, and poignant taste; is somewhat cathartic, and a good purge in rheumatic colic, to the quantity of two scruples mixed with the yolk of an egg, and given in a convenient vehicle.

The wood of this tree is so hard as to break the tools in felling them, so that it is seldom cut down for fire wood, being difficult to burn; but it is of great use to the sugar planters for making wheels and cogs for sugar mills. It is also frequently brought to Europe, and wrought into bows and other utensils. Miller.

But its principal use is in medicines; being found to warm, dry, rarely, attenuate, attract, and promote sweats and urine. Where the excretory glands are obstructed, the vessels lax and flaccid, and the habit replete with impure ferous humours; in various cutaneous and catarrhus disorders, some female weaknesses, and chronic rheumatism, it frequently has good effects; but in thin emaciated habits, and an acrimonious state of the fluids, it frequently does harm. The usual way of applying it is in decoction, and a decoction of half an ounce of the wood or bark may be taken in a day at proper intervals, the patient keeping warm, to promote a diaphoresis.

Decoctions of this wood taken internally, as also applied in fumigations externally, have been found of service in cancerous disorders. See *Med. Lib. Edinb.* vol. vi. art. 9. It is a very remarkable quality of *guaiac*, that the salt it yields has very little of the alkaline quality of other salts of that kind.

The bark is that in large pieces, of a dusky colour, fresh, gummy, heavy, of an agreeable smell, and a brisk pungent taste; the bark sticking close to the wood.

The bark of *guaiac* is held of nearly as much virtue as the wood itself; the rind is of no efficacy; so that, to make a sordid decoction, or tincture, of the wood, they first pare off all the white part, which, in reality, is the rind, and only chip or rasp off the hard, solid part, which is black, heavy, and resinous. The surgeons frequently substitute box-wood instead of *guaiac*, and it is said, with equal success.

The resin drawn from *guaiac* is held much more effectual in venereal cases than either the wood, or bark. It is brought us in large pieces, not unlike common resin, but very different in respect of smell; the former, when cast on the coals, yielding a very agreeable balsamic fume. The resin, which is the only active part, is obtained pure from the gummy substance, and from the woody and other indissoluble impurities, by digesting the compound, in rectified spirit, drawing off the spirit from the filtered solution, till the matter begins to grow thick, and then adding a quantity of water, which will precipitate the pure resin, and keep dissolved such of the gummy parts as the spirit may have taken up. A quantity of the gum will yield about three-fourths of its weight of resin.

The resinous matter of the wood is totally extracted by digestion in rectified spirit, and partially by boiling in water. During the inspissation of the water decoction, the resinous part is apt to separate and subside, unless a little spirit be added towards the end of the process, to keep it united with the gummy. This extract is kept in the shops in a soft and hard form; the first of a proper consistence for making into pills, the latter for being reduced into powder. The quantity of solid extract obtained by rectified spirit, amounts to about one fourth of

the weight of the wood, with water scarce one sixth is obtained. The extract is recommended by Hoffman as an excellent ERMETIC. The gum, or extracts made from the wood, are given from a few grains to a scruple, or half a dram; and sometimes two scruples, which last dose commonly proves in a considerable degree purgative. Solutions and infusions of this gum *guaiacum* are made in the shops, both in the rectified spirit of wine and sal volatile. The *Pharmacopœia* of the London pharmacopœia is made by adding six ounces of the gum two pints and a quarter of sal volatile spirit; and for a more saturated solution, one pint and a half of rectified spirit of wine, with the addition of a dram and a half of balsam of Peru; and the *Pharmacopœia* of the Edinburgh college, by dissolving four ounces of the *guaiacum*, with two drams of balsam of Peru, and half a dram of essential oil of Sassafras, in a pound and a half of dissolved spirit of sal ammoniac; and the spirituous solution, by dissolving one pound of the gum and three drams of balsam of Peru in two pounds and a half of rectified spirit. There may be given from twenty drops to a tea-spoonful or more in any convenient vehicle. The gum, or resinous extracts, may also be dissolved by means of thick mucilage in watery liquors; and it is observed, that the mucilaginous solution, which is at first greyish or brownish, changes in a few hours to a fine blue or bluish green colour. Lewis.

The *guaiac* wood is distilled by putting thin shavings of it into a stone-water retort, to which is to be fixed a large glass receiver, with a small hole pierced in its side; and the distillation is to be promoted by a gradual fire. A liquor, like water, is obtained first, and then an acid, reddish, empyreumatic liquor, with a little reddish oil. In this process a considerable quantity of air is discharged; which proves that this element is combined in certain bodies, and particularly in this. Dict. Chem. art. GUYAC.

GUAIABA, *Phytum, bay plum*, in Botany, a genus of the *myrsinacea* monogynia class. Its characters are these: the flower has a bell-shaped empanclement, divided into five oval points at the top; it hath five oval, concave, spreading petals, indented in the empanclement, with a great number of laminae, which are shorter than the petals, and are inserted in the empanclement, terminated by small fimbriae; it has a roundish greenish ovary under the flower, supporting a long oval-shaped style, crowned by a simple stigma; the germen becomes a large oval fruit, crowned by the empanclement, inclosing a great number of small seeds. There are two species, which grow naturally in the East and West Indies. The common red *guaiava* hath a thick trunk, which rises twenty feet high. After the flower is past, the germen becomes a large oval fruit, thurst like a pomegranate, having one cell crowned by the empanclement of the flower, and filled with small seeds; the fruit, when ripe, has an agreeable odour. They are much eaten in the West Indies, both by men and beasts; and the seed, which passes whole through the body, grows in great plenty every where. This fruit is very alluring, and nearly of the same quality with the pomegranate; so should be avoided by those persons who are subject to be colic.

These plants are propagated by seed, which when brought over in the fruit, gathered full ripe, will more certainly succeed: these should be sown in pots filled with kitchen-garden earth, and plunged into a hot-bed of tanner's bark. In about six weeks, if the seed be good, the plants will appear, when they must have fresh air admitted to them, in proportion to the warmth of the season. When the plants are strong enough to remove, they should be each planted in a small pot, and plunged into a fresh hot-bed, shading them from the sun, until they have taken new root. In the summer they will require plenty of water, and in hot weather a great shade of air. With this management the plants will produce flowers and fruit the third year, and may be continued a long time. Miller.

GUABI *cara*, in Ichthyology, the name of an American fish, called by the Portuguese *barbat de villosa*. It is flat-bodied, with a rising back, and is usually caught between five and eight inches long, and of about a third part of its length in breadth. It is caught among the rocks and about the shores, and is eaten in considerable plenty in the Brasils, both by the natives and Portuguese. Marcgrave's Hist. Brasil.

GUMMINISQUE, in Ornithology, a name by which many authors have called the humming-bird, or *GUMMINISQUE*.

GUAINUMBI, in Ornithology. See HUMMING-BIRD.

GUAIACLING, in Ornithology, the name given by the people of the Philippine Islands to a species of bird of the flapping kind. It is of the bigness of the turtle; it feeds on fruits, and is a very brisk and lively bird. It appears to be of a plain black colour, except when viewed in the sun, and then is seen to be of a vast variety of

bright colours.

GUAMAJACU *api*, in Ichthyology, a name by which Marcgrave, and some others, have called the *pisces triangulares*.

GUAMAJACU *stings*, in Ichthyology, the name of a fish of the tern or globe-fish kind; which is thorny, and has the mouth of the ordinary frog-mouthed species. It is usually about seven fingers breadth long, and in the place of teeth has a hard bone above and below in its mouth. The holes for its gills are large enough to admit one's finger, and near these there are two square, broad, and short fins; its head is covered with a hard bony shell, and all its body with prickles, except on the belly, where it is soft as the belly of a frog; the prickles are so many small pointed bones. If cut, at pleasure, in late its whole body into the semblance of a bladder; it is not curable, but esteemed poisonous. Filo. Hist. Nat. lib. v. cap. 10. See Tab. Fish. N° 2.

GUAMAJACU *gama*, in Zoology, a name by which some call that species of the *hystrix*, or sea-porcupine, called by Marcgrave *DIARE*.

GUANA, in Zoology, a species of LIZARD.

GUANABANUS, a name by which Plumier, and other authors, have called several species of the annona. See ANNONA.

GUAPERVA, in Ichthyology, the name of an American fish, of the toad-fish, or *rana-piscatrix* kind, but different from that in many things, and remarkably small. It is seldom found of more than four fingers' breadth long, and its more useful size is but two fingers; it has no gills; its mouth is large, projected like that of a dog, and furnished with extremely small teeth; it has a bone, supplying the place of a tongue; its eyes are extremely small, and of a fine pale blue, like that of the turpock; between its eyes, or in the middle of its upper lip, it has a little horn, standing upright, but bending a little backward, and before that horn is a slender filament, half a finger long, turned backward, and with a little button at its end; it has one large fin upon its back, and two smaller on its belly or breast, and in the middle of its body, but rather nearer the head; it has on each side an arm, which toward the extremity degenerates into a fin, and is prickly at the end; it has no scales, but a rough skin, rough on the back, and smooth on the belly. It is of a reddish-brown colour, and spotted all over with large black spots. Marcgrave's History of Brasil, p. 137.

GUARA, in Ornithology, the name of a Brazilian bird, called by Glossus *ruminus Indicus*, or the *Indian rufous*. It is a large bird, of the size of the plate, or spoonbill, and lives about waters; its beak is long, and of a whitish grey, figured like a Polish sword; the tail is short, and is hid by the wings when they are closed; it is all over of a fine gay red, only that the long wing-feathers are tipped with black at their extremities, and there is something very remarkable in its growth, for it is black when first hatched from the egg, from this it becomes greyish, and from this at length changes to its fine red.

GUARACAPEMA, in Ichthyology, a name used by some for the fish more usually called the *DORADO*, or *auratus piscis*.

GUARANTEE, or WARRANTEE, in Law, a term relative to *warrant*, or *warranter*; properly signifying him whom the warrant undertakes to indemnify or secure from damage.

GUARANTY is more frequently used for a warrantor, or a person who undertakes and obliges himself to see a second person perform what he has stipulated to the third. See WARRANT.

GUARANTY, in Politics, an engagement of mediatorial or neutral states, whereby they pledge their faith, that the articles of a particular treaty shall be invariably observed on both sides.

This engagement implies, that the guaranties are obliged to assist the party invaded contrary to the treaty, against the injurious aggressor; but not if the war is occasioned by any other cause than the violation of the articles of peace. Vattelot, Law of Nature and Nations, book viii. ch. 8, § 7.

The ancient lords were obliged to *guaranty* the lands of their vassals, i. e. to defend them against their enemies; otherwise they lost their *fee*, and their vassals were no longer bound to do them homage and service. Kings alone did not forfeit their *fees* by not *guarantying* them; and yet we read, that Borel, count of Barcelona, threatened the king of France, Hugh Capet, to treat fealty to the Saracens, in case he did not *guaranty* him; and under Lewis the Young, the count of Champagne did homage to the emperor, on the like account.

To *guaranty* a fee, had likewise another meaning; being used to denote that where a fee was divided between the eldest son and the younger, the eldest did homage to the lord, both for himself and all the rest; and by that homage *guaranteed* the whole.

GUARA-TEREIA, in *Ichthyology*, the name of an American fish of the *Scomber* kind, approaching to the nature of the *trachurus*, and which Mr. Ray thinks may properly be called the *trachurus brasiliensis*, or the *Brasiliian fish*. It is usually of about four or five inches in length; its head is obtuse, and its mouth furnished with very small teeth, the side-lines towards the tail are armed with prickly hooks, all pointed backwards; the tail is divided into two horns. It is eaten in Brazil, and other American countries.

GUARAUNA, in *Ornithology*, the name of a small Brazilian bird common in watery places, and of the size of our snipe. Its bill is straight, but a little hooked at the end, and is between four and five fingers breadth long; its body is about the same length, and its legs six fingers long; it is all over of a dusky brown, with an admixture of a cast of greenish; it is a well-tufted bird.

GUARD, or **GUARD**, in its general sense, implies defence, custody, or conservation, of any thing; the act of observing what passes, to prevent surprise; or the care and precaution taken to hinder any thing's being done contrary to the intention and desire of another.

The word is formed of the French *garde*, and that of the corrupt Latin *wardo*, and that of the German *wahren*, is *to keep*, *to defend*.

GUARD is also used in a figurative sense, for the act or service of guarding, and the persons appointed for that purpose.

Thus we say, to be upon guard, to set the guard, mount the guard, to dismount the guard, to relieve the guard, to change the guard, the officer or sentinel of the guard, also, a strong guard, an attempt on the guard, &c. So, again, those to whom the king commits the safety of his person, are called his *guard*, *life-guard*, *body-guard*. And to those who have had the education and guardianship of infants, or idiots, are called their *guardians* or *wards*.

GUARD, or **GARD**, is also applied to a writ relating to the office of *ward*, whereby there are three kinds: one called *deut de garde*; the second, *justiciars de garde*; the third, *reignment de garde*. See **GUARDIAN**.

GUARD, in the *Military Sense*, is properly the duty or service done by the soldiers, to secure the army, or place, from the attempts and surprises of an enemy. In garrison the *guards* are relieved every day; so that every soldier mounts guard once every three or four days in times of peace, and much often in time of war. Of this there are divers kinds, as,

GUARD, *advanced*, a party of horse or foot, which marches before a corps, to give notice of approaching danger. See **ADVANCE**.

GUARD, *artillery*. See **ARTILLERY**.

GUARD, *artillery*, *quarter*, is frequently a non-commissioned officer's guard from the royal regiment of artillery, whose corps de garde is always in the front of their encampment.

GUARD, *artillery*, *rear*, consists of a corporal and six men, posted in the rear of the park.

GUARD, *baggage*, is always an officer's guard, who has the care of the baggage on a march.

GUARD, *boat*, in *Sea Language*, a boat appointed to row the rounds among the ships of war which are laid up in any harbour, &c. to observe that their officers keep a good lookout, calling to the *guard-boat* as she passes, and not suffering her crew to come aboard, without having previously communicated the watch-word of the night.

GUARDS, *camp*, are of two sorts; the one serves to maintain good order within the camp, and the other, which are stationed without the camp, serves to cover and secure it against the enemy. They are formed both of infantry and cavalry; and should consist, as the occasion requires, of the eighth part, or third part, or even of half the army, when an attack is apprehended. The cavalry *guards* are removed farther from the main army than the infantry; but not so far as to endanger their being cut off. These *guards* have generally a day post and a night post; the latter of which is seldom more than four or five hundred paces from the camp: the *guards* of infantry are generally fixed, except those that are to support and protect the cavalry *guards*, and to cover the forage grounds.

Corps de GARDE, or **GUARD**, See **CORPS**.

GUARD, *counter*, in *Fortification*. See **COUNTER-GUARD**.

GUARD, *forward*. See **FORWARD**.

GUARD, *grand*, consists of three or four squadrons of horse commanded by a field officer, and posted before the camp on the right and left wing towards the enemy, for the security of the camp.

GUARD, *iron*, in a *Ship*, are certain curved or arched bars of iron placed over the ornamental figures on a ship's head or quarter, to defend them from the impression of some other ship, when they lie close to or rub against each other.

GUARD, *main*, is that from whence all the other *guards* are detached. Those who are to mount the *main guard*, meet at the respective captains' quarters, and from thence they go to the parade; where, after the whole *guard* is drawn up, the small *guards* are detached for the posts and magazines; and then the forebore officers draw lots for their *guards*, who are all commanded by the captain of the *main guard*.

GUARD, *figure*, is a number of horse and foot, who keep themselves always in readiness in case of an alarm; the horses being generally saddled, and the riders hooded. The foot draw up at the head of the battalion at the beating of the tattoo, but afterwards return to their tents, where they remain in readiness to march on any sudden alarm.

This *guard* is to make resistance, in case of an attack, till the army can get ready.

GUARD, *front*, is always an officer's guard that attends the general in his rounds, to prevent desertion, marauding, rioting, &c.

GUARD, *quarter*, is a small guard commanded by a subaltern officer, posted in the front of each battalion, about two hundred and twenty-two feet before the front of the regiment.

GUARD, *rear*, is that part of the army which brings up the rear on a march; the rear *guard* of a party is frequently eight or ten horse, about five hundred paces behind the party. Hence the advance *guard* going out on a party, forms the rear *guard* in their retreat.

Rear Guard is also a corporal's guard placed in the rear of a regiment, to keep good order in that part of the camp. *Reform Guard*. See **RESEVE**.

GUARD, *safe*. See **SAFE-GUARD**.

GUARD, *ship*. See **GUARD-SHIP**.

GUARD, *standard*, is a small guard under a corporal, out of each regiment of horse, who mount on foot in the front of each regiment.

GUARD, *trench*, consists of three, four, or six battalions, according to the occasion, which mount in the time of a siege, in order to oppose the besieged when they sally out, protect the workmen, &c.

GUARD, *own*, is the same with the front of an army. See **ADVANCE** *guard*, and **ADVANCE** *GUARD*, above.

GUARD is more particularly understood of a soldier, as a musketeer, archer, or the like, detached from a company, or corps, to protect, detain, cut, or secure, any person, or to survey his actions.

GUARDS is also understood of the troops, or companies, kept to guard the king; called also *royal guards*, *life guards*, *guards de corps*, &c.

There are also usually bodies of *guards* to wait on the prince of the blood, in the same capacity.

The *guards* are distinguished into *horse*, *foot*, *grenadiers*, and *jeune*.

GUARDS, the *English horse*, are divided into troops, called *first*, &c. troop of *horse-guards*. See **HORSE**.

GUARDS, the *foot*, are distinguished by regiments; of which there are three, called the *first*, &c. regiment of foot *guards*. They were raised in the year 1660: the first regiment is commanded by one colonel, one lieutenant-colonel, three majors, twenty-three captains, one captain-lieutenant, thirty-one lieutenants, and twenty-four ensigns; and contains three battalions. The second regiment has one colonel, one lieutenant-colonel, two majors, fourteen captains, one captain-lieutenant, eighteen lieutenants, and sixteen ensigns, and contains two battalions. The third regiment is the same as the second. *Guards*, no doubt, are as ancient as monarchy: the remotest antiquity affords instances thereof.

The Roman emperors had for their *guard* the praetorian cohorts, established by Augustus, as Dion and Suetonius relate: those of the emperors of Constantinople were called *auxiliaria*.

Captain, colonel, brigadier, exempt of the *guards*, &c. See **CAPTAIN**, **COLONEL**, **BRIGADIER**, **EXEMPT**, &c. The French *guards* are divided into *these* *units*, and those without the palace: the first consists of the *garde du corps*, or *body guard*, part whereof see *garde de la maison*, &c. of the *Swiss*, of the limited *Swiss*, and the *guards* of the gate.

The *guards* without are the *gens d'armes*, light horse, musketeers, and two regiments of *guards*, the one French, the other Swiss.

The *guards du corps*, or *body-guard*, consists of four companies of horse: the first was anciently Scotch, and still retains the name, though it now consists wholly of Frenchmen; and not only the name, but they also retain the ancient phrase, or formula, of answering, which called upon, *I am here*.

The *Scotch guard* was first established in France by Charles VII. who chose himself a *guard* out of Scotch Scots as were sent by the earls of Buchan, Douglas, and other Scotch lords, to drive out the English.

GUARDS, *praetorian*. See PRÆTORIAN.

GUARDS, *whit*. See SCOTIARE.

GUARDY, in *Fencing*, an action or posture, proper to defend or screen the body from the efforts or attacks of an enemy's sword.

There are four general guards of the sword; to conceive which, it will be necessary to imagine a circle drawn on an upright wall, and divided into four cardinal points; viz. top, bottom, right, and left.

Now when the point of the sword is directed to the bottom point of the circle, and, consequently, the head of the sword tilted up to the top point, with the body inclining forwards, this is called *prime*, or the *first guard*. The *second guard*, which some improperly call the *third*, is when the point of the sword is directed to the right or second part of the same circle, a quadrant distant from the first, with the foot of the sword turned to the right, and the body raised proportionably. *Third*, or the *third guard*, is performed by directing the sword's point to the uppermost point of the same circle diametrically opposite to that of *prime*, in which case the body, arm, and sword, are in their natural disposition, being the mean between the extremes of their motion. *Fourth*, or the *fourth guard*, is when the point of the sword is directed to the fourth point of the circle, defending to the right as far as one fourth of tierce, with the external side of the arm and the flat of the sword turned towards the ground; and the body out of the line to the right, and the foot of the sword towards the line to the left. There is also a *quint*, or a kind of *fifth guard*, being the return of the point of the sword on the right, after traversing the circle, to the point of the prime whence it had departed; and yet with a different disposition of the body, arm, and sword.

These guards are also called, by the masters, *figures* and *postures*; and the common centre of all their motions is to be in the shoulder.

In all these kinds of guards, there are high *advanced*, high *retired*, and high *intermediate guards*, when disposed before the upper part of the body, either with the arm quite extended, quite withdrawn, or in a mean state.

Mean advanced guard, or, simply, *mean guard*, is when the sword is disposed before the middle part of the body. *Low advanced*, *retired*, or *intermediate guards*, are those where the arm and sword are advanced, withdrawn, or between the two extremes, before the lower part of the body.

Some will have prime the principal guard; others, quint; others, with better reason, tierce; because it consists of right lines, which are more easily defended than oblique ones, such as those of prime, second, quart, and quint.

GUARDS, in *Astronomy*, is a name sometimes applied to the two stars nearest the pole; being in the hind-part of the chariot, at the tail of the Little Bear.

Their longitude, latitude, &c. are among those of the other stars in the constellation *URSA MINOR*. One of them is the pole star.

GUARDANT, or GARDANT, in *Heraldry*, a term applied to a beast when born in a coat of arms full faced, or with his face turned towards the spectator, and thus appearing in a posture of guard or defence.

Heralds say, a lion is never so represented; but a leopard always.

GUARDIAN, or GARDIAN, is he to whom the charge, or custody, of any person, or thing, is committed.

The notion of guardian ANGELS is very ancient in the East.

In the convents of Franciscans, the officer is called *guardian*, who in the others is called *superior*.

In the order of the Garter, the officer, who in other military orders is called *grand-master*, is called the *fourteenth guardian* of the order.

GUARDIAN, *GARDIEN*, in *Law*, is a person intrusted with the education, tuition, &c. of such as are not of sufficient discretion to guide themselves, and their own affairs; as children and idiots.

The word *guardian*, with us, includes the offices both of the tutor and curator of the civilians; the tutor, for instance, had the government of a youth till he arrived at fourteen years of age; and the curator had the disposition and ordering of his effects thenceforward till twenty-five years of age; or the charge of a lunatic, during his lunacy: all which purposes our *guardian* alone answers; though with regard to lunatics and idiots, these officers are commonly kept distinct.

There are several sorts of *guardians*. The first are *guardians* by nature, viz. the father, and, in some cases, the mother of the child; for if an estate be left to an infant, the father is, by common law, the *guardian*, and must account to his child for the profits; and, with regard to daughters, it seems by construction of 4 and 5 Ph. & Mar. cap. 8. that the father might by deed or will

assign a *guardian* to any woman-child, under the age of sixteen; and if none be assigned, the mother shall in this case be *guardian*. The second sort are *guardians* for nurture, which are, of course, the father and mother, till the infant attains the age of fourteen years; and in default of father and mother, the ordinary usually assigns some discreet person to take care of the infant's personal estate, and to provide for his maintenance and education. There are also *guardians* in *focage*, who are also called *guardians* by the common law: these take place only when the minor is entitled to some estate in lands, and then, by the common law, the *guardianship* devolves upon the next of kin, to whom the inheritance cannot possibly descend. These *guardians* continue only till the minor is fourteen years of age.

But the ancient law relating to *guardians* is much altered by stat. 12 Car. II. cap. 24. which enacts, that "where any person has a child under the age of twenty-one years, and unmarried at the time of his death, it shall be lawful for the father of the child, whether born at the time of his decease, or yet to be born, to be, either by deed, or will, to dispose of the custody and tuition of such child while under age, or for any lesser time, to any person, populi-recusants excepted; which disposition shall be good against all persons claiming such child as *guardian* in *focage*, or otherwise." These are called *guardians* by statute, or testamentary *guardians*. And in case the father appoint no *guardian*, the ordinary may appoint one to look to his goods and chattels till the age of fourteen; at which time the child may choose a *guardian* himself; and for his lands, the next of kin on that side by which the lands descend may be *guardian*, as heretofore in case of a tenure in *fo-cage*.

The *guardian*, when his ward comes of age, is bound to give him an account of all which he has transferred on his behalf, and must answer for all losses incurred by his wilful default or negligence. To prevent contests, the *guardians* of large estates apply to and act under the direction of the court of chancery, accounting annually before the officers of that court: for the lord chancellor, by right derived from the crown, is the general and supreme *guardian* of all infants, as well as idiots and lunatics. The court of chancery may, and sometimes does, remove a *guardian* who abuses his trust, and appoint another in his room.

GUARDIAN, in *Civil* law, was an office which formerly belonged to the feudal lord, in virtue of his wardship of an heir-male, under the age of twenty-one, and of a female under fourteen. This wardship consisted in having the custody of the body and lands of such heir, without any account of the profits, till the age of twenty-one in males, and sixteen in females. These profits were claimed in lieu of knight-service, which the male was supposed capable of rendering at twenty-one, and the female by her husband at fourteen. However, if the female was under fourteen, when the lord's wardship commenced, he might keep her under ward till sixteen, by stat. Weill. 1. 3 Edw. I. cap. 23. This wardship was taken from the lord by the charter of Henry I. and transferred to the widow or next of kin. But this noble immunity did not continue long. When the male-heir arrived at the age of twenty-one, and the heir-female to that of sixteen, they might sue out their *livery* or *assizes*, i. e. the delivery of their lands out of their *guardian's* hands; but for this they were obliged to pay a fine, viz. half a year's profits of the land.

These *guardians* had also another kind of power over their infant wards, which was that of disposing of them in matrimony; and if the infants refused a suitable match, they forfeited the value of the marriage to their *guardian*; but if they married without his consent, they forfeited double the value. This right of selling the ward in marriage was expressly delisted by the statute of Merion, 20 Hen. III. cap. 6. Those grievances, and others of a similar nature, were first abolished by the lords and commons in parliament, in 1535; and this ordinance was confirmed by the Protector and his parliament in 1563 and they were finally abolished by the statute 12 Car. II. cap. 24. and by 20 Geo. II. cap. 43. and cap. 10. The same are also abolished in Scotland. See KENT'S *Services*.

GUARDIAN in *focage*. See GUARDIAN above, and SCOTAGE.

GUARDIAN of the *spiritualities* is the person to whom the spiritual jurisdiction of a diocese is committed, during the time of the vacancy of the see.

This *guardian* may be either such in law, i. e. *jura majoris*, as the archbishop, or of any diocese within his province; or by delegation, as he whom the archbishop, or vicar-general, does for the time depute.

The dean and chapter of Canterbury are *guardians* both

for the diocese, and the whole province, during a vacancy of the archbishopric.

GUARDIAN of the church. See **CHURCH-WARDEN**.

GUARDIAN, or warden, of the Cinqueports. is an officer who has the jurisdiction of the Cinqueports, with all the power that the admiral of England has in other places. Camden relates, that the Romans, after they had feasted themselves and their empire in our island, appointed a magistrate, or governor, over the east parts, where the Cinqueports lie, with the title of *comes litoris Britannici* per Britanniam, having another, who bore the like title, on the opposite side of the sea. Their business was to strengthen the sea-coast with munition, against the outrages and robberies of the Barbarians. And that antiquary takes our warden of the Cinqueports to have been erected in imitation thereof. Britannia, p. 223.

GUARDIAN of the pond. See **CONSERVATOR of the pond**.

GUARIBA, the simia Brasilica of Linnaeus, in Natural History. the name of a species of monkey found in the West Indies. It is of the size of a fox; its face is raised high, its eyes are black and flaming, and its ears small and round; its tail is very long, matted toward the end, and extremely moveable; the creature frequently twisting it round things to fasten itself by it; it is covered all over with fine black flaming hairs, except on the legs and part of the tail, where they are brown; the hairs are in strictly disposed all over the body, that the creature appears perfectly smooth; and they are much longer under the chin and throat, so that they form a sort of beard there. Ray's Syn. Quad. p. 152.

This species is found in prodigious numbers together in the woods, especially of Brazil and Guiana, and makes a very loud and frightful noise; and it is very common for one only to make a noise, and all the rest to form a main assembly round him. Margareve relates a very singular thing of this creature, in this respect, which he says he has frequently been an eye-witness to. They meet in great numbers before and after mid-day, when they form a large circle; and one placing himself above the rest, begins to make a loud noise; when he has sung thus by himself for some time, the rest all remaining in perfect silence, he lifts up his hand, and they instantly all join in a sort of chorus; this immoderate yell they keep up incessantly, till the same monkey, who gave the signal for their beginning, lifts up his hand a second time, on which they all cease, and become silent again in a moment. He then exalts his pipe alone again, and so finishes the business of the assembly.

These creatures carry their young upon their backs, and keep very nimbly with them from tree to tree, the young ones clapping flat round their body with their arms. They are very fierce animals, and can never be tamed. There is a species of this kind also much larger than these, which have a very long, black, hairy beard. These, as Margareve assures, are his positive knowledge, will often attack the negro women as they go through the woods, and lie with them by force.

GUARIGUAKU, in Ichthyology, the name of a small American fresh-water fish, seldom exceeding an inch and half in length, and of a very slender body. It is eaten, though very small, being very well tasted. It is caught in abundance in lakes and ponds.

GUASSEM, a word used by Avicenna, and some other authors, to express certain black scorbatic spots and blotches appearing on the skin.

GUATUCUPA, in Ichthyology, the name of a fish caught about the Brazilian shores. It grows to about two feet long; its back is a little elevated, its mouth small, and beset with sharp teeth; it has only one long fin upon the back, the rays of which are rigid and prickly. It is caught among the rocks, and is an extremely well tasted fish.

GUATUCUSA, in Ichthyology, the name of an American fish, approaching to the nature of the *carassius* of the Mediterranean, and called by some *carassus*. It is of an oblong shape; its back is a little prominent, but its belly perfectly flat and even; its usual length is from twelve to twenty inches. It is caught on the Brazilian shores, and is a very delicate fish.

GUAVA, in Botany. See **GUAIABA**.

GUAZAMA, in Botany, the name of an American tree, described by Plumier as of the nature of the cacao. They are both species of the theobroma of Linnaeus; but the *guazama* is peculiar in the structure of its fruit, which is of a somewhat globular figure, full of tubercles and perforations on the surface, and yet divided into five lodge-ments for seeds within.

GUDGON, in Ichthyology, the English name of the fish called by authors the *gadin*, and *gabin flavicatus*. According to the new Animal System, the word *gadin* is made the name of another genus of fishes, and the *gudgon* is reduced to the genus of the *cyprin*. See **FUNDULUS**.

There are two species of the *gudgon*. The first is our common river *gudgon*, the *gypsinus gadin* of Linnaeus, with eleven rays in the anal fin, and two cirri, known by its thick and rounded body, the smallness of its scales, its brown colour, with the variegations of its black spots, and its forked tail. The second is the lesser river *gudgon*, differing from the former in being in size but in being of a more sipping body, and having very small fins toward the tail, and being of a more slender and less spotted. The first is common in the river Rhine (the *Gudgon Fiuminis*); the second is found in Germany, where it is commonly called *gudgon*.

GUDGON, in Architecture, the name by which some have called the fish more usually known by the name of the *gudgon*, a kind of sword-fish.

GUELPHS, or GIBELINS, a celebrated faction in Italy, antagonists of the Ghiblins.

The *Guelphs* and *Gibelines* filled Italy with blood and carnage for many years. The *Guelphs* stood for the pope, against the emperor. Their title is referred, by some, to the time of Conrad III. in the twelfth century; by others, to that of Frederic I. and by others, to that of his successor, Frederic II. in the thirteenth century.

The name *Guelph* is commonly said to have been formed from *Welf, Welfs*, on the following occasion: the emperor Conrad III. having taken the duchy of Bavaria from Welf VI. brother to Henry duke of Bavaria; Welfs, assisted by the forces of Roger king of Sicily, made war on Conrad, and thus gave birth to the faction of the *Guelphs*.

Others derive the name *Guelph* from the German *Welf*, on account of the grievous evils committed by that cruel faction. Others derive the denomination from that of a German called *Guelph*, who lived at Pilsen; adding, that his brother, named *Gohel*, gave his name to the *GIBELINS*; under which head the reader will find more ample account of the origin and history of those celebrated factions.

GUERITE, in Fortification, a sentry-box; being a small tower of wood, or stone, placed usually on the point of a bastion, or on the angles of the shoulder, to hold a sentinel, who is to take care of the ditch, and watch against a surprise.

GUERIN, or GIBERIN, a kind of cucumbers for pickling.

GUERNSEY fish. See **AMARYLLIS**.

GUESDA, in History, is properly the name of wood; but it is also used by some for the *lutum*, or *lutabris* of the Romans, and *cyane* of the Greeks. This is an error in too many of the old authors, though so palpable that one would have thought no body could have run into it; the *lutum*, or *cyane*, having been always said to dye yellow, and the *glauum*, or *guelph*, to dye blue; and the characters of the *lutum*, or *cyane*, plainly shewing it to be our *guistula tinctoria*, or dyer-wood, but not at all agreeing with the *glauum*, or wood.

GUEST-ROPS, or GUEST-ROPS, is that rope by which the boat is kept from drifting, or going too much in and out, as the line in the tow of a ship.

GUEST-TAKERS, or GUEST-TAKERS. See **AGIST-TOP**.

GUELT. See **WATCH**.

GUETTARDA, in Botany, a genus of the *monocotyledon* class, bearing male and female flowers in a cylindric cup; the corolla of each is divided into five segments, and that of the male funnel-shaped; the female has a single pistil, and the fruit is a dry drupe.

GUFELE, in Architecture. See **GULA**.

GUFFER, in Ichthyology. See **REIPPO**.

GUIANA-BIRD, in the Materia Medica, the same with what is otherwise called *simulacra*.

GUIDA, in Italian Music, the guide, or leading voice, or instrument, in figures. The parts that are to imitate and follow, are said to be in *responsione*. See **VOCE**.

GUIDAGE, GUIDAGIUM, in ancient Low-Latin, money paid for safe-conduct through unknown ways, or a strange country.

GUIDES, in Military Language, are usually the country people in the neighbourhood of an encampment; who give the army intelligence concerning the country, the roads by which they are to march, and the probable route of the enemy.

GUIDON, a sort of flag, or standard, borne by the king's life-guard; being broad at one extreme, and almost pointed at the other, and fit, or divided, into two.

The *guidon* is the ensign, or flag, of a troop of horse-guard.

GUIDON, in Architecture, the officer who bears the *guidon*. The *guidon* is that in the horse-guard, which the ensign

is in the foot. The *guidon* of a troop of horse takes place next below the cornet.

GUIDONES, **GUIDONES**, or *fibula guidonum*, was a company of priests established by Charlemagne, at Rome, to conduct and guide pilgrims to Jerusalem, to visit the holy places: they were also to assist them in case they fell sick, and to perform the last offices to them in case they died.

GUIDONIA, in *botany*, the name given by Plinier to the plant called afterwards by Linnaeus *SAMYDA*, and supposed to be allied to *ocymella*.

GUDONIA *Linnaeus* was an intimate friend of the illustrious **GIACINTO**, *Linnaeus*, a genus of the *decandria monogamia* class of plants. Its characters are: the corolla of the flower is bell-shaped, but at the time it issues five equal parts; the flower has five concave five-toothed petals, which are equal, inserted into the corolla; in the centre it is situated an oblong germ, which becomes a rhomboid pod, with a coarcture on the upper side, having one cell, including a hard seed, separated by partitions. There are five species, natives of different parts of the East and West Indies.

The feeds, which are called *Moiorea* nuts, are esteemed good in colics and hernias; and are said to disperse flatulencies, comfort a weak stomach, provoke the menses, and expel the stone.

GUILD, GULE, or GULEN. See GILD, and GILD.
GUILD-HALL, or GILD-HALL, the great court of judicature for the city of London.

In it are kept the *mayor's court*, the *sheriff's court*, the *court of bayliffs*, *court of cunsables*, *court of common council*, *chamberlain's court*, &c. Here also the judges sit upon *non prius*, &c.

GUILLEM, in *Ornithology*, the name given in many parts of England to the bird called by authors *LOMMIA*, and in some places the *hallow* and *foalyn*.

GUILLEMITES, an order of monks in Flanders, whose habit resembles that of the Cistercians: they follow the rule of St. Augustine, and are governed by a superior, who does not take the title of provincial, and is elected every four years.

GUILT *rents.* See **GILD.**

GUINEA, a gold coin, struck and current in England. The value, or rate, of *guineas*, has varied: it was first struck on the footing of twenty shillings; by the scarcity of gold was afterwards advanced to twenty-one shillings and six-pence; but it is now sunk to twenty-one shillings. The pound weight troy of gold is cut into forty four parts and a half; each part makes a *guinea*. See GOLD, STANDARD, and MONEY.

This coin took its denomination, *guinea*, because the gold, whereof the first was struck, was brought from that part of Africa called *Guinea*; for which reason it likewise bore the impression of an elephant.

GUINEA company. See COMPANY.

GUINEA hen, the *seductrix* of some authors and the *montana* of Linnaeus, in *Ornithology*, is the name of a species of gallinaceous fowl, of the fize of the common hen, but with a longer neck. Its body is sloped like that of a partridge, and its colour is all over a dark grey, very beautifully spotted with small white specks; there is a black ring round the neck; its head is reddish, and has on its top a hard horny protuberance of a brown colour; it is blue under the eyes, and has a red fleshy appendage hanging down from thence. The males naturally herd together in large numbers, and breed up their young in common; the females take care of the broods of others, as well as of their own. They breed very well with us. Their flesh is tender and sweet; generally white, though sometimes black.

They are not so tame and domestic as our own fowls, and particularly they will not lay in houses, but get into the hedges and among bushes, where they lay and hatch, but this is the occasion of great loss among them, the wild vermin destroying a great part of their young brood. The female also is less careful about the great business of hatching and taking care of them, than any other bird we are acquainted with: the best method, therefore, is to let other fowls upon the eggs of this kind. The young fowls of this kind are very beautiful; they have a blue and white speckled plumage, and are very red, and their whole plumage is at that time of the colour of the marriage. See *Vol. of Birds*, No. 2.

The hen, if her nest is found, and the eggs at times taken away, but so as always to have one there, will continue to lay till she has deposited a hundred, or sometimes a hundred and fifty eggs, which are very well-laid. This is a very active and spirited bird, and of an unquiet and troublesome disposition to the owner. It runs very swiftly in the manner of the quail and partridge; but its wings are short, and it is not made for flying; yet at night it will not recede among other fowl.

VOL. II. N^o 160.

but gets upon a house or tree, or any other high and safe place. The cry of the bird is sharp and disagreeable to many ears, and it is almost continually making it. It is of a quarrelsome disposition, and will be much provoked by the sight, and the appearance of its kind, generally obtain it the colony with whatever bird it fighrs. The *pitaka* is so common in America, that many have supposed it native there; but this is not the case; the origin of the bird is in Guinea, where they are found in flocks of two or three hundred, that perch on trees, and feed on worms and grasshoppers; and the first that were ever brought into America, were brought in the year 1508, with the conquest of negro slaves. The Spaniards, neither at that time, nor ever since, have attempted to tame them, or render them domestic, useful birds, but let them go loose and wild in the savannas, where they have increased to such prodigious numbers that they may well appear native, and are seen in all flocks together, and are called *pitakas* by the Spaniards and French. Observed by his Court, de l'Alle, p. 190.

GUINEA *benueid*. See *Gurra* HENWED.
GUINEA *medic*. See *Pipter*.

GUINEA-PIG, or *mus porcellus* of LINNÆUS, the name given by our common people to a sort of animal, distinguished by authors by the name of *mus porcellus palustris* or *mus*, the one with the hair and voice of a hog.

It is a creature properly of the rat kind, and is not improperly called by Mr. Ray *an American rat* (*C. agouti*), *possibly* *not* *it* *was*, the *American or Guinea rat* *with* *the* *hair* *and* *color* *of* *a* *pig*, though the same author seems to doubt whether it has not something of the rabbit kind in it, by adding after the word *most* that of *canine*. It is smaller than the rabbit, and has a shorter and thicker body, its ears are roundish, low, thin, pellucid, and very wide open, and are almost smooth; and are observed to be very nearly as large in the new-brought-forth creatures as in the full-grown.

Its nose and beard are very much like those of the hare, the long hairs which serve for whiskers being disposed in much the same manner; and its upper lip is like that of the rabbit; two cutting teeth in each jaw are disposed exactly as in the rat kind, and its hoars and grunting voice are wholly like those of the pig.

It is sometimes all over white, sometimes all over of a reddish tawney; but most frequently it is mottled with large spots of both. Its fore-feet have four claws, its hinder ones only three, of which the middle one is much longer than the others. It sits often upon its haunches, in the manner of the rabbit, but it does not walk in the leaping manner of the rabbit kind, but as the hog, by setting one foot before the other; and in walking tears upon the heel, in the manner of the bear. It does not burrow in the earth; breeds at two months old; brings forth from four to twelve young ones at a time, which are not so blind at first as in the rabbit; and breeds every two months. It feeds on vegetables, and its flesh is very well-tasted, and much resembling that of the hog. This animal inhabits Brazil, but is domesticated in Europe. Hunters are said to avoid their haunts. Ray's Syn. Quad. p. 233.

It is a very singular kind of animal, and there are three sorts of it, all different from one another. 1. The *porcellus Indicus*, or common Guinea-pig. 2. The AGUTI. And, 3. The RACA of the Americans. See also APRETA and ZOO HARE.

GUINEA *weat.* See MAIZE.
GUINEA *worm.* See CHAETIA and DRACUNCULI.

PCYNIDAE, or GYMNIDAE, i.e. *whiting*, so called on account of the whiteness of its scales, the *pinna leucocarpa* of Linnaeus, in *Lichthys*, is a name given by some to the fish known among authors by the name of *perca*, a fifth of the truttae-kind, common in the lakes of Wales, particularly in that called Llyngedig, near Bala, in Merionethshire, and some of the northern counties of England; and in the last of these places called the *schely*. It is also found in the lakes of Switzerland, Italy, Norway, Sweden, Lapland, Scotland, and Ireland. The head is small, smooth, and of a dusky hue; the eyes large, the snout blunt at the end, the jaws of equal length, the mouth small and without teeth; the branchiostegous rays nine; the cover of the gills silvery, powdered with black; the back is a little arched, the colour glossed with a deep purple and blue, but near the lateral line assumes a silvery cast tinged with gold; the side line is bright, and the scales of a fine golden hue; the bottom fin is a little prominent, and of a spiny flat at the bottom; the first dorsal fin, near the middle, consists of fourteen branched rays, the second is near the tail, and is thin and transparent; the pectoral fins have eighteen rays, the ventral twelve, and the anal fifteen, which are all branched at their ends; the tail is much forked; the scales are large, and adhere to the body.

The guinad has an insipid taste, and will not keep long.

Their spawning season in Llynged is in December. Camden observes, that this fish never wanders into the river Dee, and that the salmon never ventures into the lake: this is generally, but not universally the case. Pennant, and Phil. Trans. vol. lvi. for 1767, p. 211.

GUIRA-ACANGATARA, in *Ornithology*, the name of a Brazilian bird of the woodpecker kind, and of the size of our large spotted woodpecker. It is common in the woods in several parts of America, and like our woodpeckers, makes a very loud yelling. Marcgrave.

GUIRACENOIA, in *Ornithology*, the name of a small Brazilian bird of the parus or titmouse kind. Its head, throat, breast, belly, and the lower half of its back, are all of a fine blue; its neck and the upper half of its back black; its wings are black, variegated with blue; its tail is black, and its legs brown. Marcgrave.

GUIRACOERIBA, in *Ornithology*, the name of a Brazilian bird of the size of a greenfinch. Its head is ornamented with a large spot of sea-green feathers; the rest of its head, its throat, its breast and belly, and the lower half of its back, are of a fine shining blue, with white variegations. There runs a fine blue line across the wings. The upper half of the back is of the deepest black imaginable, and is very glossy and shining; the tail is black, and the wings are large, and have a great deal of yellow in them, but that is not seen unless when the bird is flying. Marcgrave.

GUIRA-GUINUMBI, in *Ornithology*, the name of a bird of the king-fisher or merops kind, of the size of a pigeon in appearance, being very thick covered with feathers, but its body is really not larger than that of a thrush; its bill is longish and black, a little crooked, and notched at the edges like the teeth of a saw; its legs are very short; its tail very long, and very narrow. It is a very beautiful coloured bird. Marcgrave.

GUIRANHEMGATU, in *Ornithology*, the name of a Brazilian sparrow. Marcgrave.

GUIRAPANGA, in *Ornithology*, the name of a Brazilian bird of the thrush kind, remarkable for the loudness of its voice. It is the largest of all the thrush kind, approaching to the size of a small pigeon. Its only sounds are *dit dit far far far*, which it repeats almost incessantly during the season when it cries, which is only for six or seven weeks, about midsummer. Marcgrave.

GUIRAPERA, in *Ornithology*, the name of a Brazilian bird. It is of the size of a lark, and has a short, thick, black beak; its head, neck, back, and belly, are of a pale yellow, like that of a warbler; and the lower part of the head, throat, and the breast, are black; its wings and tail are brown and black, with a slight variegation of sea-green. Marcgrave.

GUIRAGUACUBERABA, in *Ornithology*, the name of a Brazilian bird of the size of a goldfinch. Its throat and the extremity of the belly are of a fine pale yellow, as is also the back; its head, the outside of its neck, and the anterior half of its back are of a pale green, as are also its wings and tail; but the wings have some brown feathers intermixed; it has a large black spot under its throat, reaching almost to its eyes; its beak is straight, slender and pointed; its feet are brown. Marcgrave.

GUIRAQUEREA, in *Ornithology*, the name of a Brazilian bird of the caprimulgus or goat-lucker kind, a sort of small owl, approaching to the figure of the cuckoo. It is about the size of the lark, but its wings and tail are very long, which make it look much larger than it is; its legs are very short, and its toes are connected by a membrane, but not webbed like the duck. It is not said whether this be a night-bird, or one that flies by day-light; but probably it is of the first kind, as its whole figure resembles the caprimulgus. Ray's Ornithology, p. 71.

GUIRARA-NHAENGETA, in *Ornithology*, the name of a Brazilian bird of the oxenae or wheat-eat kind. Marcgrave.

GUIRATANGEIMA, in *Ornithology*, the name of a Brazilian bird of the woodpecker kind. It is of the size of a lark. There is a great deal of beauty in the contrivance of the nest of this bird; it is of a long cylindrical figure, and is very nicely built up from the firm twigs of trees. Marcgrave.

GUIRATINGA, in *Ornithology*, the name of a Brazilian bird of the heron kind, but smaller than the common heron. It walks very erect, its neck is long, and its feet and legs of a greenish yellow; it is all over of a pure fawn-white, and its neck feathers are whiter and softer than those of the ulrich. It is always seen above water. Marcgrave.

GUIRATIRICA, in *Ornithology*, the name of a Brazilian bird of the bullfinch kind, called by Mr. Ray *rahuilla americana*. It is of the size of a lark, and has a very strong beak. Marcgrave.

GUIRAUPIAGARA, in *Zoology*, the name of a species of serpent found in America, and so called from its love

of eggs, the word expressing a devourer of eggs. It is a long slender snake, black on the back, and yellow on the belly; it is a great climber of trees, and rolls about among their upper branches, as swiftly as if swimming in water; it is a great enemy to birds, destroying vast quantities of their eggs. Ray's Syn. Animal. p. 329.

GUIRON. See **GIRON**.

GUIRARRA, **GUIVAR**, in the *Indian Mule*, the name of a musical instrument of the string kind, with five double rows of strings, of which three that form the base are in the middle, and the two on the sides the burden, an octave lower than the middle.

This instrument was first brought from Spain, and the Italians give it the periodic denomination of *Spagnum*. It is found in Italy and other countries, but more frequently in Spain. The old English name of this instrument was *CETERUM*; and as the practice of it is very easy, it was formerly the recreation of lewd women and their visitors, and hence used as the symbol of a prostitute.

GUIRGUIT, in *Ornithology*, the name under which Niebuhr has described a bird which he says is no larger than a wren, and of a beautiful green colour, and much esteemed for the table. This bird, he says, has great courage, though so very small, and often attacks whole flocks of ravens, which it persecutes till they seek shelter among reeds and in thickets to hide themselves from it. Mr. Ray alleges the whole to be an entirely fabulous and false account, contrived as an imitation of the ancient tradition of the wren's fighting the eagle.

GULA, in *Anatomy*, the *OROPHAGUS* or gullet; that conduit by which animals take down food into the stomach. **GOLA** *vaginalis*. See **VAGINALIS**.

GULA, **GUEULE**, or **GOLA**, in *Architecture*, a wavy member, whose contour resembles the letter S; called by the Greeks *εὐματιον*, *eu-ma-tion*, a little wave, and by our workmen an *OGEE*. See *Arch. Vitruv.* p. 25. N° 2.

This member is of two kinds; *recta* and *inversa*. The first and principal has its cavity above, and convexity below. This always makes the top of the cornice of the cornice, jutting over the drip of the cornice like a wave ready to fall. It is called *gula recta*, and by the French *dentelle*. Sometimes it is absolutely called the *entablature*, as being the first or uppermost member thereof.

The second is just the reverse of the former, its cavity being at the bottom; so that it appears inverted with regard to the former. This is used in the architrave, and sometimes in the cornice, along with the former, only separated by a register.

Some derive the word from the resemblance those members bear to the *gula* or throat of a man; others, from the heraldic term *gules*, as supposing the moulding formed from the ancient manner of wearing their garments, which consisted of slips or swaths, alternately fur and fluff of various colours, the intervals between which were called *gules* or *guals*.

GULASISI, in *Natural History*, a name given by the people of the Philippine islands to a very small and very beautiful species of PARROT.

GULBE, in *Architecture*, the same as **CONCA**.

GULE of *August*, the day of St. Peter ad vincula, which is celebrated on the first of August.

It is called the *gule* of *August*, from the Latin *gula*, a throat, for this reason, that one Quincius, a tribune, having a daughter that had a disease in her throat, went to pope Alexander, the sixth from St. Peter, and desired of him to see the chains that St. Peter was chained with under Nero, which request being granted, and the kissing the chains, was cured of her disease: whereupon the pope instituted this feast in honour of St. Peter, and, as before, this day was termed only the calends of August; it was on this occasion called indifferently either the day of St. Peter ad vincula, from what wrought the miracle; or the *gule* of *August*, from that part of the virgin whereon it was wrought.

GULES, in *Heraldry*, signifies the colour of red.

The word is French *gules*, which Fr. Moored derives from the Hebrew *glad* or *golad*, a reddish pellice or skin appearing on a wound when it begins to heal; but F. Moondier reproaches him, that there were no such words in the Hebrew tongue. This, however, is not strictly true; all the eastern languages, the Hebrew, Chaldee, Syriac, and Arabic, say, *gula*, *glad*, for *cutis pellicis*; whence the Arabic *guled*; and in the general, the word *gula* signifies red, among most of the oriental nations: the Arabs and Persians give the name to the sole-Osney, with Nicol, derive the name *gula* from *gula*, the throats of animals being generally red; or from the Latin *calisium*, which is the name of the Greeks, of scarlet grain.

The same colour, in the coats of noblemen, is by some called *ruby*, and in those of sovereign princes, *Mars*; but this is no standing practice.

In engraving, *gules* is expressed by perpendicular strokes drawn

GUM

drawn from the top of the escutcheon to the bottom; it is also marked with the letter G. *Tab. II. Heraldry, fig. 56.*

This colour is reputed a symbol of charity, valour, hardihood, generosity, and represents blood-colour, cinnamon, and true scarlet. It is the first of all colours used in armour; and is of that account, that anciently it was prohibited any person to wear *gules* in his coat armour, unless he were a prince, or had permission from the prince.

Speelman, in his *Afropology*, says, that this colour was particularly honoured by the Romans, as it had been before by the Trojans; and that they painted the bodies of their gods, and of their generals that triumphed, with vermilion. Under the consuls, the Roman soldiers wore red, whence they were denominated *rasati*. Joan de Bado Aureo adds, that the red dye, which the Greeks call *Phenician*, and we *verlac*, was first used by the Romans, to prevent being the blood issue from wounds in fight.

In effect, *gules* has always been esteemed an imperial colour: the emperors were clothed, shod, and had their apartments furnished with red; their edicts, dispatches, signatures, and seals, were of red ink and of red wax, whence the name *verlac*.

GULL, in *Ornithology*, properly the common name of all the *LARUS* kind, but generally understood only as the name of the common black and white kind, or the *larus marinus* of Linnaeus. This is the largest of all the *gull* kind; it usually weighs between four and five pounds. Its back is yellow, flatted sideways, and three fingers breadth long, and a little hooked at the end, but the lower mandible is marked with a red spot, with a black one in the middle; its head is large and flatted at the top, and its back, breast, belly, and tail white, but with a little blackness just in the middle of the back, and in the long feathers of the wings; its legs and feet are white, and its hind toe very short; its mouth opens to a great width; it feeds on fish, and, like the raven, greedily devours carrion; it breeds in the highest cliffs, and is common on some of our coasts.

There are properly two subordine genera of these birds; the first is of those which are large, and have an even, not forked tail, and have a tubercle in the lower chap of their bill; the other of the smaller ones, which have all forked tails, and have no tubercle in the lower chap. Of the first genus are the *great gull*, the *Herring-gull*, the *sea-mall*, the *ja-mall*, the *tarbock*, the *peewit*, the *kittiwake*, the *catarract-skua*, the *martin*, the *cuddy*, the *coddy*, which Linnaeus makes synonymous with the *tarbock*, but distinguished by others; it frequents, during winter, the moist meadows in the inland parts of England, far from the sea; the *windward*, the *ceffert*, the *brave tern*, the *gavina*, and the *arctic bird* or *stront-jacquer*. And of the second or smaller kind are the *sterna*, the *fischerlin*, the *seabreeze*, and four species of the *larus fulvus*. Ray and Pennant.

GULLET. See *Oxyphagus*.

GULO. See *GLUTTON*.

GULOICEK, in *Architecture*. See *IMPOST*.

GULPH, or **GULEY**, in *Geography*, an arm or part of the ocean, running up with the land, and forming a capacious bay between two promontories.

The word comes from the French *gulf*, and that from the Italian *golfo*, which signify the same. Some deduce these farther from the Greek *gulfos*; which Gauchat again derives from the Hebrew *גול*. *gub*: Du Cange derives them from the barbarous Latin *gulfum* or *gulfus*, which signify the same thing.

Such is the *gulf* of Venice, called also the Adriatic Sea; the *gulf* of Constantinople, called the Black Sea; the *gulf* of Persia, called the Red Sea; the *gulf* of Lyons; the *gulf* of Sidra, near Barbary; the *gulf* of Mexico, of St. Lawrence, of California; the *gulf* of Bengal, and those of Cochinchina and Kamfuchoa. A *gulf* is strictly distinguished from a *sea*, because the latter is larger; from a *bay*, or *sinus* it is again distinguished, by its being greater than the same.

Some will have it essential to a *gulf*, to run into the land through a freight or narrow passage.

The sea is always most dangerous near gulfs, because of the currents being penned up by the shores.

GULYAVAN, in *Natural History*, a name given by the people of the Philippine islands to a very beautiful bird, common in that part of the world; it is of the size of a turtle dove, and is very beautifully variegated with black and gold-colored feathers. It feeds on fruits.

GUM, **GUMMI**, a mucilaginous juice, of no particular smell or taste exuding from the pores of certain plants or trees, and there hardening into a tenacious transparent mass, by the evaporation of the greater part of their superabundant water.

GUM

Gum is properly one of the juices of the bark: it is drawn thence by the sun's warmth, in form of a glutinous humour; and by the same cause, is afterwards inspissated, coagulated, and rendered tenacious.

The chemical character of *gum*, whereby they are distinguished from resins and other vegetable juices, is that they are dissoluble in water, forming with it a viscid transparent fluid; but not dissoluble in viscous spirits or oils; that they burn in the fire to a black coal, without melting or curling flame; and that they suffer no dissolution in the heat of boiling water. Of this kind of *gum* there are reckoned three kinds, viz. *gum Arabic*, *gum tragacanth*, and the ordinary *gum*, gathered from most fruit-trees, as almond, apricot, plum, and cherry, &c. But this character, it is to be observed, excludes a great part of those commonly called *gums*.

In the general, *gums* are more viscid and less friable, and are generally dissoluble in any aqueous menstruum; whereas resins are more sulphureous, and require a spirituous or oily solvent. Boerhaave considers a *gum* as a sort of saponaceous fat, which, beside its oily principle in common with a resin, has some other ingredient that renders it miscible with water.

Gum resins are juices, partly mucilaginous and partly oily, which flow from many kinds of trees, and which become concrete by the evaporation of their fluid parts. The mucilaginous and oily parts, though intimately mixed, are not absolutely combined with each other; and, therefore *gum resins* are not perfectly soluble either by water, by oils, or by spirit of wine singly: a kind of solution is effected by the aid of trituration, e. g. in water; but the resinous part remains suspended, and forms a kind of emulsion, being divided but not dissolved, whilst the *gummy* part is entirely soluble in water, and forms a mucilage with it. For the complete solution of a *gum resin*, the resinous part must be separated from the *gummy* part, by applying alternately a spirituous and a watery menstruum. All *gum resins* are combined of substances not mutually soluble by each other, and therefore the compound bodies resulting from their mixture must be opaque: all those concrete juices that are not evidently transparent, may, from hence, be reasonably suspected to be of a *gum resinous* nature: such are *myrrh*, *bellium*, *popponax*, *opopanax*, *effusatum*, &c. See *REINS*. Chem. Dict. art. *Gum*.

Grew, in his *Anatomy of Plants*, makes the following remarks concerning the import of the word *gum*, and the distinction thereof both from a *RESIN* and a *MUCI-LAGE*.

A resin, he observes, is originally a turpentine or acedulous liquor, having an exceeding small quantity of watery parts mixed therewith; and which, for that reason, will not be dissolved in water, but only in oil: of this kind are mastic, benzoin, tacamahaca, commonly called *gums*, though, strictly speaking, they are all true resins. A *gum*, on the other hand, is originally a milky liquor, having a greater quantity of water, mixed with its oily parts; and which, for that reason, dissolves either in water or oil: of this kind are *sagepans*, *opopanax*, *ammoniac*, &c.

A third sort of *gum* is that which is unctuous, and which, therefore, dissolves only in water; as *gum Arabic*, the *gum* of the cherry-tree, &c.

These last substances, though commonly called *gums*, are only dried mucilages; being originally nothing else but the mucilaginous lymph issuing from the vessels of the tree, in the same manner as it does from comfrey, mallows, &c. and even from the cucumber; the vessels thereof, upon being cut across, yielding a lymph which is plainly mucilaginous, and which, being well dried, at length becomes a kind of *gum*, or, rather a hardened mucilage.

In like manner, the *gums* of the plum-tree, cherry tree, and the like are nothing else but dried mucilages.

If we will take the word in its widest sense, all *gums* are originally either a resinous, or a milk, or a mucilage. *Gums*, in medicine, should always be strained before they are used, as being seldom free from drofs and other admixtures, which hinder their operation.

Dr. Pringle, in his *Observations on the Diseases of the Army*, tells us, that *gums* are all powerful *ANTISEPTICS*.

Theophrastus speaks of a way of multiplying plants, performed *per lachrymas*, by means of the *gum* or resin; but Agrikola takes this to be only practicable where there are seeds accidentally fallen into the *gum*.

GUM albes. See *ALOE*.

GUM amarum. See *AMMONIAC*.

GUM omne. See *AMME*.

GUM esset, in Languedoc, and some other parts of France. The juice of apples will sometimes exude through their rind, and congeal all about them in form of a clear white

gum, hard like ice, because of its being soon dried in the sun into a thin cake. The people call such an apple *jumme pice*, or a frozen apple. It is very common to see apples covered in part with this gum in several species; but it is more rare to meet with them wholly so. The gum is mixed to the taste.

We have one plant cultivated in some gardens, which yields in the heat of summer such another white, icy, and tasteless gum. This is the common rhubarb, of the stalks of the leaves of which tarts are made. The ribs of the larger leaves of this plant, in June and July, are covered with large transparent drops of this gum, and an ounce of it may be sometimes collected from a single plant. Philoz. Trans. N^o 224.

The common plants and trees in our hedges also afford the same clear and tasteless white gum. If they are wounded on purpose for it, they usually throw more or less of it out at the wound: but this is after some time, and is not in so large quantity as what they naturally throw out. The common laurel also affords a little transparent, white, and tasteless gum of no ill effect, though its leaves are poisonous. And it is seen, upon the whole, that this clear juice is not peculiar to apples, or to two or three plants only; but that a great number, even most of them, do contain it, if we knew by what means to get it from them.

GUM Arabic, called also *Thebaica*, *Serapionica*, *Babylonica*, and *Ambra*, from the places or the tree which produce it, is the juice of a little tree growing in Egypt, and also in divers parts of America, of the acacia kind, called in Latin *acacia vera*: it is very transparent, glutinous upon the tongue, almost insipid to the taste, often twisted, sometimes in the nature of a worm, and of a clear whitish or a pale yellow colour.

It is very common among us, but little is to be met with which is genuine; it is frequently adulterated with our common cherry and plum-tree gums, which are generally less white and less transparent. That is accounted best which is in smallest pieces, and almost of a white colour.

It dissolves easily in any aqueous liquor, and is used in making an aqueous vehicle for colours in painting, and for a variety of mechanical purposes: in medicine, it is good in all kinds of fluxes; particularly in catarrhs, as it thickens and softens the too acrimonious humours: it is esteemed good to incrustate, to stop the pores, blunt the points of too pungent medicines, and temper the acrimony of the trachea in coughs, &c.

It is chiefly given in the form of powder, from a scruple to a dram or two, and sometimes dissolved in water, in such proportion as not to make the liquor disagreeably slimy: an ounce renders a pint of water considerably glutinous, four ounces form the consistence of syrup. Though gum, in its dry state, is not affected by oily liquors, yet one part of gum Arabic, softened with an equal weight of water, is sufficient for rendering four parts or more of oil of balsam dissoluble. The solid resin may in like manner be reduced into emulsions, by grinding them thoroughly with powdered gum, and adding the water by degrees: by these means, all resins and oily bodies may be dissolved in watery liquors. These emulsions, as well as the simple solutions of gum in water, mingle uniformly with acids and neutral salts; but on the mixture of any alkali, their parts are immediately separated. Lewis, Mat. Med. Lond. Med. Obs. &c. vol. i. art. 28.

GUM with fetid. See *ASA-FETIDA*.

GUM kadim. See *BORLIGUM*.

GUM copal. See *COPAL*.

GUM elem. See *ELERI*.

GUM euphorbium. See *EUPHORBUM*.

GUM gussonum. See *GUAIACUM*.

GUM gatta, or gatta gatta, or ghitta gatta, popularly

gamboge. See *GAMBOGE*.

GUM lac. See *LACCA*.

GUM manna. See *MANNA*.

GUM mastic. See *MASTIC*.

GUM myrrh. See *MYRRH*.

GUM opium. See *OPIMUM*.

GUM rosmarinum. See *OROPANAX*.

GUM sapotumum. See *SAPOTUMUM*.

GUM sandarach. See *SANDARACH*.

GUM serpis draconis. See *DRAGON'S blood*.

GUM summy. See *SCAMMONY*.

GUM sicca, or jereja, is the gum ordinarily sold by the druggists for gum Arabic, which it resembles very nearly both as to form and virtue. It is either white, bordering on yellow, or of a deep amber colour, transparent, &c. It oozes out of a prickly shrub common enough in Africa, and of the same genus with that which affords the gum Arabic. The greater part of this gum is in larger and darker-coloured masses than the Arabic, and not

smooth like it, but rough on the outside. This is supposed to be the strongest and most substantial, and the Arabic the purest and finest.

The gum Senegal is chiefly employed by the callico-printers, and in other humilities where gum is made use of. A proper vehicle for water-colours in painting may be formed by mixing a third or fourth part of the gum Senegal with gum Arabic, for the former dries more slowly than the latter, which is liable to crack and separate from the canvas or parchment, on which the colour is laid with the brush and the mixture.

The gum is brought to us from Senegal, whence its name.

GUM taccamahaca. See *TACAMAHACA*.

GUM tragacanth. See *TRAGACANTH*.

GUM ului, a morbid affection of the gums, called by the writers of surgery *parulis*. These are of different degrees, and usually arise from pains in the teeth. They are to be treated by dissections as other inflammatory tumours; but if these fail, or the disorder is neglected, it usually terminates in an abscess or fistula. Sage, camomile, and elder flowers, boiled in milk and water, make a good gargism to be held in the mouth, and the remaining herbs may be fowed up in a bag to be kept hot to the cheek. A half roasted fig is a very good internal application, and when the softness of the tumor shows that the matter is suppurated, it ought immediately to be opened by the lancet, to prevent the matter's lodging there, and eroding the bone, and producing a fistula or cavity. After it is opened, the matter should be gently pressed out with the fingers, and the mouth frequently washed with red wine, mixed with a decoction of vulnerary herbs, till it is well. When the ulcer has penetrated deep, it will be necessary to inject the same liquors with a syringe, and compels the part by a proper external bandage, to make the bottom part heal first: and when it is already become fistulous, and has callous edges, it may then often be cured, by injecting tincture of myrrh and elixir propiatiat, continuing this for some time. If all these prove ineffectual, the fistula must be laid open by incision, and the caries removed by medicines, caustics, or the actual cautery. If this proceeds, as sometimes it does, from a carious tooth, this is first to be drawn before any thing else can be done; and it is a good rule in these cases always to be rather too soon than too late in laying them open. Heister.

GUM succary, chalcidilla, in Eusey, a genus of the *fungus-fungus* *agrostis* class. Its characters are these: The flower is composed of many hermaphrodite florets, which are uniform, and included in a cylindrical scaly empalement; these have one petal, which is stretched out on one side like a tongue, and they have each five short hairy filaments; the germina is situated under the floret, and becomes a single, oval, compressed seed, crowned with a single down, and included in the empalement. We have one species, which grows naturally in Germany, Helvetia, and France. Miller.

GUM, flow. See *LIQUID AMBER*.

GUM, among Gardeners, is a disease incident to fruit-trees of the stone kind, as peaches, plums, apricots, cherries, &c.

The gum is a kind of gangrene, arising from a corruption of the sap, which extravasates and hardens. It usually begins on some naked or broken part, and spreads itself to the rest. To avoid its spreading, M. QUINTINIE directs to cut off the morbid branch two or three inches below the part affected.

This gum is no more than a thick, diltempered, viscid juice, which, not being able to make its way through the fibres of the body of the tree, to feed and supply them, is obliged by the protrusion of other succeeding juice, to burst its vessels, which lie between the wood and bark, and to ooze out upon the bark.

When the distemper surrounds the branch, it admits of no remedy; and when it is only on one side of a bough, the gum must be taken off to the quick of it, and then some cow-dung clapped on the wound, and the part covered over with a linen cloth and tied down.

GUM-water. See *WATER*.

GUMMA, a sort of venereal excrecence on the periosteum of the bones.

GUMMI sive, sive gum, in the *Matéria Medica* of the ancients. We meet with this name given to a drug they sometimes used in coughs and discharges of the lungs. This was the concreted juice or exudation of the olive-tree, called by the Greeks *gummi sassa*, and by the Latins *gummi olivæ*.

GUMS, in Anatomy. See *GINGIVA* and *MOUTH*.

GUN, a fire-arm, or weapon of offence, which forcibly discharges a ball, shot, or other offensive matter, through a cylindrical barrel, by means of gunpowder.

Gun is a general name, under which are included divers, or

GUN

or even most species of fire-arms. They may be divided into *great* and *small*.

GUNS, *great*, called by the general name *cannon*, make what we also call *artillery*; under which come the several sorts of cannon, as cannon-royal, demi-cannon, &c. culverins, demi-culverins, fakers, minions, falcons, &c. See **ORDNANCE**; see also **CANNON**, **CULVERIN**, &c.

Instead of these names, which were formerly used, *great guns* are now denominated from the weight of the ball which they discharge; thus, a piece that discharges a ball of 24 pounds is called a 24 pounder; one that carries a ball of 12 pounds is called a 12 pounder, &c. and they are usually distributed into *small guns*, which consist of 42, 32, 24, 18, 12, 9, 6, and 3 pounders; *ARMED-GUNS*, *FIELD-Pieces*, and *Lighting guns*, comprehending 24, 18, and 12 pounders, whose several dimensions are as follow:

Calibre	Length	Weight
	L. I.	C. qt. lb.
24	9 8	27 0 0
18	9 0	20 1 0
12	7 8	13 2 0

With respect to the metal of which they are made, they are divided into *brass guns* and *iron guns*. See **CANNON** and **POUNDER**.

The several parts of a *gun*, see **Tab. Gunnery**, fig. 1. have peculiar names, which are as follow: *AB* represents the whole length of the *gun*, which is always reckoned from the hind part of the base-ring, or beginning of the cascable, to the extremity of the muzzle; *AE* is the first reinforce, which is that part of the *gun* next to the breech, and made stronger than the other parts for resisting the force of the powder; *EF* the second reinforce, which is made somewhat smaller than the first; *FB* is the chase; *HB* the muzzle; *A* the cascable, including the button; *b* the cascable atragal; *c* the neck of the cascable; *AC* the breech; *A* the breech mouldings; *r* the base-ring and ogee; *CD* the vent-field; *t* the vent-atragal and fillets; *f* the first reinforce atragal; *g* the first reinforce-ring and ogee; *FI* the chase-girdle; *T*, *T*, the trunnions, by which the *gun* is fixed upon its carriage; *G* the dolphins or handles; *vw* the second reinforce-ring and ogee; *a* the chafing cylinder, which is the whole piece from the chase-atragal to the muzzle-atragal; *s* the chase atragal and fillets; *m* the muzzle-atragal and fillets; *n* the swelling of the muzzle; *w* the muzzle mouldings; *e* the bore, or vacant cylinder, in which the powder and ball are lodged, the diameter of which is called the calibre, and the difference between the diameter of the shot and bore is called the windage of the *gun*; *a* the mouth; *w* the vent or touch-hole; and *c* the chamber. For a farther explication of these parts of a *gun*, see the several articles. The proportional dimensions of these parts have been differently assigned by different authors. General Armstrong, formerly surveyor-general of the ordnance, fixes them in the following manner: if the length of the *gun*, whether it be brass or iron, be divided into seven equal parts, then the length of the first reinforce, *AE*, will be two of these parts; the second, *EF*, one, and a diameter of the bore; and the chase, *FB*, four of the same parts, wanting a diameter of the bore; the breech *AC*, or distance from the hinder part of the base-ring to the beginning of the bore, is always equal to the thickness of the metal at the vent. The trunnions *T*, *T*, are always a calibre in length, and as much in diameter, clear of the second reinforce-ring, and so placed, that a line drawn through their centres touches the lower part of the bore: the length of the cascable, *AB*, is always 24 calibres. Farther, for brass *guns*, if the calibre is divided into sixteen equal parts, the thickness of metal at the base-ring from the bore is fifteen of these parts; at the end of the first reinforce ring 14.5; at the same place, for the beginning of the second reinforce, 13.5; at the end of the second reinforce 12.5; at the same place, for the beginning of the chase, 11.5; at the end of the chase or muzzle, the mouldings excluded, eight parts: as to the mouldings, the breadth of the base-ring is 1.5 inches; breadth of the next ogee two inches; from the ogee the fore-part of the atragal, a calibre; the fillets of the atragal are each .28, and the atragal .56, so that their sum is 1.12 inches; the fillets of the first and second reinforce-rings are .25, and the breadth of these rings 1.35; the ogees next to them 1.5, and the fillets at the muzzle .35. In a 12 pounder and upwards, the muzzle ogee is 1.24 inches, but in a 9 pounder, and under, only one inch; the chase-girdle and atragal is one calibre; from the mouth of the *gun* to the muzzle atragal, the space is an 18 pounder and upwards is equal to a diameter of the

GUN

second reinforce-ring, but in a 12 pounder, and under, equal to the diameter of the first reinforce-ring: the rifling of the mouldings at the first and second reinforces is an eighth of an inch; and the rifling of the base-ring is determined by laying a ruler to the extremities of the first and second reinforce mouldings. The swelling of the metal at the muzzle is always equal to the diameter of the second reinforce-ring; as to the dimensions of the cascable, the distance from the hinder part of the base-ring to the fore part of the fillet next to the button is one third of a calibre; from hence to the centre of the button, one calibre; from the hinder part of the base-ring to the hinder part of the fillet, between the two ogees, one sixth of a calibre; the diameter of the fillet next to the button 1.5 calibres; a diameter of the neck of a calibre, that of the button somewhat more than a calibre; the shell at the vent is three inches broad, and the vent is the fifth part of an inch.

For iron *guns*, the calibre is divided into fourteen equal parts, and the thickness of metal at the vent from the bore is sixteen parts, at the end of the first reinforce 14.5, at the beginning of the second 13.5, at the end of it 12.5; at the beginning of the chase 11.5, and at the end of the chase or muzzle eight parts. The mouldings, &c. are as before, excepting the vent, which is one fourth of an inch. General Armstrong makes the lengths of the several *guns* as follow, viz.

Pounders	Length	Pounders	Length
Brass gun.	feet	Iron gun.	feet
32	10	32	9.5
24	9.5	24	9
18	9.5	18	9
12	9	12	8
6	8	9	7
3	7	6	6.5
1.5	6	3	4.5

See **Muller's Artillery**, p. 70, &c.

The two following tables exhibit the dimensions of all sorts of brass and iron *guns*, as established by the Board of Ordnance in 1764.

TABLE I.

Nature	Calibre	Length	Weight	Calibre of the gun	Diameter of the shot
	Pou.	L.	W.	inches	inches
Brass gun.	42	10 0	27 0	7.3	6.68

The requisite charges for all the different pieces, on all occasions.

G U N

occasions, both in garrison and in the field, appear from the following table.

TABLE III

[illegible]

See CHARGE.

With regard to the length of guns, the modern practice is well improved; see CAUVOIS; but experiments are still wanting, in order to determine the best length for any given charge. The ancients imagined, that the greater velocity the shot had, the greater would be the effect; and therefore they made their guns long and heavy, that they might charge them with a much powder as is equal in weight to the shot. The moderns found by experience, that these guns were unwieldy, and that less force would answer the purpose; and therefore they reduced the charge of powder as well as the weight of the metal. From some experiments made by M. Du Metz, mentioned by St. Remy in his *Memoire of Artillery*, vol. I. p. 6. with pieces of different calibres, but all of the same length, viz. 10 feet, elevated to 45° , and equally charged with a quantity of powder weighing two thirds of their shot, it appears, that a 24 pounder of this length carried its shot farther with that charge than any lesser calibre of the same length; but these experiments do not prove, that, if the pieces had been longer or shorter, or if they had been loaded with more or less powder, the length of the 24 pounder was the best. To this purpose St. Remy further informs us, that pieces of the same calibre, but somewhat shorter, with half the former charge, at the same angle of elevation, ranged nearly to the same distance as the others. From some other experiments with six 24 pounders near of the same weight, whose lengths were 10.5, 10, 9.5, 9.8-5, and 8 feet, charged alike, and elevated to $7^{\frac{1}{2}}$, made by general Armstrong at Woolwich, in 1750, it has been inferred, that 9.5 was the best length for a 24 pounder; but this does not appear to be a charge as above, because, if the charge is reduced to less than the weight of the ball, it has more or less, the lengths which carried the shot farthest would likewise have been more or less: so that allowing this length to be the best for that charge, it does not follow that it will remain so when the charge is either increased or diminished, or when the weight of the metal is changed. But since these experiments were made, it has been found that eight pounds of powder are sufficient for a 24 pounder, when it is to make a breach; and therefore it remains to be determined, what is the best length for that charge.

Mr. Roberts observes, that practitioners in artillery have generally supposed, that there is one certain charge for every piece, which will communicate to the bullet a greater velocity than any other, either greater or less, and this charge has lately been assigned for heavy cannon about one third of the weight of the bullet, and for smaller pieces about one half. But from the principles which he has established, relating to the force of fired gunpowder, he infers, that every augmentation of powder will increase the velocity of the bullet, unless the charge be so great as to fill up about three eighths of the cylinder; in which case, a cleft that never occurs in practice, an addition to the charge may diminish its velocity. It has also been generally supposed, that in every species of cannon there was a certain length, which communicated to the bullet fired from it a greater velocity than could be communicated by either a longer or shorter piece; but he has shewn that if two pieces of the same bore, but of different lengths, are fired with the same charge of powder, the longer will impart the bullet with a greater celerity than the shorter; thus, in an experiment with a small piece, which was fifty fifts diameter of the bore long, and afterwards cut to twenty diameters, and charged with half the weight of the bullet in powder, he found that an iron-ball, discharged from the former, penetrated into a block of wood above half as deep again as when it was discharged from the latter; so that, within the limits of practice, there

applied to long, but if its length be augmented, an addition will be thereby made to the inferiority of its shot. We further observe, that if two pieces of artillery, differing in weight and in the metal of which they are formed, have their cylinders of equal bore, and equal length, and are loaded with like charges of powder and like bullets, they will each of them discharge their shot with nearly the same degree of celerity. However, the two pieces of the same bore, and of the same length, are exceedingly tried at the muzzle, and with the same charge of powder, the shot of the longer piece will be the fastest, with the least loss of the time of those with the longer piece, and the least resistance of the air, which accounts for the greater celerity, with different degrees of violence, the projectile move, with a greater or less velocity, and also of directing their force from the smaller calibre, which they would otherwise follow. Before, if the longer piece should discharge a heavier charge of powder than the shorter, the former will be found, provided that the charge of the shorter be not less than one-fourth of the weight of the bullet, and the charge of the longer more than the whole weight of the bullet. It appears hence, that the same piece of artillery can operate as not just measures of the velocity of the shot; and therefore a better method of determining the comparative velocities of bullets is to measure the depth of their penetration in any solid substance, placed at a small distance from the muzzle of the piece. But though the velocity of a ball may be augmented by increasing the charge or lengthening the piece, yet in many cases that occur in practice, the advantage resulting from hence are of little moment; in general, the least charges, that are sufficient to produce the desired effect in cannonading, firing against ships, raising of defences, or battering in breach, are always to be preferred; and the proper charge of any piece, whatever be its length, is not that quantity of powder which will communicate the greatest velocity to the bullet, nor is it to be determined by any invariable proportion of its weight to the weight of the ball, but it is such a quantity as will produce the least velocity necessary for the purpose, and it should be regulated by the use to which it is applied. Robins' Treatise, vol. i. p. 221. Sec. p. 236. &c. See CHARGE, GUNNERY, PROJECTION, and RESISTANCE.

TABLE of Velocities.

	12	35	18	21	14	27	30	39

$\frac{1}{4}$	1266	127	1272	1275	1278	1280	1282	1287
$\frac{1}{5}$	1578	161	1611	1612	1617	1618	1619	1621

17. B. The diameter of a mine pound foot, which is four inches, and expresses the height of the charge when it is a quarter of the weight of the foot, &c. was used in the calculation of this table. From this table it is inferred, 1. That if the charge is but a quarter of the foot's weight, the difference between the velocities, when the length is 12 and 15 diameters, is only nine feet in a second; and the differences between the other velocities decrease, as the length increases; and, therefore, as the difference between the velocities, when the piece is 15 and 30 diameters, is only twenty-two feet in a second, it follows, that when the pieces are charged with one quarter of the foot's weight, the length from 12 to 15 is the best in that case. 2. When the charge is one third of the foot's weight, it appears in the same manner, that the length from 15 to 18 diameters is the best. And, 3. When the charge is one half of the foot's weight, the length ought to be from 18 to 21 diameters; and when the charge is two thirds of the foot's weight, the length ought to be from 21 to 24 diameters; and these lengths, says Mr. Muller, are commonly to be used, for the present light field-pieces are from 12 and other 15 diameters long, and their charge is one fourth of the foot's weight; and the heavy twenty-four pounders are commonly from 21 to 24 diameters long, and their proper charge is esteemed to be two thirds of the foot's weight. On these principles Mr. Muller has given general instructions for brass and iron guns, mortars and howitzers.

howitzers, as well as of their several carriages. *Treat. of Artillery*, p. 47, &c. 95, &c.

From a table of experiments, for finding the best length of gun, and their fluek charges, deduced from actual trials in 1775, published in the *Military Dictionary*, 1779, it appears, that when the pieces were loaded with half the weight of the shot, the ranges were greater than when loaded with either more or less, except in the smaller calibres, where one third seemed to be the best charge; and the pieces of nine feet long carried farther than those of ten feet six inches, and eleven feet, &c. The advantage of large guns, or cannon, over those of a smaller bore, is generally acknowledged. This advantage, says Mr. Robins, arises from several circumstances, particularly in distant cannoning. The distance to which larger bullets fly with the same proportion of powder, exceeds the flight of the smaller ones, almost in proportion to their diameters; so that a thirty-two pound shot, for instance, being somewhat more than six inches in diameter, and a nine pound shot but four inches, the thirty-two pound shot will fly near half as far again as that of nine pounds; if both pieces are to elevated as to range to the farthest distance possible. The reason of this is, the extreme great resistance of the air, which is such, that the distances to which bullets fly is more regulated by this resistance than by the velocity they receive from the powder: and the larger bullets are less retarded, in proportion to their weight, than the smaller; so that their respective ranges are found to be nearly in the proportion of their diameters.

This advantage in the range of the heavier bullet, will not easily be counterbalanced by increasing the charge of powder allotted for the smaller bullet. For though the swiftness of this bullet, as its issuing from the piece, may be thereby greatly increased, yet the distance to which the bullet will fly is thereby but little influenced; as all this increase of velocity is soon taken away by the resistance of the air, which increases much faster. This objection might seem a paradox, but it is irrefragably established by some experiments made by the French.

Another and more important advantage of heavy bullets is, that with the same velocity they break holes in all solid bodies, in a greater proportion than their weight. Thus, a twenty-four pound shot will, with the same velocity, break out a hole in any wall, rampart, or solid beam, in which it lodges, above eight times larger than will be made by a three pound shot: for the great shot will penetrate to above twice the depth that the small one will, and less of the cavity it makes will be filled up again by the spring of the body pierced.

Large cannon also, by carrying the weight of their bullet, in grapple or load shot, may annoy the enemy more effectually than could be done by ten times the number of small pieces.

The author here quoted, has proposed to change the fabric of all the pieces employed in the British navy, from the twenty-four pounders downwards; so that they may have the same or less weight, but a larger bore. He thinks the thirty-two pounders, in present use, would be a proper model for this purpose. These being of fifty-two or fifty-three hundred weight, have somewhat less than a hundred and two thirds for each pound of bullet. And that this proportion would answer in smaller pieces, in point of strength, seems clear from these considerations: 1. That the strength of iron or any other metal is in proportion to its substance. 2. That the lesser quantity of powder, fired in a piece it fills, has proportionally less force than a larger quantity: so that if two pieces, a large and a small one, be made in the same proportions to their respective bullets, and fired with a proportionable quantity of powder, the larger piece will be more strained, will heat more, and recoil more than the smaller.

On this scheme our present twenty-four pounders will be calibred of six or eight hundred weight of solid metal; and some pieces of a less calibre, as nine and six pounders, would be sometimes used by fourteen hundred. Hence, much larger guns of the same weight might be borne. Thus, instead of six, nine, twelve, and eighteen pounders, our ships might carry twelve, eighteen and twenty-four pounders.

Guns would be kept cooler and quieter, and would be of more service in many respects, if their usual charge of powder were diminished.

The author here quoted is of opinion, from his own trials, that a much greater reduction of the weight of ship guns might safely take place, and that one fourth, and even one fifth of the weight of the bullet in powder, if properly disposed, would be sufficient for naval purposes. See Mr. Robins's Proposal for increasing the strength of the British Navy, in his *Mathematical Tracts*, vol. i. p. 283, &c. and his *Lectures*, p. 295 and 306.

The author of the *Military Dictionary*, published in 1779,

observes, with regard to the price of artillery, that the government pays 130*l.* per ton for brass cannon, 12*l.* for each horse, and a fixed price is allowed for carriages, wheels, iron-work, tumbrils, ammunition, and ball. For cannon-ball government allows 16*l.* per ton, and 8*l.* 8*s.* per quintal for gunpowder. Hence, he says, a twenty-four pounder, with its appurtenances, ready to act against an enemy, it costs the government in 32*l.* 19*s.* 5*d.* a twelve pounder in 20*l.* 10*s.* 6*d.* and a six pounder in 19*l.* 4*s.* 0*d.* *Art. Cannon.*

For the history and invention of guns, see *CANNON* and *Gunpowder*.

For the use and application of guns, see *GUNNERY* and *PROJECTILES*.

GUN, bed of. See *Bed*.

GUN, boring of. See *Boring of Cannon* and *Foundry*.

GUN, carriage of. See *CARRIAGE*.

GUN, charging of. See *CHARGE* and *GUN*.

GUN, chain. See *CHAIN* and *gun*.

GUN, evening. is generally a twelve pounder, that is fired every night about sun-set, and every morning at sun-rise, to give notice to the drums and trumpets of the army to beat and sound the retreat and the reveille.

GUNS, evolutions of. denotes the method of laying, trailing, and titing the guns, at various distances from the bat or mark: Mr. Robins recommends a more extensive exercise than that of firing with a constant charge at two or three marks, placed at known and invariable distances, in which the ranges, penetrations, and deflections of pieces, fired with all necessary diversity of charge, elevation, and distance, should be examined, and the result compared with the new principles explained under the article *GUNNERY*, &c. See *ESTIMES*.

GUN, pointing of, so as to strike distant objects, depends on two things, viz. 1. *Tracing* on the outside of the piece a visual line parallel to the axis, which is called *disparting*, and is performed by taking half the difference of the diameters of the muzzle and base-ring, and setting it perpendicularly on the muzzle-ring directly over the centre; for then a bar, which passes from that point in the base-ring, which is directly over the centre of the piece, to the extremity of the distance thus placed on the muzzle-ring, will, when the piece is truly bored, be parallel to its axis: see *DISPART* and *Line of Direction*. 2. The other operation in the determining the allowance to be made in distant shot for the incurvation of the flight of the bullet: this is greater or less (*scilicet* *parabola*) according to the different charges of powder made use of. Mr. Robins has determined, that such a charge as produces a velocity between 1100 and 1200 feet in a second, is in many cases the most eligible: supposing, therefore, that the piece is loaded with such a charge; in this case, if the shot were not retarded by the resistance of the air, the range corresponding to one degree of this piece might be reckoned 450 yards, to two degrees 900, to three degrees 1350, &c. since independently of the air's resistance, the ranges at different elevations would be nearly in proportion to their angles; at least as far as eight or ten degrees. But the resistance of the air will occasion a considerable alteration; because, by diminishing the velocity of the bullet, it will render its track more incurvated than it would otherwise be, and diminish its range: and the smaller the shot, the greater would be the diminution. The following table will serve to show the angles of elevation corresponding in different pieces to different distances, and will have the labour of computation.

Actual range in yards.	Angle of elevation.							
	34 lb.	12 lb.	9 lb.	6 lb.	4 lb.	3 lb.	2 lb.	1 lb.
1400	4 14	4 30	4 45	5 0	5 15	5 30	5 45	6 0
1200	3 26	3 40	3 50	4 0	4 15	4 30	4 45	5 0
1000	2 45	2 54	3 0	3 15	3 30	3 45	4 0	4 15
800	2 6	2 10	2 18	2 24	2 30	2 36	2 42	2 48
600	1 30	1 32	1 34	1 36	1 38	1 40	1 42	1 44
500	1 18	1 18	1 19	1 20	1 21	1 22	1 23	1 24
400	58	58	59	1	1	1	1	2
300	43	43	43	44	44	44	45	45
200	27	28	28	28	28	28	29	29
100	14	14	14	14	14	14	15	15

By this table, when the distance of the object is known, the angle, by which the axis of the piece ought to be elevated above the visual line, will be readily determined; and when this angle is known, the piece may be directed or pointed, by measuring the length of it from the middle of the base-ring to the middle of the muzzle-ring, and computing the tangent of the given angle of elevation to that radius, which may be done either by a table of tangents, or by supposing that to a radius of one foot .24 of an inch is the tangent of a degree. Let *CHRD* (Fig.

(Tab. Gunnery, fig. 8.) be the given piece, AB its axis, DE half the difference between the diameter of the muzzle-ring and base-ring, and CE the line of dispart; then make CG equal to the tangent of elevation just found, and the line GE will be the proper line for pointing of the piece. In practice it will be sufficient to erect only one perpendicular; e. g. if GC exceed DE, their difference erected on the base-ring will, with the muzzle-ring at D, give the line of direction; but if DE exceed GC, the same difference erected on the muzzle-ring will, with the muzzle-ring at C, give the direction of the piece. In distances less than 500 yards, it will be sufficient to allow one fourth of a degree for the inclination corresponding to every hundred yards, without having recourse to the table. Mr. Robins observes, that the charge of powder producing the velocity above stated is the most eligible, is from one sixth to one fourth of the weight of the bullet in powder; the different goodness of powder, and the difference in the length of pieces producing that diversity. Robins's Treatise, vol. i. p. 372, &c.

The common mechanical method of directing cannon to a given object, is to find the centre-line, or two points, one at the breech and the other at the muzzle, by a small instrument called the perpendicular, and then applying the two feet of the perpendicular to the base-centre to look behind them, till the muzzle-centre be made to cut the centre of the object; then the piece is properly directed; and having found the necessary elevation, place the centre of the quadrant in the bore, and raise or depress the piece till the plummet cuts the required elevation.

GUN, proving of. See PROVING.

GUN, rifle. See RIFLE.

GUNS, small, include fire-locks, muskets, musketoon, carbines, blunderbusses, fowling-pieces, &c. Pistols and mortars are almost the only kinds of regular weapons, charged with gunpowder, that are excepted from the denomination of guns.

No one may shoot with, or keep in his house, any hand-gun, &c. who hath not lands to the value of 100*l.* a year, on pain of 1*l.* nor shall any person shoot with such a gun, under the length of one yard, under the like penalty. If any one do so, any person who hath received an annuity, may seize the gun unlawfully kept and used; but then he must break it within twenty days, or forfeit 40*l.* In forests, parks, and chases those who have power to take away guns may retain the same. Stat. 33 Hen. VIII. cap. 6. which act continues now in force. See GAME.

Great Gun at Dover castle is a large brass gun twenty-four feet long without, and twenty-two feet in the bore beautifully adorned with flowers and emblematical figures in relief, and several inscriptions. This curious gun, vulgarly called queen Elizabeth's rocket-pistol, was a present from the emperor Charles V. to Henry VIII. while they were engaged together in a war with France. The charge of this gun is fifteen pounds of powder, and it is said to carry a ball seven or eight miles.

GUN is also a name given by the miners to an instrument used in cleaving rocks with gunpowder. It is an iron cylinder of an inch and quarter thick, and about six inches long, and having a flat side to receive the side of a wedge, and a hole drilled through it to communicate with the inside of the hole in the rock. The hole is made of about eight inches deep, and in the bottom of it is put about two or three ounces of gunpowder; then this gun is driven forcibly in, so as to fill up the hole, and the wedge is driven in on its flat side to secure it. The priming at the hole is then fired by a train, and the orifice being so well stopped by this gun, the force of the powder is determined to the circumjacent parts of the rock which it splits. See MINER.

GUN-ROOM, in a ship, is the apartment on the after end of the lower or gun-deck, where the master-gunner and his crew rendezvous, get ready their cartridges, &c. and do all their things belonging to their business. In small ships of war, it is used by the lieutenants as a dining-room, &c.

GUINELLA, in Botany, a genus of the *pentagynia* pyramidalis class. Its characters are these; it has an uniform tubulous flower, composed of many hermaphrodite flowers, which have but one petal, slightly cut into five parts; and they have five short hairy stamens; an oval germen is situated at the bottom of the flower, which becomes a roundish simple seed, inclosed in the common receptacle which is codical; and the seeds are separated by a chafy down. There are two varieties of this plant, which were discovered by (and named from) Dr. Guadalupe, in company with Mr. Tournefort, near Bibout, in Armenia. Miller.

GUNNEL of a ship. See GUN-BOAT.

GUNNELIUS, in Ichthyology. See BUTTER-FISH.

GUNNERA, in Entomology, a genus of the *gynandria diandria*

class, without calyx or corolla, and having two styles; the germen is double, dected, and contains a single seed.

GUNNERS, officers of the Tower and other garrisons, whose business it is to manage and look after the ordnance mounted on the lines and batteries, which are all fixed and ready with carriages and ball, for service, on the shortest warning.

They carry a field-flask, and a large powder-horn in a sling over the left shoulder; in which equipment they march by the guns.

GUNNER, in the *Artillery*, is the second rank of private men in the royal regiment of artillery.

GUNNER of a ship of war, is an officer appointed to take charge of the artillery and ammunition aboard; to observe that the former are kept in order, and fitted with tackle and other furniture, and to reach the sailors the exercise of the cannon: he is assisted by a mate, &c.

Master GUNNER of England, is an officer appointed to teach and instruct all such as desire to learn the art of gunnery, and to administer to every scholar an oath; which, beside the duty of allegiance, obliges him not to serve any foreign prince or state without leave; nor to teach the art of gunnery to any but such as have taken the said oath; and to certify to the master of the ordnance, the sufficiency of any person recommended to be one of his majesty's gunners.

The *gunner*, Sir J. Moore observes, should know his pieces and their names, which are taken from the height of the bore, the names of the several parts of a piece of ordnance, how to terrate his gun, and how to dispart it, &c.

GUNNER's level. See LEVEL.

GUNNERY, the art of shooting with guns and mortars, i. e. of charging, directing, and exploding those fire-arms to the best advantage. See Tab. Gunnery, fig. 9.

Gunnery is sometimes considered as a part of the military art, and sometimes as a part of pyrotechny.

To the art of gunnery belongs the knowledge of the force and effect of gunpowder, the dimensions of pieces, and the proportions of the powder and ball they carry, with the methods of managing, charging, pointing, spunging, &c.

Some parts of gunnery are brought under mathematical consideration, which, among mathematicians, are called absolutely by the name *gunnery*; viz. the method of elevating or raising the piece to any given angle, and of computing its range, or of finding or directing it so, as it may hit a mark or object proposed.

The instruments chiefly used in this part of gunnery are the *quadrant* or *gunner's compass*, *quadrant*, and *level*; the methods of applying which, see under those articles; and for the particular principles and laws of gunnery, see PROJECTILE.

With regard to the history of this part of mixed mathematical science we may observe, that long before the invention of gunnery, properly so called, the art of artillery was in actual practice for one of the kings of Judah, eight hundred years before the Christian era, erected, on the towers and bulwarks of Jerusalem, engines of war, for shooting arrows and great stones for the defence of that city. 2 Chron. xxvi. 15.

Such machines were afterwards known to the Greeks and Romans under the names *BALLISTA*, *CATAPULTA*, &c. which produced effects, by means of the action of a spring of a strongly twisted cordage, formed of tough and elastic animal substances, no less terrible than the cannon and mortars of the moderns. These warlike instruments continued in use, not only during the time of the Roman empire, but to the twelfth and thirteenth centuries; nor is it probable that they were totally laid aside, till gunpowder and the modern ordnance superseded their use.

The first application of GUNPOWDER to military affairs seems to have been soon after the year 1300, for which the proposal of friar Bacon, about the year 1280, for applying its enormous explosion to the destruction of armies, might give the first hint; and Schwartz, to whom the invention of gunpowder has been erroneously ascribed, might have been the first who actually applied it in this way: for, it is said, that having pounded the materials of this mixture in a mortar, which he afterwards covered with a stone, a spark of fire accidentally flew into the mortar, and the explosion blew the stone to a considerable distance.

We shall here only mention the prohibition of fire-arms in the Code of Genoa Laws, printed by the East India Company in 1776, which seems to confirm the supposition suggested by a passage in Quintus Curtius, that Alexander the Great found some weapons of that kind in India. Cannon in the *Scythian* idiom; is called *ter-aghins*, or the weapon that kills a hundred men at once.

However, the first pieces of artillery, charged with gunpowder

powder and stone bullets of a prodigious weight, were of very clumsy and inconvenient size and structure. See CANNON. Thus, when Mahomet the Second besieged Constantinople in 1453, he battered the walls with stones of this kind, and with pieces, some of which were of the calibre of 1200 pounds, and which could not be fired more than four times a day. The matter and fabric of these unwieldy pieces were changed for others that were lighter and more manageable, and particularly for brass cannon, about the close of the fourteenth century. The formation of artillery, if we except the ingenious method of boring cannon, not long since invented, hath been little improved within the last two hundred years; the proportions of the best pieces being now much the same with those that were made in the time of the emperor Charles V. but their use and application have undergone considerable changes, the same ends being now generally pursued by smaller pieces than those which were formerly thought necessary: the manner of forming a breach, by first cutting off the whole wall as low as possible, before its upper part is attempted to be beat down, seems also to be a considerable improvement in the practical part of artillery, as is also that disposition of artillery called the BATTERY à ricochet, first used in 1692. But the theory of gunnery has made slower advances than the mechanical part. The first people who directed their attention to this subject were the Italians, about the beginning of the sixteenth century. N. Tartaglia, the famous mathematician of Brescia, who invented the method of solving cubic equations, generally ascribed to Cardan, professedly dissuaded the theory of projectiles, in his *Nova Scientia*, printed at Venice in 1537; and in his *Questi & Iuventuti diversi*, in 1546; and in another work, translated into English, under the title of *Colloquies concerning the Art of Shooting in great and small Pieces of Artillery*, and published at London in 1588: he is supposed to be the first who asserted, that the greatest range of projectiles was at an elevation of 45° ; and he also determined, contrary to the opinion of his contemporaries, that no part of the track described by a cannon-ball is a right line, though the curvature is in some cases so small as not to need attention. To him is likewise ascribed the invention of the *gunner's quadrant*.

However, nothing decisive was delivered as to the nature of the curve described by such bodies till the time of Galileo, who discovered the law of ACCELERATION in falling bodies, and published his celebrated *Dialogues on Motion* in 1638. He described the action and effects of gravity on falling bodies, and on these principles determined, that the flight of any projectile would be in the curve of a parabola, unless so far as it were diverted from that track by the resistance of the air: accordingly he has shown, that a body, shot horizontally, would, in its flight, describe half a parabola, and when the piece had an elevation above the horizon, a whole parabola, provided that it fell on the plane of the battery: he also proved, that, whatever the ranges of the projected body or the elevation of the piece were, the ball would still trace that curve line, of a greater or less amplitude, by the time it descended to the level of the place from which it was projected. His disciple, Torricelli, extended this theory, by shewing that, whether the ball fell above or below the plane of its projection, it described a parabola of a larger or a smaller amplitude, according to the angle of elevation of the piece and the strength of the powder. Galileo was not surprised of the effects of the air's resistance, and he has proposed the means of examining the inequalities which they would occasion in the motion of a ball at some given distance from the piece: yet he expressly says, that "among these projectiles which we make use of, if they are of a heavy matter and round form, say, if they are of a lighter matter, and have a cylindrical form, such as arrows shot from bows, their track or path will not sensibly decline from the curve of a parabola." See his fourth *Dialogue on Motion*. In this theory his successors for a considerable time acquiesced, without trying how far the real motions of projectiles deviated from a parabolic track, or deciding, whether the resistance of the air was, or was not, necessary to be attended to in the determinations of gunnery. Admitting that no great variation could arise from the resistance of the air, in the flight of balls, chiefly on account of the extreme rarity of the air compared with the dense and ponderous composition of those projected bodies, they established it as a kind of general axiom, that the flight of these bodies is nearly in the curve of a parabola. Accordingly, in 1674, our countryman, Mr. Anderson, published his treatise of the Genuine Use and Effects of the Gun, in which he maintains the Galilean theory, and to answer all objections that could be urged against it: and though he was obliged to infer

from subsequent experiments, that the whole track of projected bodies was not parabolic, as appears by his treatise, entitled *To hit a Mark*, published in 1690, yet, instead of ascribing the deviation of their flight from the parabolic curve to the resistance of the air, he framed an hypothesis for reconciling his experiments with his doctrine: he supposed, that the bullet, at its first discharge, flew far a certain distance in a right line, from the end of which line it began to bend into a parabola: this right line, which he calls the *line of the impulse of fire*, he supposes to be the same in all elevations; and, by assigning a proper magnitude to this line of impulse, he was able to reconcile any two shot made at different angles, however opposite they might prove to the common principles. But this new-moulded theory was not confirmed by his following experiments.

In the year 1683, Mout. Blondel published, at Paris, a treatise, entitled *L'Art de jeter des Bombes*, in which he labours to shew, that the retardation arising from the resistance of the air is so very inconsiderable, as to be of no account in practice. This opinion was so generally received both in France and England, that there seem to have been none who suspected its fallacy.

Dr. Halley, in a paper communicated to the Royal Society in 1686, expressly asserts, that "in large shot of metal, whose weight many times surpasses that of the air, and whose force is very great in proportion to the surface wherewith they press thereon, this opposition (occasioned by the resistance of the air to the motion of cannon-balls) is scarce discernible;" and from actual experiments he infers, that "although in small and light shot the opposition of the air ought and must be accounted for, yet in shooting of great and weighty bombs, there need be very little or no allowance made." *Phil. Trans.* N° 179, p. 16, or *Abr.* vol. i. p. 484.

The practitioners in gunnery, though an erroneous theory had obtained the sanction of so great a name as that of Dr. Halley, might have been led to suspect its truth by the authority of a still greater name, viz. that of Sir Isaac Newton, who, in 1687, published his *Principia Mathematica*. *Phil. Nat.* in which he has demonstrated, (see lib. ii. § 7.) that the curve described by a projectile, in a strongly resisting medium, differed much from a parabola, and that the resistance of the air was great enough to make the difference between the curve of projection of heavy bodies and a parabola far from being insensible, and, therefore, too considerable to be neglected. The truth of these conclusions was farther established by M. Huygens, in his *Discours de la Cause de la Peinture*, Leide, 1690, in which he asserts, from experiments and mathematical investigation, that the track of all projectiles was very different from the line of a parabola. However, the testimony of these writers produced little change in the general opinion; indeed M. Reason, a French officer of artillery, in a memoir presented to the Royal Academy, in 1716, declares that theory was of very little service in the use of mortars; that practice had convinced him there was no theory in the effects of gunpowder; for, having endeavoured, with the greatest precision, to point a mortar agreeably to the calculations of M. Blondel, he had never been able to establish any solid foundation upon them. One other instance occurs, in which D. Bernoulli applies the doctrine of Sir Isaac Newton to the motions of Projectiles. *Com. Acad. Petrop.* tom. ii. p. 338, &c.

In this state of error and unaccountable contradiction between theory and practice did the science of gunnery remain, till the ingenious Mr. Robins, in the year 1742, published a small treatise, entitled *New Principles of Gunnery*, containing many curious discoveries relating to the force of gunpowder, the velocity of bullets impelled by its explosion, the difference in the resisting power of the air to swift and slow motions, the deviation of the flight of projected bodies from the parabolic curve in a degree never discovered or suspected by any, and the deflection of bullets and other projectiles from the vertical plane in which the shot is made, resulting from a rotary motion which they accidentally acquire about an axis. These discoveries have been confirmed and improved by himself in subsequent publications, and by others, particularly M. Euler, of Berlin, who published it with a large Commentary, in 1745; and by M. Le Roy, of Paris, in the *Mém. Acad. Sc.* for 1751; and by Dr. Hutton, of the Military Academy at Woolwich. The reader will find a more particular account of these discoveries in the sequel of this article, and under the articles GUN, GUNPOWDER, PROJECTILE, RANGE, RESISTANCE, and RIFLE &c.

Mr. Robins, from the experiments related in his *New Principles of Gunnery*, having concluded, that the force of fired GUNPOWDER, at the instant of its explosion, is the same as that of an elastic fluid of a thousand times

the density of the common air, and that the elasticity of this fluid, like that of air, is proportionable to its density, propose the following problem.

The dimensions of any piece of artillery, the density of its ball, and the quantity of its charge being given, to determine the velocity which the ball will acquire from the explosion, supposing the elasticity or force of the powder at the first instant of its firing to be given.

In the solution of this problem he assumes the two following principles: 1. That the action of the powder on the ball ceases as soon as the bullet is got out of the piece. 2. That all the powder of the charge is fired, and converted into an elastic fluid, before the bullet is sensibly moved from its place.

These assumptions, and the conclusions before mentioned, make the action of fired gunpowder to be exactly similar to that of air condensed a thousand times, and from thence it will not be difficult to determine the velocity of the ball arising from the explosion; for the force of the fired powder diminishing in proportion to its expansion, and ceasing when the ball is out of the piece, the total action of the powder may be represented by the area of the curve, the base of which represents the space through which the ball is accelerated; and the ordinates to which, represent the force of the powder at every point of that space; and these ordinates being in reciprocal proportion to their distance from the breech of the gun, because when the spaces occupied by the fired powder are as 1, 2, 3, 4, &c. the force of the powder, or the ordinates representing it, will be as 1, $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c. it appears that the curve will be a common hyperbola, and that the area intercepted between it, its asymptote, and the two ordinates representing the force of the powder at the first explosion and at the muzzle of the piece, will represent the total action of the powder on the ball; but if the ball were urged through the same space by an uniform force equal to its gravity, the total action of this force would be represented by a rectangle, the base of which would be the base of the curve or intercepted portion of the asymptote before mentioned, and the height of which would represent the uniform force of gravity. Hence the square of the velocity of the ball, resulting from the action of the gunpowder, will be to the square of the velocity, resulting from the action of gravity, as the area of the hyperbolic space is to the area of the rectangle; but the velocity of the ball resulting from gravity is given, being the velocity it would acquire from a height equal to the space through which the powder accelerates it; and the proportion between the hyperbolic space and the rectangle is also given from the analogy of hyperbolic spaces and logarithms; therefore the velocity of the ball arising from the action of the fired gunpowder will be given. This reasoning may be illustrated by a view of fig. 10. *Tab. Gunar.* to which let AB represent the axis of any piece of artillery, A the breech, and B the muzzle; DC the diameter of its bore, and DEGC a part of its cavity filled with powder. Suppose the ball, that is to be impelled, to lie with its hinder surface at the line GE, then the pressure exerted at the explosion, on the circle of which GE is the diameter, or, which is the same thing, the pressure exerted in the direction FB, on the surface of the ball, is easily known from the known dimensions of that circle: draw any line FH perpendicular to FB, and AI parallel to FH, and through the point H, to the asymptotes IA and AB, describe the hyperbola KHNO; then if FH represents the force impelling the ball at the point F, the force impelling the ball in any other place as M will be represented by the line MN, the ordinate to the hyperbola at that point; for when the fluid impelling the body along, has dilated itself to M, its density will be then to its original density in the space DEGC reciprocally as the spaces through which it is respectively extended; that is, as FA to MA, or as MN to FH, but it appears, that the elasticity or impelling force of this fluid is directly as its density; therefore, if FH represents that force at the point F, MN will represent the like force at the point M.

Since the absolute quantity of the force impelling the ball at the point F is known, and the weight of the ball is likewise known, the proportion between the force the ball is impelled with, and its own gravity, is known. In this proportion take FH to FL, and draw LP parallel to FB: then MN, the ordinate to the hyperbola in any point, will be to its part MR, cut off by the line LP, as the impelling force of the powder in that point M, to the gravity of the ball; and consequently, the line LP will determine a line proportional to the uniform force of gravity in every point; whilst the hyperbola HNQ determines in like manner such ordinates, as are proportional to the impelling force of the powder in every

point; whence, by the 35th proposition of lib. 1. of Sir Isaac Newton's *Phil. Nat. Prin. Math.* the areas FLPB and FHQB are in the duplicate proportion of the velocities, which the ball would acquire, when acted on by its own gravity through the space FB, and when impelled through it, the same space by the force of the powder. But since the ratio of AF to AB, and the ratio of FH to FL are known, the ratio of the area FLPB to the area FHQB is known; and since in the duplicate, And since the line FB is given in magnitude, the velocity, which a heavy body would acquire in falling through this line by its own gravity, is known, being no other than the velocity it would acquire by falling through a space equal to that line; find then another velocity, to which this ball mentioned velocity bears the given ratio of the duplicate of the area FLPB to the area FHQB, and this velocity, thus found, is the velocity the ball will acquire when impelled through the space FB by the action of the inflated powder.

To give an example of this, let us suppose the length of the barrel of a gun, or AB, to be 45 inches, its diameter DC, or rather the diameter of the ball to be $\frac{1}{2}$ of an inch, and the space occupied by the powder, A.F. to be 25 inches; to determine the velocity which will be communicated in a leather bullet by the explosion, supposing the bullet laid at rest with its surface contiguous to the powder.

By the theory here laid down it appears, that at the first instant of the explosion the flame will exert, on the ball lying close to it, a force one thousand times greater than the pressure of the atmosphere, &c. But the mean pressure of the atmosphere is estimated equal to that of a column of water 32 feet high; whence lead equal to water as 11:245 to 3, this pressure will be equal to that of a column of lead 3460 inches in height, whence multiplying this by 1000, a column of lead 3460000 inches high would produce a pressure equal to what is exerted on the ball by the powder in the first instant of the explosion; and the leaden ball being $\frac{1}{2}$ of an inch in diameter, and consequently equal to a cylinder of lead on the same base 1 an inch in height, the pressure at first acting on it will be equal to $\frac{3460000}{2}$ or 1730000 times its weight; whence the force of gravity, FL, is to that of the powder at its first explosion, FH, as 1 to 698000; and FH to FA is as 45-25 (or 45) to 2; that is, as 330 to 211; whence the rectangle FLPB is to the rectangle FHQB, as 330 to 211 x 698000 that is, as 1104224. And from the known application of the logarithms to the determination of the hyperbolic space it follows that the rectangle AFHS is to the area FHQB as 43449. Sec. is

to the tabular logarithm of $\frac{AB}{AF}$; that is, of $\frac{45}{25}$, which is 1.255279, whence the ratio of the rectangle FLPB to the hyperbolic area FHQB is compounded of the ratio of 1 to 43449, and of .43449, Sec. to 1.255279; which together make up the ratio of 1 to 1220.3; the subduplicate of which is the ratio of 1 to 35.07; and in this ratio is the velocity, which the bullet would acquire by gravity, in falling through a space equal to FB, to the velocity the bullet will acquire from the action of the powder, impelling it through FB, but the space FB being 42 inches, the velocity a heavy body will acquire in falling through such a space is known to be, what would carry it nearly at the rate of 1507 feet in $\frac{1}{4}$ of time; whence the velocity, to which this has the ratio of 1 to 35.07, is a velocity, which would carry the ball at the rate of 1507 x 35.07 feet in $\frac{1}{4}$ of time; that is, at the rate of 168 feet in $\frac{1}{4}$ of time. And this is the velocity, which, according to the theory, the bullet in the present circumstances would acquire from the action of the powder, during the time of its duration. And this being once computed for one case, is easily applied to any other; for if the cavity DEGC be behind the bullet be only in part filled with powder, then the line H.F. and consequently the area FHQB will be diminished in the proportion of the whole cavity to the part filled; if the diameter of the bore be varied, the lengths AB and AF remaining the same, then the quantity of powder and the surface of the bullet which it acts on, will be varied in the duplicate proportion of the diameter; but the weight of the bullet will vary in the triplicate proportion of the diameter; whence the line FH, which is directly as the absolute impelling force of the powder, and reciprocally as the gravity of the bullet, will change in the reciprocal proportion of the diameter of the bullet. If AF, the height of the cavity left behind the bullet, be increased or diminished, the rectangle of the hyperbola, and consequently the area corresponding to ordinates in any given ratio, will be increased or diminished in the same proportion. From all which it follows, that the area FHQB, which is in the duplicate

duplicate proportion of the velocity of the impelled body, will be directly as the logarithm $\frac{A \cdot B}{A \cdot C}$, (where A & B represent the length of the barrel, and $A \cdot C$ the length of the cavity left behind the bullet,) also directly as the pressure that cavity filled with powder, and inversely as the diameter of the bore, or rather of the bullet, likewise directly as $A \cdot F$ the height of the cavity left behind the bullet. Consequently the velocity being computed above, for a bullet of a determined diameter, placed in a piece of a given length, and impelled by a given quantity of powder, occupying a given cavity behind that bullet, it follows, that by means of their ratio the velocity of any other bullet may be thence deduced, the necessary circumstances of its position, quantity of powder, &c. being given. Where note, that in the instance of this proposition we have supposed the diameter of the ball to be 2 of an inch: whence the diameter of the bore will be something more, and the quantity of powder contained in the space DRGC will amount to exactly 12.266, a small wall of iron included.

As to the full of the principles here assumed, the author has omitted (for also his Mathematical Tracts, vol. i. p. 164, &c.) that it would be found erroneous, if examined with a geometrical rigour; since it cannot be questioned but the same acts in some degree on the bullet after it is out of the piece: but, in experiments, no such accuracy is attainable; hence irregularities are the necessary concomitants of all complicated experiments: in the collision of bodies, in the running or spouting of water, even in small velocities, irregularities happen, not reconcilable to theory, or to each other; what may not then be supposed to happen from the action of so furious a power as gunpowder? From experiments it appears, that velocities of bullets fired from the same piece, charged with the same powder, and all other circumstances, as nearly as possible the same, do yet differ from each other by sometimes more than $\frac{1}{2}$ part of the whole; but this is a small degree of inaccuracy in a case of this nature, and if the action of the flame on the bullet, after it is out of the piece, is so small as to produce no greater effect than what may be destroyed by the inevitable variations of the experiments, the neglecting it entirely is both convenient and a reasonable procedure. Now, what gives ground to think that this pollution, though not rigorously strict, may be safely assumed, is the consideration of the spreading of the flame by its own elasticity, as soon as it escapes from the mouth of the piece; for by this it may be conceived that the part of it which impinges on the bullet may be neglected, although the impulse of the flame be a very remarkable force.

With regard to the second assumed principle, that all the powder is fired before the bullet is sensibly moved from its place, it is to be observed, that this very position, having been examined by a committee of the Royal Society, was, after several experiments, determined in the negative, from whence many may be ready to conclude, that the whole theory must be overturned. But this requires a farther discussion, and it will appear, that though this principle be not rigorously true, no more than the former; yet it seems also that it may be safely admitted in investigating the effects of powder, since, even in short barrels, where the force the bullet was impelled through was not five inches, and where of course the deficiency of velocity was great, it cannot amount to one third part of the whole. This will appear from the experiments made by the committee; for when the barrel was so shortened, that the bullet being placed close to the wall, lay with its outer surface nearly level with the mouth of the piece, yet, even in this short transit of the bullet, but for the whole charge, as a medium, was collected unfired, which, properly reduced, amounts to but $\frac{1}{2}$ of the charge. This reduction is founded on these considerations, that the powder used by the committee being unequally grained, when the smaller grains, collected by sifting, were used, the quantity remaining unfired was less at a medium, in the ratio of 5 to 3, than when it was used without sifting. Also, by extracting the full-petre from the powder collected unfired, there was less full-petre contained in it than in real powder, nearly in the ratio of 9 to 7. Now these two proportions compounded, make the proportion of 15 to 7, in which proportion, must the quantities of powder unfired be reduced, in order to determine the quantity of fine good powder that might be supposed to remain unfired in the experiments brought to confirm the foregoing theory.

Now, it appears, by experiments, that the velocities of bullets placed in the same situation, are in the subduplicate proportion of the charges; consequently the deficiency of velocity arising from the loss of $\frac{1}{2}$ of the

charge will be about $\frac{1}{4}$ of the velocity only. And in the experiments made with a barrel 53 inches in length, where the ball had not three inches to move, the quantity of real powder collected unfired from a charge of 13.266, would have been no more than 16 grains, at a medium, or $\frac{1}{4}$ of the whole charge, which would produce a deficiency of $\frac{1}{4}$ of the velocity only: a difference less than what frequently occurs in the exact repetition of the same experiments.

This, it is thought, is fully sufficient to justify the principle in question; especially, as in all cases of real use, the length of the barrel, in proportion to the quantity of the charge, will be much greater than in the instances here mentioned. See Phil. Trans. N° 469 p. 452, 453, &c. or Martyn's Abr. vol. viii. p. 268, or Robins's Math. Tracts, vol. i. p. 164, &c. and see the Experiments of the Committee, in the Transactions, N° 462 p. 172, 173, &c. or Martyn's Abr. vol. viii. p. 253, &c.

The greatest number of those who have written on the manner in which powder takes fire, have supposed it to be done by regular degrees; the full grains firing those contiguous, and they the next successively; and it has been generally thought, that a considerable time was employed in these various communications: for Mr. Daniel Bernoulli, in his Hydrodynamica, has concluded, from some experiments made at Peterburgh, that the greatest part of the charge escapes out of the piece unfired, and that the small part which is fired, does not take fire till it is near the mouth. Many theories too have been composed on the time of the progress of the fire among the grains, and the different modifications which the force of powder did them receive; and it has been generally conceived, that the proper lengths of pieces were determinable from this principle; so that they should be long enough to give time for all the powder to fire.

But no such regular and progressive steps from observable in the explosion. For considering that by doing with a greater weight of bullet, and thereby almost doubling the time of the continuance of the powder in the barrel, its force receives but an inconsiderable augmentation; and that doubling and tripling the usual charge, the powder thus added always produces a correspondent effect in the velocity of the bullet; likewise, that in a piece near four feet in length, charged with an usual charge of powder, the velocity communicated to the bullet, during the first three inches of its motion, is full half the velocity acquired in its whole passage through the barrel; and considering also that the elasticity or force of the powder, in the three first inches of its expansion, is at a medium near eight times greater than in the two last feet of the barrel: it may be concluded from all these circumstances, that the time employed by the powder in taking fire was not necessary to be attended to in their computations; but that the whole mass might be supposed to be kindled, before the bullet was sensibly moved from its place.

And the experiments reported by the committee of the Royal Society, before mentioned, are strong proofs that the powder is not fired in the progressive manner usually supposed; for when the short barrel was charged with twelve penny-weight and six penny-weight respectively, the quantity of powder which was collected unfired from twelve penny-weight, did not exceed by three grains, at a medium, what was collected from six penny-weight, although the bullet was a less time in passing through the barrel with twelve penny-weight than with six, it having a less way to move; consequently the quantity remaining unfired of the six penny-weight, did not continue unfired for want of time, since when the piece was charged with twelve penny-weight, the additional six penny-weight was consumed in a shorter time. See Phil. Trans. N° 469 p. 450, or Robins, &c. ubi supra.

Mr. Robins has also given us an ingenious way of determining, by experiments, the velocity which any ball moves with, at any distance from the piece it is discharged from.

This may be effected by means of a pendulum made of iron, having a broad part at bottom, covered with a thick piece of wood, which is fastened to the iron by screws. Then having three poles joined together by their tops, and spreading at bottom, such as are vulgarly used in weighing and lifting heavy bodies, and called by workmen triangles; on two of these poles, to which their tops are secured on sockets, on which the pendulum is hung by means of a cross-piece, which becomes its axis of suspension, and on which it ought to vibrate with great freedom. Something lower than the bottom of the pendulum there should be a brace, joining the two poles to which the pendulum is suspended; and to this brace there is fastened a contrivance made of two edges of steel, something in the manner of a drawing pen; the strength with which these edges press on each other being diminished or increased at pleasure, by means of a screw. To

the bottom of the pendulum should be fastened a narrow ribbon, which passing between the steel edges, may hang loosely down by means of an opening cut in the lower piece of steel.

The instrument being thus fitted, if the weight of the pendulum, the respective distances of its centre of gravity, and of its centre of oscillation from its axis of suspension, be known, it may from thence be found what motion will be communicated to this pendulum by the percussion of a body of a known weight moving with a known degree of velocity, and striking it in a given point; that is, if the pendulum be supported at rest before the percussion, it will be known what vibration it ought to make in consequence of such a blow; and if the pendulum being at rest, is struck by a body of a known weight, and the vibration which the pendulum makes after the blow is known, the velocity of the striking body may from thence be determined.

Now the extent of the vibration, made by the pendulum, may be measured by the ribbon. For if the pressure of the steel edges on the ribbon be regulated by the screw, so as to be free and easy, though with some minute resistance to hinder its slipping of itself, then setting the pendulum at rest, let the part of the ribbon between the pendulum and steel edges be drawn straight, but not strained; and fixing a pin in the part of the ribbon contiguous to the edges, the pendulum swinging back by the impulse of the ball, will draw out the ribbon to the just extent of its vibration, which will be determined by the interval on the ribbon between the edges and the place of the pin.

The computation by which the velocity of the ball is determined, from the vibration of the pendulum after the stroke, is founded on this principle of mechanics: that if a body in motion strikes on another at rest, and they are not separated after the stroke, but move on with one common motion, then that common motion is equal to the motion with which the first body moved before the stroke; whence, if that common motion and the masses of the two bodies are known, the motion of the first body before the stroke is thence determined. On this principle it follows, that the velocity of a bullet may be diminished in any given ratio, by its being made to impinge on a body of a weight properly proportioned to it; and hereby the most violent motions, which would otherwise escape our examination, are easily determined by the retarded motions which have a given relation to them. See *New Princip. of Geometry*, p. 25, 30, &c. See also the *Phil. Trans.* N^o 469, p. 444, where a small correction, relating to a number in Mr. Robins's 8th proposition, is mentioned; or *Math. Tracts*, vol. i. p. 83, &c. and p. 163, &c.

It is to be observed, that the length to which the ribbon is drawn, is always nearly the chord of the arch described by the ascent, it being so placed, as to differ insensibly from those chords which most frequently occur; and these chords are known to be in the proportion of the velocities of the pendulum acquired from the stroke. Hence it follows, that the proportion between the lengths of ribbon drawn out at different times, will be the same with that of the velocities of the impinging bullets.

Now from the computations delivered by Mr. Robins, it appears, that the velocity of a bullet, whose weight was $\frac{1}{12}$ of a pound, was 1641 feet in one second of time, when the chord of the arch described by the ascent of the pendulum, in consequence of the blow, was 171 inches. Therefore, by the proportion of any other length of ribbon drawn out, by any percussion, to 171, the proportion of the velocity with which the bullet impinged, to the known velocity of 1641 feet in $\frac{1}{12}$, will be determined.

As experiments of this kind are often attended with danger and difficulty, those who may be disposed to make any, will find several useful practical cautions, in p. 31, 32, and 33, of the said treatise.

By the experiments recited at large, in proposition IX. of the same treatise, it appears, that the computations from Mr. Robins's theory, compared with those experiments which were made with barrels of various lengths, from seven inches to forty-five, and with different quantities of powder, from six penny-weight to thirty-six, have a remarkable coincidence, and such as occurs but in a few philosophical subjects of so complicated a nature.

Supposing, for instance, the length of a barrel to be 43 inches, the quantity of powder 12 penny-weight, the cavity containing it 21 inches, and the ball $\frac{1}{12}$ inch diameter, weighing 12 ounce, or $\frac{1}{12}$ of a pound avoirdupois, and the windage or excess of the diameter of the barrel above that of the bullet about $\frac{1}{16}$ of an inch; the velocity of the bullet will, by theory, be about 1670 feet in one second, and this velocity is found in these experiments, to be the mean velocity which the ball really receives in those circumstances. Hence we may determine

the velocities with which musket and cannon-shot are discharged from their respective pieces, by their usual allotment of powder.

For as a leaden ball of $\frac{1}{12}$ inch diameter, and weighing nearly 12 ounce avoirdupois, being fired from a barrel of 43 inches in length, with half its weight of powder, will have a velocity at its issuing from the piece, which, if uniformly continued, would carry it near 1706 feet in $\frac{1}{12}$; so if instead of a leaden ball an iron one of the same diameter was placed in the same situation in the same piece, and was impelled by the same quantity of powder, the velocity of such an iron bullet would be greater than that of the leaden one, in the subduplicate ratio of the specific gravities of lead and iron; and supposing that ratio to be as 3 to 2, and computing on the foregoing principles, it will appear, that an iron bullet of 24 lb weight, shot from a piece of ten feet in length, with 16 lb of powder, will acquire from the explosion a velocity which, if uniformly continued, would carry it nearly 1650 feet in $\frac{1}{12}$. But if instead of this full charge, weighing two thirds of the ball, we suppose the charge to be only half that weight, then its velocity would be no more than at the rate of 1450 feet in $\frac{1}{12}$; and the same would be the velocities of every lesser bullet, fired with the same proportions of powder, if the lengths of all pieces were constantly in the same ratio with the diameters of their bore; and though this proportion does not always hold, yet the difference is not considerable enough to occasion a very great variation from the velocities here assigned. But in these determinations, the windage is supposed to be no more than is just necessary for the easy passing down the barrel; whereas, in real service, either through negligence or unskillfulness, it often happens, that the diameter of the bore so much exceeds the diameter of the bullet, that great part of the inflated fluid escapes by its side; whence the velocity of the shot may, in this case, be considerably less than what is here assigned: however part of this may possibly be compensated by the greater heat which in all probability attends the firing these large quantities of powder.

The theory here established supposes what is said under the head GUN-POWDER, that the powder when fired is equally hot with iron at the beginning of its white heat; but in very small quantities of powder the heat is probably less, and consequently the elasticity less than what arises from this supposition. Now this decrease of elasticity in small quantities of powder has been found in many trials actually to take place. For instance, according to the theory before laid down, the velocity given the ball by the action of the powder, is in round numbers 1670 feet in $\frac{1}{12}$; and this, as has been said, is confirmed by the experiments taken at a medium. If now the barrel and position of the ball remaining the same, there be placed in the space that contained twelve penny-weight of powder three mentioned, only one penny-weight; it follows, that if the elasticity of the smaller charge be the same in proportion to its quantity with that of the larger, then the velocity of the bullet, when impelled by the explosion of the smaller charge, will be to the velocity of a bullet impelled by a greater charge in the subduplicate ratio of the quantities of the respective charges, that is, in the subduplicate ratio of 1 to 12. Consequently the velocity communicated by twelve penny-weight, being known to be that of 1670 feet in $\frac{1}{12}$, the velocity communicated by one penny-weight would be that of 482 feet in $\frac{1}{12}$ nearly; but by repeated trials, differing little from each other, it has been found, that the real velocity acquired by the ball in this case, from the explosion of one penny-weight of powder, was rather less than that of 400 feet in $\frac{1}{12}$. Whence it is evident, that the elasticity of one penny-weight of powder, when fired, is less in proportion to its quantity than that of twelve penny-weight, as it ought to be by the theory.

So if three penny-weight of powder be placed in the same manner with the one penny-weight last mentioned, the real velocity of the ball will acquire from the explosion will be from 740 to 750 feet in $\frac{1}{12}$. Whereas, supposing the elasticity of three penny-weight, when fired, to be in similar circumstances the same with that of twelve penny-weight, the velocity acquired by the ball should be 825 feet in $\frac{1}{12}$.

It is further to be observed, that the theory, established under the head GUN-POWDER, supposes, that in the firing of gunpowder about $\frac{1}{16}$ of its substance is converted by the sudden inflammation into a permanent elastic fluid, the elasticity of which, in proportion to its heat and density, is the same with that of the common air in the like circumstances; it farther supposes, that all the force exerted by gunpowder in its most violent operations, is no more than the action of the elasticity of the fluid thus generated; and these principles enable us to determine the velocities of bullets impelled from the arms of all kinds.

From this theory appears the inconclusiveness of what some authors have advanced relating to the advantages of particular forms for the *casts* or *balls* of mortars and cannons: for all their laboured speculations on this kind are evidently founded on very erroneous opinions about the actions of fired powder. Lib. cit. p. 92.

But it must not be dissembled, that however probable this theory may be from the experiments and reasons on which it is founded, there still remains a difficulty which seems not yet fully accounted for. The doubt arises from some experiments made before a committee of the Royal Society, who thereupon gave it as their opinion, that the change of the form in the chamber will produce a change of the distance to which the bullet is thrown. The experiments upon which this opinion was founded, were as follow:

Three brass chambers were made, whose depths were respectively three inches, 1½ inch and ½ inch; so turned as to fit the chamber of a brass mortar exactly; each of these chambers contained, when full, one ounce troy of powder. The ball was of brass, weighing nearly 350 ounces troy: the ball touched the powder of the charge in all these experiments. With the first chamber of three inches deep, the elevation of the mortar being 25°, the range taken at a medium of three shot was 741 feet; and the mean distance to which the ball was thrown with the chamber of ½ inch deep, was but 404 feet. As to the chamber of 1½ inch, it not fitting the chamber of the mortar exactly, the ranges were very irregular; but the least range, though fired late in the damp of the evening, exceeded the farthest range of the ½ inch chamber, and the farthest range extended to 586 feet; so that the committee seem well warranted in their opinion. The difficulty is to reconcile this with the foregoing theory. Its ingenious author has in general observed, in the account of his book given in the Phil. Trans. N° 469, p. 455, or Tracts, &c. vol. 1. p. 173, that when the charge is much smaller than the usual allotment of powder, there are some irregularities, as those arising from the different heat of small and large quantities of powder, to which head too perhaps must be referred the experiments made by the committee on the effect of different small chambers; but in customary charges, the velocities of bullets resulting from all the experiments hitherto made, are really such as the theory requires. And it appears, that these velocities are much greater than what they have been hitherto accounted for; and there are reasons from the theory to believe, that in cannon-shot the velocities may still exceed the foregoing computation. See Phil. Trans. N° 465, or Martyn's Abr. vol. viii. p. 253, &c.

If a bullet be laid at a considerable distance from the charge, the principles before laid down cannot then be applied to determine the velocity of the ball; they being only applicable in cases where the bullet is contiguous to the charge, or nearly so. For by what is shewn under the article GUNPOWDER, when the surface of fired powder is not confined by a heavy body, which it is obliged to impel before it, the flame dilates itself with a velocity much beyond what it can at any time communicate to a bullet by its continued pressure; because the powder having acquired a considerable degree of velocity of expansion, the first motion of the ball will not be produced by the continual pressure of the powder, but by the percussion of the flame. From whence it follows, that the velocity of a bullet, laid at a considerable distance before the charge, ought to be greater than what would be communicated to it by the pressure of the powder acting as before mentioned in this article. And this deduction from theory is confirmed from experience, by which it was found that a ball laid in a barrel, at the distance of 11½ inches from the breech, and impelled by twelve penny weight of powder, acquired in its discharge a velocity of about 1420 feet in 1'; whereas if it had been acted on by the pressure of the flame only, it would not have acquired a velocity of 1200 feet in 1'. The flame was found to hold true in all other greater distances (and also in lesser, though not in the same degree) and in all quantities of powder. And from hence arises a consideration of consequence in practice, which is, that no bullet should at any time be placed at any considerable distance before the charge, unless the piece be extremely well fortified; for a moderate charge of powder, when it has expanded itself through the vacant space, and reaches the ball, will, by the velocity each part has acquired, accumulate itself behind the ball, and be thereby prodigiously condensed; whence if the barrel be not extraordinarily strong, it must burst. This is confirmed by the experience of an exceeding good Tower musket of very tough iron, which being charged with twelve penny-weight of powder, and the ball being placed sixteen inches from the breech, upon firing the piece, part of the barrel, just behind the bullet, was swelled out to double its diameter, and two large pieces burst out of it. If the

powder be not placed together at the breech, but fastened uniformly through the whole cavity left behind the bullet, the progressive motion of the flame may hence be supposed to be prevented by the expansion of the neighbouring parts. And it was found that the ball being laid as before, 11½ inches from the breech, its velocity, in this case, instead of 1420 feet in 1', was only 1100 feet. See New Principles of Gunnery, part i. prop. 12, or Tracts, &c. p. 113, &c.

It appears from experience, that bullets of the same diameter and density impinging on the same solid substance with different velocities, will penetrate that substance to different depths, which will be in the duplicate ratio of those velocities nearly. Thus a leaden bullet of ½ of an inch in diameter, being fired against a solid block of elm with different velocities, as of 1700 feet, 730, and 450 feet in 1', the cavities were found to be 25, 55, 10, and 3, respectively; which are nearly in the duplicate proportion of those velocities: perfect regularity in case of this nature cannot be expected, when the unequal texture of the same piece of wood, and the change of the form of the bullet by the stroke, are considered.

From the penetration being in the duplicate proportion of the velocity of the impinging body, it follows, that the resistance of the wood, like that of gravity, is uniform. See New Principles of Gunnery, p. 94, 95, or Tracts, &c. p. 151. See GUN.

It appears from the account already given of Mr. Robins's admirable experiments, that the balls he made use of, in ascertaining their initial velocity, were very small, being only musket balls of about one ounce in weight; but other occupations, and his immature death, prevented his prosecuting his experiments with others of a larger size. This defect is now, in a very considerable degree, supplied by the experiments of Dr. Charles Hutton, in which he has made use of small cannon balls, from one pound to near three pounds weight, and formed a variety of conclusions, which may be applied to cannon-shot of the largest size. The machinery used by Dr. Hutton is much of the same kind with that of Mr. Robins; and the intention of his experiments is to discover the initial velocity of military projectiles, or the velocity with which a ball issues from a piece.

The gun, with which the experiments were made, was of brass; the diameter of the bore at the muzzle was 2.46 inches, and at the breech 2.08 inches; and the greatest cast iron ball, which it would admit, was 10½ ounces avoirdupois; but leaden balls weighing 1½ pounds, and long cylindrical shot weighing near three pounds, were sometimes used; the length of the bore was 42.6 inches, so that it was nearly 20½ calibres long. The powder was that commonly made for government, and the charge was 2, 4, or 8 ounces, put into a light flannel bag, and rammed without using any wax before it. The distance of the gun from the pendulum was 20 or 30 feet; and the depth of the penetration seemed to be near three inches in solid wood, when two ounces of powder were used.

The first course of experiments was performed in May 1775, the day being clear and dry; and it appears from the result, that the mean velocity of five shot, with two ounces of powder, was 526 feet in 1', and of two shot, with four ounces of powder, 915 feet in 1', which velocities are in the ratio of 1 to 1.45. But the mean weight of the balls in the former case was 17½ ounces, and in the latter 17½ ounces, and the ratio of the quantities of powder was that of 1 to 2. In this instance it is evident, the velocities are very nearly as the square roots of the quantities of powder directly, and the square roots of the weights of the balls inversely.

The second course of experiments was performed in June, in a clear and dry, but windy day. The mean velocity of the second and third shot, in these experiments, was 973 feet in 1', and of the fourth and fifth, 749 feet in 1', which numbers are in the ratio of 1.3 to 1; the charges were two ounces, and the balls were 19½ ounces and 46½ ounces respectively. In this instance, the velocity of the heavier shot is a little less than what would arise from the inverse ratio of the square roots of the weight of the shot. Some of these experiments were rendered doubtful by the effect of the wind; but as the mean velocity is 973, and only 526 in the former course, with the same charge of powder, though the balls were heavier with the greater velocity, in the proportion of 19 to 17 nearly, Dr. Hutton ascribes this remarkable difference chiefly to the windage in the first course, and takes occasion from hence to recommend the use of balls approaching in proportion nearer to the diameter of the bore of the gun than what is prescribed in the present establishment. The next course of experiments was performed on a clear, dry, and calm day, in the same month. In six shot on this occasion, the common mean weight of the ball was 18½ ounces; the mean velocity with two ounces of powder was 738 feet in 1', and that with four

ounces 1043 feet in 1" the ratio of which velocities is that of 1 to 1.414; or accurately the ratio of the square roots of the quantities of powder. The fourth course was performed with another machine on a fine clear day in July. The machinery for this and the following course, says Dr. Hutton, was to perfect, and every circumstance attending the experiments so carefully observed, that the conclusions resulting from them may be relied on with great safety. Those of the first day were made with leaden balls, and those of the other with iron ones, which differed greatly in weight; and as every other circumstance was the same, they afforded very good means for discovering the law of the different weights of shot, while the variations of the powder from 1 to 4 and 8 ounces, furnish us with the rule for the different quantities of it. The mean velocities with 1, 4, and 8 ounces of powder, were 873, 873, and 1162 feet in 1", which are in the ratio of 1, 1.414, and 1.49; and these numbers are nearly in the ratio of the square roots of the quantities of powder, viz. 1, 1.414, and 2. The mean weight of the balls used with 8 ounces of powder was 28½ ounces, and that with the 2 and 4 ounces 28½; the reciprocal subduplicate ratio of these is that of 1 to 1.006, in which proportion, increasing 1.9, the number for the greater velocity, and it becomes 1.91, which falls short of 2 by .09, or about the 14th part too small for the subduplicate ratio of the powder. This defect is ascribed to three causes, viz. the less length of cylinder through which the ball was impelled; the greater quantity of elastic fluid which escaped in this case than in the others by the windage, on account of the great velocity; and the greater quantity of powder blown out un-fired in this case than in that of the less velocities. Hence we may infer, how small the quantity of powder which is blown out un-fired in any of these cases, and the amazing quickness with which it fires in all cases; for although the time in which the ball passed through the barrel, when impelled by the eight ounces of powder, was not much different from the half only of the time in which it was impelled by the two ounces, it is evident that in half the time there was nearly four times the quantity of powder fired. In the last course of experiments, consisting of fifteen shot, the mean velocities with 2, 4, and 8 ounces of powder, were 701, 993, and 1397 feet in 1", which are as the square roots 1, 1.416, and 1.993, or nearly in the subduplicate ratio of the weights of powder, viz. 1, 1.414, and 2. The mean weight of the balls, which were iron, with the 2 and 4 ounces of powder, was 18½ ounces, and with the eight ounces of powder 18½ ounces; and, therefore, if the number 1.993 be diminished in the reciprocal subduplicate ratio of 18½ to 18½, it will become 1.955, which falls short of the number 2 by .045, or the 133d part of itself; and this defect is to be ascribed to the causes mentioned in the recited former course.

By comparing the corresponding velocities in these two last courses, viz. 6, 2 and 201, &c. it will be found that the ratio of the first or the velocities with two ounces of powder, is that of 1 to 1.4136; of the next two, viz. 873 and 993, that of 1 to 1.1375; and the ratio of the last, viz. 1162 and 1397, that of 1 to 1.2022. But the mean weight of the shot for the 2 and 4 ounces of powder, was 28½ ounces, and 28½ ounces; and for 8 ounces of powder, 28½ ounces, and 18½ ounces; the reciprocal subduplicate ratio of the former will be that of 1 to 1.214, and of the latter that of 1 to 1.241, which are little different from the real ratios above found. The conclusions that may be deduced from these experiments are the following, viz. that powder fires almost instantaneously, as Mr. Robins had before observed; that the velocities communicated to balls of the same weight, with different charges, are nearly in the subduplicate ratio of these charges; and to balls of different weights, with the same charge, nearly in the reciprocal subduplicate ratio of their weights; and, therefore, when the weights of balls and charges differ, the velocities are directly as the square roots of the charges, and reciprocally as the square roots of the weights, nearly; so that it would be a great improvement to make use of a shot of a long cord, or of heavier matter, as it would also be to diminish the windage; for thus one third or more of the quantity of powder might be saved; and by combining these two last improvements, half the quantity of powder might be saved; and a small gun might be made to produce the effect and execution of one two or three times its size, by discharging a shot of two or three times the weight of its natural ball or round shot. In this way a small ship might discharge shot as heavy as those of the greatest now made use of. Experiments of this kind performed with guns of various lengths, would likewise serve to determine the just length of cannon for shooting farthest with the same charge of powder. By means of such experiments, properly conducted and varied, we may be able to solve every question relating to military

projectiles, except such as depend on the resistance of the air to bodies moving swiftly in it. See a farther account of the machinery used by Dr. Hutton, and of his experiments, in the Phil. Trans. vol. lxxviii. for 1728. part i. art. 3. p. 50.

GUNPOWDER, a composition of salt-petre, sulphur, and charcoal, mixed together, and usually granulated, which easily takes fire, and, when fired, ratches, or expands, with great vehemence, by means of its elastic force. It is to this power we owe all the action and effect of guns, ordnance, &c. so that the modern military art, fortification, &c. depend wholly thereon.

The invention of gunpowder is ascribed, by Polydore Virgil, to a chemist, who, having accidentally put some of this composition in a mortar, and covered it with a stone, it happened to take fire, and blew up the stone.

Theret says, the person here spoken of was a monk of Frieburg, named Constantine Anselmi; but Bellefleur, and other authors, with more probability, hold it to be Bartholomew Schwartz, or the Black, who discovered it, as some say, about the year 1320; and the full use of it is ascribed to the Venetians, in the year 1380, during the war with the Genoese; and it is said to have been first employed in a place recently called Folla Chioda, now Chiochia, against Laurence de Medicis; and that all Italy made complaints against it, as a manifest contravention of fair warfare.

But what contradicts this account, and shows gunpowder to be of an older age, is, that Peter Masia, in his *Variations Reading*, mentions that the Moors being besieged in 1442, by Alphonsus XI. king of Castile, discharged a sort of iron mortars upon them, which made a noise like thunder; which is recorded by what Don Pedro, bishop of Leon, relates in his chronicle of king Alphonsus, who reduced Toledo, viz. that in a feud which between the king of Tunis, and the Moorish king of Seville, above four hundred and fifty years ago, those of Tunis had certain iron tubs or barrels, wherewith they threw thunder-bolts of fire.

De Cange adds, that there is mention made of gunpowder in the registers of the chambers of accounts in France as early as the year 1338.

Further, it appears that our Roger Bacon knew of gunpowder near a hundred years before Schwartz was born. That excellent friar tells us, in his treatise *De Secretis Operibus Artis & Naturae, & de Nullitate Magie*, cap. 6. which is by some supposed to have been published at Oxford in 1226, and which was undoubtedly written before his *Opus Majus*, in 1267, "that from salt-petre, and other ingredients, we are able to make a fire that shall burn at what distance we please." Dr. Plot, in his *History of Oxfordshire*, p. 236, &c. asserts us, that these "other ingredients" were explained, in a MS. copy of "the same treatise, in the hands of Dr. G. Longobin, as seen by Dr. Wallis, to be sulphur and wood coal." The writer of the life of Prior Bacon, in the *Biographia Britannica*, vol. i. says, that Bacon himself has divulged the secret of this composition in a cypher, by transposing the letters of the two words in chap. xi. of the above cited treatise; where it is thus expressed: *sed tamen salis petrae, lura mure can ubere* (i. e. *Carbunum pulvere*) *et sulphuris, et sic facit trinitatem & corpus christianum, hic fiat ars factum*; and from hence Bacon's biographer apprehends the words *carbunum pulvere* were transferred to the sixth chapter of Dr. Longobin's MS. In this same chapter Bacon expressly says, that sounds like thunder, and coruscations, may be formed in the air, much more horrible than those that happen naturally. He adds, that there are many ways of doing this, by which a city or an army might be destroyed; and he supposes that, by an artifice of this kind, Gideon defeated the Midianites with only three hundred men. Judges, chap. vii. There is also another passage to the same purpose, in the treatise *De Scientia Experimentalis*. See Dr. Jebb's edition of the *Opus Majus*, p. 474.

Mr. Robins apprehends (see the preface to his *Tracts*), that Bacon describes gunpowder not as a new composition, first proposed by himself, but as the application of an old one to military purposes, and that it was known long before his time. Marcus Grecus, an ancient author, who probably lived about the time of the Arabian physician Masia, in the beginning of the ninth century, and mentioned by him, in a treatise intitled *Libet Ignium*, of which Dr. Mead had a MS. copy, and cited by Dr. Jobin in the preface to *Bacon's Opus Majus*, describes two kinds of fire-works; one for flying, inclosed in a case or cartouch, made long and slender, and filled with the composition closely rammed like our modern rocket; and the other thick and short, strongly tied at both ends, and half filled, resembling our crackers; and the composition which he prescribes for both is two pounds of charcoal, one pound of sulphur, and six pounds of salt-petre, well powdered and mixed together in a stone mortar.

Mr. Dutens carries the antiquity of gunpowder much higher; and he refers to the accounts given by Virgil, *Æn.* lib. vi. ver. 585; Hyginus, *Fabul.* 61 & 650; Eustatius, ad *Odys.* x. 234. p. 1682. l. 2. Valerius Flaccus, lib. i. 662, and others, of Salomon's attempt to imitate thunder, presuming from hence that he used a composition of the nature of gunpowder. He adds, that Dion Cassius, in his *Hist. Rom.* in *Caigul.* p. 662, and Johannes Antiochensis, in *Chronica*, report the same thing of Caligula. The Brachmanns did the same, according to Theophrastus *Orat.* xxvii. p. 347. and also the Indians, whose practice is recorded by Philostratus, *Vita Apoll.* lib. ii. cap. 33. See likewise lib. iii. cap. 13. Dutens's inquiry into the Origin of the Discoveries attributed to the Moderns, p. 262, *see Eng.* vol. 1769.

See the preface to the Code of Genoa Laws, 1776; where it is asserted, that gunpowder was known to the inhabitants of Hindostan far beyond all periods of investigation.

GUNPOWDER, preparation of. There are divers compositions of gunpowder, with respect to the proportions of the three ingredients, to be met with in pyrotechnical treatises; but the process of making it up, is much the same in all.

For some time after the invention of artillery, gunpowder was of a much weaker composition than that now used by us, or that described by Marcus Grævus; which was chiefly owing to the weakness of their first pieces. See **CAN** and **CANNON**.

Of twenty-three different compositions, used at different times, and mentioned by Tartaglia in his *Quest.* & *Invent.* lib. iii. quest. 50. the first, which was the most ancient, contained equal parts of nitre, sulphur, and charcoal. When guns of modern structure were introduced, gunpowder of the same composition with the present came also into use. The cannon powder, in the time of Tartaglia, was made of four parts of salt petre, one of sulphur, and one of charcoal; and the musket powder of forty-eight parts of salt petre, seven parts of sulphur, and eight parts of charcoal; or of eighteen parts of salt petre, two parts of sulphur, and three parts of charcoal. The cannon powder was in meal, and the musket powder grained; and it is certain, that the invention of graining powder, which is a very considerable advantage, is a modern improvement. See the preface to Robins's *Math. Tracts*, p. 32, &c.

When the several ingredients of gunpowder are properly prepared, mixed, and grained, in the manner recited below; if the least spark be struck thereon from a steel and flint, the whole will be immediately inflamed, and burst out with extreme violence.

The effect is not hard to account for: the charcoal part of the grain, whereon the sparks fall, catching fire like tinder, the sulphur and nitre are readily melted, and the former also breaks into flame; and at the same time the contiguous grains undergo the same fate. Now it is known, that salt-petre, when ignited, rarefies to a prodigious degree.

See Isaac Newton reasons thus on the point: the charcoal and sulphur in gunpowder easily take fire, and kindle the nitre; and the spirit of the nitre, being thereby rarefied into vapour, rushes out with an explosion much after the manner that the vapour of water rushes out of an ebbles; the sulphur also, being volatile, is converted into vapour, and augments the explosion; and that the acid vapour of the sulphur, namely that which distils under a bell into oil of sulphur, entering violently into the fast body of the nitre, less looses the spirit of the nitre, and excites a greater fermentation, whereby the heat is further augmented, and the fast body of the nitre, is also rarefied into flame; and the explosion is thereby made more vehement and quick.

For if salt of tartar be mixed with gunpowder, and that mixture be warmed till it takes fire, the explosion will be greatly more violent and quick than that of gunpowder alone, which cannot proceed from any other cause than the action of the vapour of the gunpowder upon the salt of tartar, whereby that salt is rarefied. See *Philos. Trans.* MINANS.

The explosion of gunpowder arises, therefore, from the violent action whereby all the mixture being quickly and vehemently heated, is rarefied and converted into flame and vapour; which vapour, by the violence of that action, becoming so hot as to burst, appears in the form of a flame. See **DETONATION** of nitre.

M. de la Hire, in the History of the French Academy for 1702, ascribes all the force and effects of gunpowder to the spring or elasticity of the air included in the several grains thereof, and in the intervals or spaces between the grains: the powder being kindled, sets the springs of so many little parcels of air a-playing, and dilates them all at once, whence the effect; the powder itself only

serving to light a fire which may put the air in action; after which the whole is done by the air alone.

But it will appear from the experiments and observations of Mr. Robins, recited in the sequel of this article, that if this air be in its natural state at the time when the powder is fired, the greatest addition its elasticity could acquire from the flame of the explosion would not amount to five times its usual quantity, and, therefore, could not suffice for the two hundredth part of the effort, which is exerted by fired powder.

In order to understand the force of gunpowder, it must be considered, that whether it be fired in a vacuum or in air, it produces by its explosion a permanent elastic fluid. For if a red-hot iron be included in a receiver, and the receiver be exhausted, and the gunpowder be then let fall on the iron, the powder will take fire, and the mercurial gage will suddenly descend upon the explosion; and though it immediately ascends again, yet it will never rise to the height it first stood at, but will continue depressed by a space proportioned to the quantity of gunpowder which was let fall on the iron. By this means (firing small quantities at a time) the mercurial gage may be reduced from 24 inches to 22. Now this experiment, which has been often repeated, proves the proposition with respect to the production of a permanent elastic fluid in a vacuum; for the descent of the gage could only be effected by the pressure of some new generated fluid in the receiver, balancing in part the pressure of the external air. That this fluid, or some part of it at least was permanent, appears from hence, that though in these experiments the quicksilver ascended after the operation, yet next day it had ascended no higher than 22½, at which place it seemed to continue fixed. And that this fluid is elastic, is proved from the descent of the mercurial gage; since the quantity of matter contained in this fluid could not by its gravity alone have sunk the quicksilver by the least sensible quantity; also from its extending itself through any space, however great, the experiment succeeding in either a large or small receiver, only the larger the receiver the less will be the descent of the mercurial gage to the same quantity of powder: the pressure of the generated fluid diminishing as its density diminishes. See *Phil. Trans.* N° 295.

The same production likewise takes place, when gunpowder is fired in the air; for if a small quantity of powder be placed in the upper part of a glass tube, and the lower part of the tube be immersed in water, and the water be made to rise so near the top, that only a small portion of air is left in that part where the gunpowder is placed; if in this situation the communication of the upper part of the tube with the external air be closed, and the gunpowder be fired (which may easily be done by a burning-plaf) the water will, in this experiment, descend on the explosion, as the quicksilver did in the last, and will always continue depressed below the place at which it stood before the explosion; and the quantity of this depression will be greater, if the quantity of powder be increased, or the diameter of the tube be diminished. From whence it is proved, that as well in air as in a vacuum, the explosion of fired powder produces a permanent elastic fluid. Hauksbee, *Phys. Mechan. Exp.* p. 11. This release of real and elastic air from various fulminants, in certain circumstances, is now a well known and incontestable fact. See **AIR**.

It also appears from experiment, that the elasticity or pressure of the fluid produced by the firing of gunpowder, in *cævis paribus*, directly as its density. This follows from hence, that, if in the same receiver a double quantity of powder be let fall, the mercury will subside twice as much as in the firing of a single quantity. For the vapour produced from the double quantity, being contained in the same receiver, will be of double the density of that produced from the single quantity; whence the elasticity or pressure, estimated by the descent of the mercury, being likewise double, the pressure is directly as its density. Also the descents of the mercury, when equal quantities of powder are fired in different receivers, are reciprocally as the capacities of those receivers; and consequently as the density of the produced fluid in each.

To determine the elasticity and quantity of this elastic fluid, produced from the explosion of a given quantity of gunpowder, Mr. Robins premises, that the elasticity of this fluid increases by heat, and diminishes by cold, in the same manner as that of the air; and that the density of this fluid, and consequently its weight, is the same with the weight of an equal bulk of air, having the same elasticity and the same temperature. From these principles, and from the experiments by which they are established, for a detail of which we must refer to the book itself, so often cited in these articles, he concludes, that the fluid produced by the firing of gunpowder will be nearly 2½ of the weight of the generating gunpowder; and

and the ratio of the respective bulks of the powder, and the fluid produced from it, will be, in round numbers, 1 to 244.

Count Salazar, in his *Miscell. Phil. Math.* Soc. priv. Taurin. p. 125, makes the proportion as 1 to 222, which, he says, agrees with the computation of Mess. Hauksbee, Amontons, and Beldor.

Hence we are certain, that any quantity of powder fired in any confined space, which it adequately fills, exerts at the instant of its explosion against the sides of the vessel containing it, and the bodies it impels before it, a force at least 244 times greater than the elasticity of common air, or, which is the same thing, than the pressure of the atmosphere; and this without considering the great addition which this force will receive from the violent degree of heat with which it is endowed at that time; the quantity of which augmentation is the next head of Mr. Robins's enquiry. He determines that the elasticity of the air is augmented, when heated to the extreme heat of red-hot iron, in the proportion of 756 to 1064 nearly; and supposing that the flame of fired gunpowder is not less hot than red-hot iron, and the elasticity of the air, and consequently of the fluid generated by the explosion, being augmented by the extremity of this heat in the ratio of 1064 to 756, it follows, that if 244 be augmented in this ratio, the resulting number, which is 999, will determine how many times the elasticity of the flame of fired powder exceeds the elasticity of common air, supposing it to be confined in the same space which the powder filled before it was fired.

Hence then the absolute quantity of the pressure exerted by 25-powder at the moment of its explosion, may be assigned; for since the fluid then generated has an elasticity 999, or in round numbers, 1000 times greater than common air; and since common air, by its elasticity, exerts a pressure on any given surface equal to the weight of the incumbent atmosphere, with which it is in equilibrium, the pressure exerted by fired powder, before it has dilated itself, is 1000 times greater than the pressure of the atmosphere, and consequently the quantity of this force on a surface of an inch square, amounts to above six ton weight; which force, however, diminishes, as the fluid dilates itself.

Dr. Ingenhousz accounts for the effect of gunpowder by observing, that nitre yields by heat a surprising quantity of pure dephlogisticated air, and charcoal a considerable quantity of inflammable air; the fire employed to inflame the powder extricates these two airs, and sets fire to them at the instant of their extrication. See his theory largely explained in *Phil. Trans.* vol. lxxix. part ii. art. 26.

Though it has here been supposed, that the heat of gunpowder, when fired in any considerable quantity, is the same with iron heated to the extremity of a red heat, or to the beginning of a white heat, yet it cannot be doubted but that the fire produced in the explosion is somewhat varied (like all other fires) by a greater or less quantity of fuel; and it may be presumed, that according to the quantity of powder fired together, the flame may have all the different degrees from that of a languid red heat to the heat sufficient for the vitrification of metals; but as the quantity of powder requisite for the production of this last mentioned heat is certainly greater than what is ever fired together for any military purpose, we shall not be far from our scope, if we suppose the heat of such quantities as come more frequently in use to be, when fired, nearly the same with the strongest heat of red-hot iron; allowing a gradual augmentation to this heat in larger quantities, and diminishing it when the quantities are very small. *Prin. of Gunnery*, in Robins's *Math. Trans.* vol. i. p. 59, &c.

We may observe, that the variations of the density of the atmosphere do not any way alter the action of powder. By comparing several trials made at noon in the hot summer sun, with those made in the freshness of the morning and the evening, no certain difference could be perceived; and it was the same with those made in the night and in winter. Indeed, considering that the same quantity of that elastic fluid in which the force of powder consists, is generated in a vacuum and in common air, it is difficult to conceive how this force can be affected by the greater or less density of the atmosphere.

But the moisture of the air has a very great influence on the force of powder; for that quantity which, in a dry season would communicate to a bullet a velocity of 1200 feet in one second, will not in damp weather communicate a velocity of more than 12 or 1300 feet in a second, or even less, if the powder be bad and negligently kept. Robins's *Math. Trans.* vol. i. p. 101, &c.

This agrees with an experiment made before a committee of the Royal Society, where powder having been dried by being put into a phial placed in boiling water, threw a ball out of a mortar twice as far as the same quantity of powder taken out of the same barrel before it was dried.

Now the ranges under the same circumstances of charge, elevation, &c. being as the squares of the velocities of the ball, these velocities, in this experiment, will be to each other nearly as 17 to 12, which give ranges as 289 to 144. *Phil. Trans.* N^o 465. p. 182, 183.

If powder be damp, that made with equal quantities of it out of the same parcel, will differ considerably from each other, perhaps ten times more than if the powder was in good order. A small charge seems to lose a greater part of its force than a larger, each being equally damp. Another circumstance attending damp powder is, a remarkable foulness in the piece, after firing, much beyond what arises from an equal quantity of dry powder.

That powder will imbibe moisture from the air, and thereby increase in weight, is certain. A parcel of very good powder, being placed on a white paper, pierced with a great number of fine holes, and held over the steam of hot water, the powder in half a minute was increased about $\frac{1}{2}$ in weight. Another parcel continuing longer in the steam was increased by $\frac{1}{3}$ part. That the moisture of the atmosphere has a like effect, appears from this, that an ounce of powder kept for some time in a room having a fire in it every day, being dried before the fire, lost above $\frac{1}{10}$ part of its weight; one third of which it regained in less than two hours, by being removed to a part of the room distant from the fire. And as the air is often much moister than when this experiment was tried, and the open air is more moist than a room with a fire, it cannot be doubted but that the twentieth or thirtieth part of the substance of the best powder is water. Now as a certain quantity of water mixed with powder will prevent its firing at all, it cannot be doubted but every degree of moisture must abate the violence of the explosion; and hence the effects of damp powder are not hard to account for.

It is to be observed, that the moisture imbibed by powder does not render it less active when dried again. Indeed, if powder be exposed to the greatest damps without any caution, or if common salt abounds in it, as often happens through negligence in refining the nitre, the moisture it imbibes may, in such cases, be perhaps sufficient to dissolve some part of the nitre, which is a lasting damage that no drying can retrieve. But when tolerable care is taken in preserving powder, and the nitre it is composed of has been well purged from common salt, it will retain its force much longer than is usually supposed; and it is said that powder has been known to have been preserved for fifty years, without any apparent damage from its age.

Some care is necessary in the drying of damp gunpowder; for there is a degree of heat, which though not sufficient to fire the powder, will yet melt the brimstone, and destroy the texture of the grains. Nay more, there is a heat with which the brimstone will flame and burn away gradually, and yet the powder will not explode; if of this any one may satisfy himself by heating a piece of iron red-hot, and then throwing a few grains of powder on it at different intervals, during the time of its cooling; for by this means he will find, that at a certain time the separate grains that fall on the iron will not explode, but will burn with a small blue flame for some space of time, the grain still remaining unconsumed. Indeed, when it has begun to do in this manner, it sometimes ends with exploding; but this more commonly happens when a number of grains lie near together; for then, though each separate flame is not sufficient to explode its respective grain, yet the whole fire made by them altogether, grows strong enough at last to end in a general explosion; however, by attending to the proper temperature of the iron, and spreading the grain, two or three inches square may be covered with a blue lambent flame, which will last a considerable time without any explosion, and the grains afterwards will not apparently have lost either their colour or their shape. Now since these grains, when the brimstone is thus burnt or even melted out of them, will no longer act as powder, it is evident that powder may be spoiled by being dried with too violent a heat. Robins, vol. i. p. 104, &c.

The velocity of expansion of the flame of gunpowder, when fired in a piece of artillery, without either bullet or other body before it, is prodigious. By the experiments of the author so often quoted, it grows this velocity cannot be much less than 7000 feet in a second. This however must be understood of the most active part of the flame. For, as was observed before, the elastic fluid, in which the activity of gunpowder consists, is only $\frac{1}{2}$ of the substance of the powder, the remaining $\frac{1}{2}$ will be the substance to be mixed with the elastic part, and will by its weight retard the activity of the explosion; and yet they will be so completely united as to move with one common motion; but the unelastic part will be less accelerated than the rest, and some of it will not be carried out of the barrel, as appears by the considerable quantity

of viscous matter, which adheres to the inside of all fire-arms after they have been used. These inequalities in the expansive motion of the flame, render it impracticable to determine its velocity otherwise than from experiments. The foundation of which determination is, that a barrel being fixed in a proper situation on a pendulum, such as is described under the head *GUNNERY*, and being charged with twelve penny-weight of powder, without either ball or wad, the powder being only put together by the rammer; on the discharge the pendulum ascended through an arch whose chord was 10 or 10½ inches.

Now if the piece be again loaded with the same quantity of powder, rammed down by a wad of tow weighing one penny-weight, it may be supposed that this wad, being very light, will precisely acquire that velocity, with which the elastic part of the fluid will expand itself when uncompressed; and it was accordingly found, that the chord of the ascending arch was by this means augmented to twelve inches; so that by the additional weight of one penny-weight of matter moving with the velocity of the swift part of the vapour, the pendulum ascended through an arch whose chord was two inches longer than before. And by calculating upon these facts, and the principles laid down in his book, Mr. Robins determines that the velocity with which this one penny-weight of matter moved, must be about 7000 feet in one second.

It is this prodigious celerity of expansion of the flame of fired gunpowder, which is its peculiar excellence, and the circumstance in which it so eminently surpasses all other inventions, either ancient or modern, for the purpose of military projections: for as to the quantity of motion of these projectiles only, many of the warlike machines of the ancients required this in a degree far surpassing that of our heaviest cannon-shot or shells; but the great celerity given to these bodies cannot be in the least approached by any other means than by the flame of powder. The reason of this difference is, that the ancients could by weights, or the elasticity of springs and stretched chords, augment their powers to any degree desired; but then each addition of power brought with it a proportional addition of matter to be moved; so that as the power increased, those parts of the machine which were to communicate motion to the projectile, and were consequently to move with it, were likewise increased; and thence it necessarily happened, that the action of the power was not solely employed in giving motion to the impelled body, but much the greatest part of it was spent in accelerating those parts of the machine in which the power resided, to enable them to pursue the body to be projected with perpetual impulse, during its whole passage through the extent of their activity. Hence then it came to pass, that, though these ancient machines could throw enormous weights, they could project them but with small degrees of celerity, compared with what we can communicate to our cannon and musket-balls; whence, in all operations where these great velocities are useful, our machines are infinitely superior to those of antiquity; although, in more confined and shorter projections, these last have some advantage which may yet render them worthy of the attention of those military geniuses, who have capacity enough to consider each part of the profession according to its true and genuine value, independent of the partial estimation of the times they live in. Ibid. p. 112.

Gunpowder is a commodity of such consequence, both in respect of speculation, of war, and of commerce (the consumption thereof being incredible), that it will deserve a more particular detail. To make *gunpowder* duly, then, regard is to be had, that the salt-petre be pure, and in fine large crystals or shavings; otherwise, it is to be purified, by taking away its fat or common salt, and earthy part, thus: dissolve ten pounds of nitre in a sufficient quantity of fair water; settle, filtrate, and evaporate it in a glazed vessel, to the diminution of half, or till a pellicle appear on it; the vessel may then be taken off from the fire, and set in a cellar: in twenty-four hours the crystals will flower, which separate from the liquor; and after the like manner may the liquor be crystallized several times, till all the salt be drawn forth: this done, put it into a kettle, and that on a furnace with a moderate fire, which gradually increase till it begins to smoke, evaporate, lose its humidity, and grow very white: it must be kept continually stirring with a ladle, for fear it should return to its former figure, whereby its goodness will be taken away; after that, so much water is to be poured into the kettle as will cover the nitre; and when it is dissolved, and reduced to the consistency of a thick liquor, it must be stirred with a ladle, without intermission, till all the moisture is again evaporated, and it be reduced to a dry and white meal. See *SALT-PETRE*, and *NITRUM PURIFICATUM*.

The like regard is to be had to the sulphur, choosing that

VOL. II. N^o 161.

which is in large lumps, clear and perfectly yellow; not very hard, nor compact, but porous; nor yet too much flinty; and if, when set on fire, it freely burns away all, leaving little or no residuum matter, it is a sign of its goodness; so likewise, if it be pressed between two iron plates that are hot enough to make it run, and in the running appear yellow, and that which remains of a reddish colour, it may be concluded to be fit for the purpose. But in case the same be foul and impure, it may be purified in this manner: melt the sulphur in a large iron ladle, or pot, over a very gentle coal fire, well kindled, but not flaming; then pour off all that rises on the top, and swims upon the sulphur; take it presently after from the fire, and drain it through a double linen cloth, letting it pass at leisure; so will it be pure, the gross filthy matter remaining behind in the cloth. See *SULPHUR*.

Some persons, misled by an experiment of Dr. Hales, which shews that burning sulphur does not generate elastic air, but diminishes the quantity of common air, have imagined that the sulphur was an unnecessary and even injurious ingredient of *gunpowder*. But M. Berneux has found by experiments, that the force of *gunpowder* was nearly doubled by addition of the sulphur. The use of sulphur, says the translator of the Chemical Dictionary, seems to be not to increase the explosion immediately by its own combustion, but to accelerate the combustion of the other ingredients, in consequence of its being more easily inflammable than the charcoal.

For the charcoal, the third ingredient, such should be chosen as is large, clear, and free from knots, well burnt and cleaving. See *CHARCOAL*.

The charcoal of light woods has been generally employed; but M. Berneux affirms from experience, that the charcoals of heavy and hard woods, if they have been well made, are as fit for the purpose. The charcoal not only concurs with the sulphur in supplying the inflammable matter, which causes the *DETONATION* of the mine, but also considerably adds to the explosive power of the detonating nitre, by the quantity of elastic vapour expelled during its combustion.

Powder being a mixture of sulphur and charcoal, which are very inflammable substances, with salt-petre, which in itself is not, if the salt-petre be too much in quantity, when compared with the other two, their burning may not be sufficient to consume the whole of the salt-petre; whence the fire may be less violent, and consequently the powder less vigorous, than if some of the salt-petre was taken away, and a like quantity of the other materials were added in its stead. On the other hand, if the salt-petre in the composition be less than what the burning of the other two substances can easily consume, the fire will be less active than it ought to be, because it is not augmented to much as it would be if a larger quantity of salt-petre had been added to the composition.

Hence it appears that the goodness of powder is not to be estimated only from the quantity of salt-petre contained in it, although that substance seems to be the basis of the elastic fluid, in which its force consists: for since the converting of the salt-petre into that fluid, and the elasticity of the fluid, afterwards, depend in some measure on the violence of the fire produced at the explosion, it is plain that there is a certain proportion in the mixture of the materials, which will best contribute to this purpose, and consequently to the perfection of the powder.

What this proportion is, has been ascertained by experience; and it seems now to be generally agreed, that in any quantity of powder three-fourths of it should be salt-petre, the remaining one-fourth consisting of equal quantities of sulphur and charcoal. This is the proportion followed by the French, and by most nations in Europe; we, indeed, pretend to a greater degree of nicety in our proportions; though, if it is said, they do not greatly differ from what is here mentioned, nor is it certain that they are preferable: this, however, may be depended on, that no methods of proving powder, hitherto generally practised in England, could at all ascertain the difference; and other powders made with the usual proportions, are nothing inferior to ours.

But it is not the due proportion of the materials only, which is necessary to the making of good powder; another circumstance, not less essential, is the mixing them well together; if this be not effectually done, some parts of the composition will have too much salt-petre in them, and others too little; and in either case there will be a loss of strength in the powder. Robins, ubi supra, p. 119, &c.

There have been commonly enumerated three kinds of powder, viz. *cannon-powder*, *musket-powder*, and *pistol-powder*; of each of these again there are two sorts, a *stronger*, and a *weaker*; all which differences arise only from the various proportions.

The proportions are thus: in the strongest *cannon-powder*,

10 K 10

to every hundred pounds of salt-petre, twenty-five pounds of sulphur are generally allowed, with the same quantity of charcoal; and in the weaker *common-powder*, to every hundred pounds of salt-petre, twenty pounds of sulphur, and twenty-four pounds of charcoal. As for the stronger *military-powder*, a hundred pounds of salt-petre require eighteen pounds of sulphur, and twenty of charcoal; and in the weaker there go to a hundred pounds of salt-petre, fifteen of sulphur, and eighteen of charcoal. In the stronger *pile-powder*, a hundred pounds of salt-petre require twelve of sulphur, and fifteen of charcoal; whereas the weaker has to a hundred pounds of salt-petre, only ten of sulphur, but eighteen of charcoal.

Other authors prefer the different proportions: Senleowitz, for mortars, directs a hundred pounds of salt-petre, twenty-five of sulphur, and as much of charcoal; for great guns, a hundred pounds of salt-petre, fifteen of sulphur, and eighteen of charcoal; for muskets and pistols, a hundred pounds of salt-petre, eight of sulphur, and ten of charcoal. The author of the Dictionary of Chemistry, recommends seventy-five parts of purified nitre, fifteen and a half parts of charcoal, and nine and a half parts of sulphur.

Micliarus extols the proportion of one pound of salt-petre to three ounces of charcoal; or two, or two and a quarter of sulphur: than which, he asserts, no *gunpowder* can possibly be stronger.

He adds, that the usual practice of making the *gunpowder* weaker for mortars than guns, as in the example above, is without any foundation, and renders the expense needlessly much greater: for whereas to load a large mortar twenty-four pounds of common is required, and consequently to load it ten times, two hundred and forty pounds; he shows by calculation, that the same effect would be had by one hundred and eighty pounds of the strong powder.

GROUNDING, or the practice of making the all the ingredients are first to be finely powdered, then moistened with file water, or vinegar, or spirit of wine, or water and spirit of wine mixed together, or urine; afterwards all must be well beat for the space of twenty-four hours at least, and then granulated after the following manner: a sieve is to be prepared with a bottom of thick parchment made full of round holes, and the former beaten mals moistened before-hand with twenty ounces of spirit of wine, twelve of spirit of wine-vinegar, thirteen of spirit of wine, two of spirit of sal ammoniac, and one ounce of camphire dissolved in spirit of wine; and let all these be mingled together; otherwise, take forty ounces of brandy, and one of camphire, and let them be mixed and dissolved for the same purpose: when the whole compound is made up into balls as big as eggs, put them into the sieve, and with them a wooden ball, which move up and down about the sieve, so that it may break the balls of powder, and make it pass through the little holes in corns.

For greater quantities, **MILLS** are usually provided, by means of which, more work may be performed in one day, than a man can do in a hundred.

Gunpowder may also be made of several colours; but the black is the most serviceable of any.

To make white powder proceed thus.—Take ten pounds of salt-petre, one of sulphur, and two of the saw-dust of elder, or the like wood, powdered very fine; mix them together, and use the former method. (Or thus: with ten pounds of nitre, and a pound and a half of sulphur dried, and finely powdered, mix two pounds of saw-dust, &c. or, instead of that, rotten wood dried and powdered, with two pounds and three ounces of salt of tartar; whereas make powder to be kept close from the air.

It is also to be noted, that in making *pile-powder*, if you would have it stronger, it should be flured up several times while in the mortar, and moistened with water dissolved in vinegar, or lemon juice, or some other very vegetable substance in an alembic, and then beaten for twenty hours, as aforesaid.

Caru-powder is of so much greater force than white in dust or meal, that it is generally concluded the larger grains are stronger than the smaller: for which reason, *caru-powder* is granulated larger than other powders; and therefore *gun* in loading should not be beat home into the piece, so as to bruise the grains. Powder is smoothed for small arms by the following operation: a hollow cylinder or calk is mounted on an axis, turned by a wheel; this calk is half filled with powder, and turned for six hours, and thus by the mutual friction of the grains of powder it is smoothed. The fine mealy parts thus separated or worn off from the rest is again granulated. There are several ways to prove the goodness of *gunpowder*: 1. By light; for if it be too black, it is too moist, or has too much charcoal in it; so also if rubbed upon white paper, it blackens it more than good powder does: but if it be of a kind of azure colour, some-

what inclining to red, it is a sign of good powder. 2. By touching; for if in crushing it with your fingers ends, the grains break easily, and turn into dust, without feeling hard, it has too much coal in it; or if in pressing under your fingers upon a smooth hard board, some grains feel harder than the rest, or, as it were, dent your fingers ends, the sulphur is not well mixed with the nitre, and the powder is taught. 3. By burning, wherein little heaps of powder are laid on white paper three inches or more asunder, and one of them fired; which, if it only fires all away, and that suddenly, and almost imperceptibly, without firing the rest, and makes a small thundering noise, and a white smoke arises in the air almost like a circle, the powder is good; if it leaves black marks, it has too much coal, or is not well burnt: if it leaves a greenish, the sulphur or nitre are not well cleaned or ordered. Again, if two or three corns be laid on paper an inch distant, and fire be put to one of them, and they all fire at once, leaving no sign behind, but a white smoky colour in the place, and the paper not touched, the powder is good. So also if fired in a man's hand, and it burns not, but if black knots appear, which burn downwards in the place where proof was made, after firing, it is not strong enough, but wants nitre. The method most commonly followed for this purpose, here with us, says Mr. Robins, is to fire a small heap of it on a clean board, and to attend nicely to the flame and smoke it produces, as likewise to the marks it leaves behind on the table; from all which instructive particulars the merit of the powder is ascertained with great accuracy, as is pretended: but besides this uncertain method, which how much sooner it may be practiced, none will undertake seriously to defend, there are, on particular occasions, other contrivances made use of, all which bear some analogy to the common powder-triers, sold at the shops; only they are more artfully fabricated, and instead of a firing they move a weight, which is a more certain and equal power.

The method of proving *gunpowder*, as practised by our board of ordnance, is to take out of several barrels a measure, of about the size of a rhimble, which is forced upon a sheet of fine writing-paper, and then fired; if the inflammation is very rapid, the smoke rises perpendicularly, and the paper is neither burnt nor spotted, the powder is judged to be good: then two drams of the same powder, being exactly weighed, are put into a machine, called *epicote* or *gunpowder* prover, which if it raises a weight of 24lb. to the height of 31 inches, it is received into the king's magazines; and is hence called *ordnance* or *government-powder*.

But these machines, says Mr. Robins, though more perfect than the common powder-triers, are yet liable to great irregularities; for as they are all moved by the instantaneous stroke of the flame, and not by its continued pressure, they do not determine the force of the fired powder with that certainty and uniformity which were to be desired in these kinds of trials: and therefore, the method followed by the French, in the receiving of powders from the makers, seems to be much better. Their practice is thus:

They have, in each magazine, a small mortar cast with its bed, according to a determined pattern, which is the same throughout the kingdom: this mortar is always pointed at 45°, and it contains just three ounces of powder; and it is a standing maxim, that no powder can be received into their store, unless three ounces of it, placed in the chamber of this mortar, throw a solid ball of 11 inches diameter to the distance of at least 55 French fathoms. But if each barrel of powder was to be proved in this manner, the trouble of changing the mortar, &c. would be intolerable, and the delay so great, that no business of this kind could ever be finished. The method by firing against a pendulum, in the manner mentioned under the head GUNNERY, seems a ready way; but still it requires some nicety and time, which it were to be wished could be obviated. Robins's Mathematic. Tracts, vol. i. p. 121.

To recover damaged powder, the method of the powder merchants is this; they put part of the powder on a fall-cloth, to which they add an equal weight of what is really good; and with a shovel mingle it well together, dry it in the sun, and barrel it up, keeping it in a dry and proper place.

Others again, if it be very bad, restore it by moistening it with vinegar, water, urine, or brandy; then they beat it fine, scarce it, and to every pound of powder add an ounce, an ounce and an half, or two ounces (according as it is decayed), of melted salt-petre; and afterwards these ingredients are to be moistened and mixed well, so that nothing may be discerned in the composition; which may be known by cutting the mals, and then they granulate it as aforesaid.

In case the powder be in a manner quite spoiled, the only way

way is to extract the salt-petre with water, according to the usual manner, by boiling, filtering, evaporating, and crystallizing; and then, with fresh sulphur and charcoal, to make it up anew again.

Persons keeping more than 200 lb. weight of gunpowder at one time, within the cities of London and Westminster, or their suburbs, &c. are liable to forfeitures if it be not removed, and, judges of the peace may issue warrants to search for, seize, and remove the same, 5 and 11 Geo. I. and 5 Geo. II. cap. 20. All the acts relating to the making, keeping, and carrying of gunpowder are reduced into one, by 12 Geo. III. cap. 61.

GUN-SHOT wounds. See WOUND.

GUNTER'S LINE, called also *line of lines*, and *line of numbers*, is a graduated line usually placed on scales, rulers, sectors, &c.

This line consists of the logarithms transferred upon a ruler, from the tables, by means of a scale of equal parts, so as to answer much the same purposes, instrumentally, as the logarithms themselves do arithmetically. What the logarithms do by addition and subtraction, is done in this line by turning a pair of compasses this way and that.

This line has been contrived various ways, for the advantage of having it as long as possible. As, first, on the two-foot ruler, contrived by Edmund Gunter, and called *Gunter's scale*; whence also the line itself took its popular denomination *Gunter's line*.

After this, Wingate doubled the line, or laid it together, so as one might either work right on, or across. Then it was projected in a circle, by Oughtred, and made to slide by the same author; and lastly, it was projected in a kind of spiral, by Brown.

The method of using or applying, is much the same in all; except that in Gunter's and Wingate's way, common compasses are used; in Oughtred's and Brown's flat compasses, or an opening index; and in sliding rules, no compasses at all.

Description of GUNTER'S line. The whole length of this line is divided into two equal intervals, usually called *radii*; the first begins at the left-hand with the number 1; the middle point between the two radii, where the first ends and the second begins, is also marked with number 1; and the end of the second radius, which terminates the line at the right-hand end, is marked with the number 10, against which are inscribed the letters *mm*. Each of these equal radii or intervals is divided into 9 equal spaces, marked 2, 3, 4, 5, 6, 7, 8, 9; but the spaces in one radius are exactly of the same lengths as the spaces alike marked in the other radius, each of these 9 unequal spaces are subdivided, first into ten unequal, and then each of these into two or more parts, such as those spaces can conveniently contain. If the left-hand 1 stands for the number one, the middle 1 represents the number 10, and the 10 at the right-hand end stands for the number 100, then the figures 2, 3, 4, &c. in the first radius stand for the numbers 2, 3, 4, 5, 6, 7, 8, 9; and the like figures in the second radius stand for the numbers 20, 30, 40, 50, 60, 70, 80, and 90; and the ten first subdivisions in the spaces of the second radius stand for the respective units between the marked spaces. If the left-hand 1 be called 10; the middle 1 stands for 100, and the 10 at the right-hand stands for 1000; the several spaces and subdivisions in the first interval are then to be estimated as those were estimated in the second radius, when the right-hand end stood for 100; but now, in the second interval, the first subdivisions in the spaces stand for hundreds, and the lesser divisions of these stand for such parts of 100, as there are parts introduced; thus, where only 2 of the last subdivisions can be introduced, each stands for 50; where 4 can be contained, each stands for 25; if 5 are put in, each stands for 20; and where 10 are introduced, each stands for 10; again, if the first 1 be called 100, the second 1 stands for 1000; and the 10 at the end stands for 10000, &c. if the first 1 stands for $\frac{1}{10}$, the second 1 stands for 1, and the 10 at the end stands for 10; and in this case, the numbered divisions in the second radius stand for the units between 1 and 10; the first subdivisions stand for tenth-parts of unity, and the second subdivisions stand for the parts of tenths, according to the number of these second subdivisions, &c. so that whatever values are put upon any division or subdivision in the second radius, the value of the corresponding division in the first radius will be only a tenth part, and vice versa; thus, if the division marked 5 in the second radius stands for 5000, or 500, or 50, or 5, &c. then the 5 in the first radius will stand for 500, or 50, or 5, or $\frac{5}{10}$, or $\frac{5}{100}$, &c.

Construction of GUNTER'S line. From a scale of equal parts, accurately divided, and of such a length, that 20 of the primary divisions shall make the whole length of the intended scale of numbers, take the first 10 of these divisions, and lay this distance down twice on the logarithmic scale, making 2 equal intervals; marking the first

point 1, the second 1 (or rather 10), and the third 10 (or rather 100). From the same scale take the distances expressed by the 3rd figures of the logarithms of the numbers 2, 3, 4, 5, 6, 7, 8, 9 respectively, rejecting the indices, viz. 301, 477, 622, 699, 778, 845, 903, 954; lay these distances on each interval of the logarithmic scale, between the marks 1 and 10, 10 and 100, reckoning each distance from the beginning of its interval, viz. from 1 and from 10; and mark these distances with the figures 2, 3, 4, 5, 6, 7, 8, 9, in order. The distances expressing the logarithms of the numbers between 10 and 20, 20 and 30, 30 and 40, 40 and 50, 50 and 60, 60 and 70, 70 and 80, 80 and 90, 90 and 100, rejecting the indices, are also to be taken from the scale of equal parts, and laid on the logarithmic scale, in each of the primary intervals between the marks 1 and 2, 2 and 3, 3 and 4, 4 and 5, 5 and 6, 6 and 7, 7 and 8, 8 and 9, 9 and 10, respectively, reckoning each distance from the beginning of its respective primary interval. The last subdivisions of the second primary interval are to be divided into others, as many as the scale will admit of, by laying down the logarithms of such intermediate divisions.

The accuracy of the division of this line may be determined by taking with a pair of compasses the distance between the divisions marked with the numbers 1 and 2, which will reach from 2 to 4, from 4 to 8, from 8 to 16, &c. and from 1 to 3, from 3 to 6, from 6 to 12, &c. and also from 1 to 2.5, from 2.5 to 5, from 5 to 10, &c. or the same distance applied to any one of the divisions between 1 and 2, will reach from thence to divisions found always by doubling the last number. The same work may be done without compasses, by moving the slider till the left-hand 1 on the line of numbers stands against the division expressing any number counted on the fixed line of numbers, then will the divisions 2, 4, 8, 16, 32, &c. on the slider stand against the respective divisions on the fixed line, which will represent twice, 4 times, 8 times, 16 times, &c. the division against which the 1 on the slider was set. Their divisions on the fixed line which correspond to the divisions 2, 4, 8, 16, &c. on the slider will be cut by the edge of the brass index by moving it along to the divisions on the slider.

To find a division or point in the line of numbers answering to any given number. Let the number be 654; seek in the second radius between the figures 6 and 7 for the fifth of the first subdivisions, between this fifth and sixth are 4 second subdivisions, each of which answers to 2.5 units; then will a point taken a little nearer to the second than the first of these smaller subdivisions answer to the number 654 very nearly; the corresponding point in the first radius answers to the number 65.4, and if this point in the first radius answered to 654, the like point in the second would answer to 6540. Let the number be 168; in the second radius between 1 and 2, seek the sixth of the larger subdivisions, and the point will fall between this sixth and the seventh of the subdivisions, and the true point will be on the eighth of the smaller ones, which will represent the number 168; the like division in the first radius represents 16.8; but if this stood for 168, then the like division in the second radius stands for 1680.

To find a fraction, consider that the line properly only expresses decimal fractions, as thus, $\frac{1}{10}$, or $\frac{1}{100}$, or $\frac{1}{1000}$, and nearer the rule cannot well come than one inch, one tenth, one hundredth, or one thousandth part of an inch: so that for other fractions, as quarters, half quarters, &c. you must either estimate them as near as you can reasonably, or else reduce them into decimals.

Use of GUNTER'S LINE. 1. Two numbers being given, to find a third geometrically proportional to them; and to three a fourth number, to a fourth, a fifth, &c. Extend the compasses on the line from one number to another; then if that extent be applied upwards and downwards, as you would either increase or diminish the number from either of the numbers, the moveable point will fall on the third proportional number required. Again, the same extent, applied the same way from the third, will give a fourth; and from the fourth, a fifth, &c.

For example: let the two numbers 2 and 4 be proposed to find a third proportional, &c. to them; extend the compasses on the first part on the line of numbers, from 2 to 4; which done, and the same extent being applied upwards from 4, the moveable point will fall on 8, the third proportional required; and from 8 it will reach to 16, the fourth proportional; and from 16 to 32, the fifth, &c. Contrariwise, if you would diminish, as from 4 to 2, the moveable point will fall on 1, and from 1 to $\frac{1}{2}$, or .5; and from .5 to .25, &c.

But generally in this, and in most other works, make use of the final divisions in the middle of the line; that you may the better estimate the fractions of the numbers you make use of; for how much you miss in setting the compasses to the first and second term, so much the

more

more you will err in the fourth; therefore the middle part will be most useful. For example, as 8 to 11, so 12 to 16.5, if you imagine one integer to be divided into ten parts, as they are on the line on a two-foot rule. See *SLIDING-RULE*.

2. One number being given to be multiplied by another, to find the product. Extend the compasses from 1 to the multiplier; and the same extent, applied the same way from the multiplicand, will make the movable point fall on the product; thus, if 6 be given to be multiplied by 5, extending the compasses from 1 to 5, the same extent will reach from 6 to 30, the product sought.

3. One number being given to be divided by another, to find the quotient. Extend the compasses from the divisor, e.g. 25, to 1, and the same extent will reach from the dividend, e.g. 750, to the quotient 30; or extend the compasses from the divisor to the dividend, the same extent will reach the same way from 1 to the quotient.

4. To reduce a vulgar fraction into a decimal. In this case, the denominator of the given fraction is to the numerator as 1 is to the decimal required: let the fraction be $\frac{7}{3}$, extend the compasses from 8 to 7, and this extent laid the same way from 1 will reach to .875 the required decimal.

5. Three numbers being given, to find a fourth in direct proportion. Extend the compasses from the first number, suppose 7, to the second, v.g. 21: that done, the same extent, applied the same way from the third, 20, will reach to the fourth proportional sought, viz. 44, which is the circumference of a circle, whose diameter is 28, by Archimedes's proportion.

6. Three numbers being given, to find a fourth in inverse proportion. Extend the compasses from the first of the given numbers, suppose 60, to the second of the same denomination, viz. 30; if that distance be applied from the third number backwards, 5, it will reach to the fourth number sought, 4.5.

7. Three numbers being given, to find a fourth in duplicate proportion. If the denominations of the first and second terms be lines, extend the compasses from the first term to the second, of the same denomination: thus done, that extent being applied twice the same way from the third term, the movable point will fall on the fourth term required. E.g. the area of a circle, whose diameter is 1, being .78539, what will the content of a circle be, whose diameter is 28? Apply the extent from 1 to .78539, the same way from .785 twice, the movable point will fall on 640, the fourth proportional or area sought.

8. Having three numbers given, to find a fourth in triplicate proportion. In this case the first and second terms must be always in the same denomination: e.g. If an iron-bulb of 4 inches diameter, weighs 9 pounds, what is the weight of another of the same metal, whose diameter is 6 inches? the extent from 4 to 6, laid on three times from 9 will reach to 30 3/4 pounds.

9. To find a mean proportional between two given numbers. Bisect the distance between the two given numbers, the point of bisection will fall on the mean proportional sought. Thus the quotient of the two extremes divided by one another, extremes being 8 and 32, the middle point between them will be found 16.

10. To find two mean proportionals between two given lines. Trisect the space between the two given extremes; the two points of trisection will give the two means required; thus, if 8 and 27 be the two given extremes, the two means will be found 12 and 18.

11. To find the square-root of any number under 10000000. The square root of a number is always a mean proportional between 1, and the number whose root is required; yet with this general caution, that if the figures of the number be even, that is 2, 4, 6, 8, 10, &c. then you must look for the unit at the beginning of the line, and the number in the second part or radius, and the root in the first part; or rather, recede to the end to be unity; and then both root and square will fall backwards towards the middle in the second length or part of the line. If they be odd, the middle 1 will be most convenient to be counted unity, and both root and square will be found from thence forward towards 10. On this principle the square root of 9 will be found to be 3; the square root of 64, to be 8, &c.

12. To find the cube root of any number under 1000000000. The cube root is always the first of two mean proportionals between 1 and the given number, and therefore to be found by trisecting the space between them. Thus the cube root of 1027 will be found 10; the root of 17280, nearly 26; the root of 172800 almost 56.

Though the point on the line representing all the square numbers is in one place, yet, by shifting the unit, it produces various points and numbers for their respective roots. The rule to find this is, to put dots, or to sup-

pose them put, over the first figure to the left hand, the fourth figure, the seventh, and the tenth: if then the last dot on the left-hand falls on the last figure, as it does in 1728, the unit must be placed at 1 in the middle of the line, and the root, the figure, and the cube, will all fall forward to the end of the line.

If it fall on the left but 2, as in 17280, the unit must be placed at 1 in the beginning of the line, and the cube in the second length; or the unit may be placed at 10 at the end of the line, and then the root, the square, and cube, will all fall backwards, and be found in the second part between the middle and end of the line. Thus will the cube root of 8 be found 2; and that of 27, 3; that of 64, 4; that of 125, 5; that of 216, 6, &c.

We may observe in general, with regard to these two last problems, that the line of numbers is only a line of logarithms, and any logarithm divided by 9, quotes the logarithm of the square root of its natural number; if divided by 3, it gives the logarithm of the cube root, and if by 6, it gives the logarithm of the sixth power, &c. Hence the roots of all powers may easily be found on the line of numbers, by dividing the distance or extent on the scale, between unity and the number given to be extracted, into as many equal parts as are directed by the index of that power, i.e. the figure into 2 equal parts; the cube into 3; the biquadrate into 4, &c. which half, third, fourth, &c. part, taken in the compasses and laid off from unity (observing well the notation, or value of the figures) will give the respective root required.

For the particular use of Gunter's line in the measuring of timber, gauging of vessels, &c. See *SLIDING-RULE*. For other uses in geometry, trigonometry, &c. See *SECTOR*, and *GUNTER'S* scale.

GUNTER'S quadrant is a quadrant made of wood, brass, or some other substance; being a kind of stereographic projection on the plane of the equinoctial, the cyclo represented in one of the poles: so that the tropic, ecliptic, and horizon, form the arches of circles, but the hour-circles all curves, drawn by means of several altitudes of the sun, for some particular latitude every day in the year.

The use of this instrument is to find the hour of the day, the sun's azimuth, &c. and other common problems of the globe; as also to take the altitude of an object in degrees.

See in description and use more at large under the article *GUNTER'S QUADRANT*.

GUNTER'S scale, also called by navigators absolutely, *The Gunter*, is a large plain scale, with divers lines thereon, of great use in working questions in navigation, &c. See *SCALE* and *SAILING*.

This instrument derives its name from its inventor, Mr. Edmund Gunter, who was professor of astronomy in Gresham college, and first published the scales of logarithms, numbers, lines, and tangents, in his description of the cross-staff, in 1624. The errors which had crept into Gunter's scale, by length of time and negligence in the fabrication of it, have been corrected by the late Mr. John Robertson, librarian to the Royal Society, and the instrument has been reconstructed, under his inspection and with his improvements, by Messrs. Nairne and Blunt, mathematical instrument makers in London. See a description of this instrument in its improved state by W. Mountain, F.R.S. published in 1778.

On one side of the scale, represented *Tab. Trigonometry*, fig. 1. are the lines of numbers, marked *numeri*; the line of artificial lines, marked *lineæ*; the line of artificial tangents, marked *tangentes*; the line of artificial versed lines, marked *V. S.* the artificial sines of the rhumbs, marked *S. R.* the artificial tangents of the rhumbs, marked *T. R.* meridian line in Mercator's chart, marked *Africa*, and equal parts, marked *E. P.*

To which on the thicker scales of a foot long, are usually added lines of latitudes, hours, and inclinations of meridians. On the backside of the scale are the lines usually found on a plain scale.

The lines of artificial lines, tangents, and numbers, are so fitted on this scale, that by means of a pair of compasses, any problem, whether in right-lined or spherical trigonometry, may be solved very expeditiously, and with tolerable exactness; whereas the instrument becomes extremely useful in all parts of mathematics where *TRIGONOMETRY* is concerned, as navigation, dialling, astronomy, &c.

The same lines are also occasionally laid down on rulers to slide by each other; hence called *sliding Gunter's*, so as to be used without compasses; but he that understands how to use them well, may, by what we have said of Brevard's and Coggeshall's sliding rules, use them without. See *SLIDING-RULE*.

The *Gunter's scale*, as it has been lately improved, is made 30 inches long, 2 inches broad, and about half

half an inch thick. One face contains the natural scales; half the length of this face is filled with scales of equal parts, which are denominated by the divisions of an inch, viz. scales of 10, 12, 15, 20, 25, 30, 35, 40, 45, 50, and the left-hand primary division of each scale is divided into 10 equal parts, and also into 12 equal parts: on the other half of this face are put the several lines which constitute the *plain scales*, such as the scales of rhumbs, chords, fines, secants, tangents and half-tangents, fitted to a radius of 2 inches; also the dialling scales, viz. inclination of meridians, latitudes, chords, and hours, to a radius of 2 inches; and a scale of chords and miles of longitude to a radius of 3 inches, and other scales of chords and rhumbs to a radius of 1 inch. The breadth of the other face, which contains the logarithmic scales, is divided into 12 parts, or scales running nearly the whole length; nine of these scales may be called fixed, and the other three moveable, being on a sliding piece of about 30 inches long, 1 inch broad, and of the thickness of the scale. The order of these scales, or lines is—

Fixed	1. A line of fine rhumbs, marked	S. R.
	2. A line of tangent rhumbs, marked	T. R.
	3. A line of versed fines, marked	V. S.
	4. A line of fines, marked	Sin.
Sliding	5. A line of fines, marked	Sin.
	6. A line of numbers, marked	Nam.
	7. A line of tangents, marked	Tan.
	8. A line of tangents, marked	Tan.
	9. A line of numbers, marked	Nam.
	10. A line of meridian degrees to 50, marked	Mer.
Fixed	11. A line of meridian degrees from 50 to about 74, marked	Mer.
	12. A line of degrees of longitude, marked Lon.	

Along this face an index or thin piece of brass, about an inch broad, is contrived to slide, which going across the edge of the scales at right angles to it, will show on the several lines the divisions which are opposite to one another, although the lines are not contiguous. The apparatus at the right hand consists of a brass box and two screws; the slider passes freely through the box, when the perpendicular screw is eased and may be readily set by hand to the terms given; but for greater accuracy, and in order to keep the slider in its true position, move the perpendicular screw, which by a sub-spring will fix the slider in the box, and then by the motion of the horizontal screw, the greatest degree of accuracy possible may be obtained. Compasses may be used with this scale, as well as with the common Gunter's, by first bringing the radius on the slider exactly in a line with the others on the right hand and fixing it there. In a convenient part of this instrument are marked 10 feet each, each of which contains 13,824 English inches, and each foot is divided into 12 equal parts, called sea-inches. The method of forming and graduating the several lines on Gunter's scale is as follows: the construction of the line of numbers has been already explained; for the line of logarithmic fines, it is to be observed, that this line terminates at 90 degrees, just against the 10 at the end of the line of numbers; and from this termination the degrees are laid backwards, or from thence towards the left; in order to obtain divisions answering to them, seek in a table of logarithmic fines the numbers expressing the ARITHMETICAL complements of the several degrees, without the index, take these numbers from the scales of equal parts by which the line of numbers was formed, and apply them to the scale of lines from 90°. Then the arithmetical complements of the logarithmic fines (or the cosecants) abating the index, of 10°, 20°, 30°, 40°, &c. are the numbers 70033, 45055, 30103, 19103, &c. and the equal parts answering to these numbers will give the divisions for 10°, 20°, 30°, 40°, &c. and proceed in the same manner for the intermediate degrees. The arithmetical complement of the line of 50° 44' 21" will be equal to 10 of the primary divisions of the scale of equal parts, or to one interval in the logarithmic scale: so that a decrease of the index by unity answers to one interval; then a decrease of the index by 2 answers to 2 intervals, or the whole length of the logarithmic scale, which happens at the line of 0° 34' 22", and the divisions answering to the line of a half above 3, viz. 3° 22", will be equal to 3 intervals, and the line of 21" will be a 4 interval, and therefore all the lines between 90° and 0° 34' are those only, which can be put on this scale, the lesser lines extending beyond this length. It has been usual to insert the divisions to every 5°, as far as 10°; from 10° to 30°, the small divisions are made 15' each; from 30° to 50°, every half degree is marked; from 50° to 70° only the whole degrees. On the improved scale the space between 90° and 80° is too small to admit of more than five divisions; that nearest to the 90° being

VOL. II. N° 162.

the mark for 8½°; between 80° and 60°, the divisions are single degrees; from 60° to 50° every degree and half degree are introduced; from 50° to 30° are degrees and third-parts, or every 20' from 30° to 20° are degrees and quarters, or every 15'; and from 20° downwards are put in the degrees and sixth parts of degrees. This line of fines is put the uppermost of the 3 on the slider, and also the lower on the upper part of the fixed scales, whereby the 2 scales of fines are contiguous.

For the line of tangents, it is evident, since the tangent of 45° is equal to the radius, or line of 90°, that 45° on this scale will terminate directly opposite to 90° on the line; and the several divisions of this scale of logarithmic tangents are constructed in the same manner as those of the fines, by applying their arithmetical complements backwards from 45° or towards the left hand. The degrees above 45° are to be counted backwards on the scale; thus, the division at 40, represents both 40° and 50°, &c. In the new scale this line defends as low as 0° 34' on the line; the space between 10° and 45°, and back again from 45° to 80°, are large enough to admit of 4 spaces in each; and therefore, the subdivisions between 10° and 80° extend to every 15 minutes; but the degrees under 10 and above 80 are each subdivided into 6 parts, or to minutes each. This line of tangents is, like that of fines, laid down twice on the new Gunter's, once on the slider and once on the lower fixed part. The construction of these lines of fines and tangents, above explained, depends on the following theorems in trigonometry: 1. The cosine is to the radius as the radius is to the secant. 2. The sine is to the radius as the radius is to the cosecant. 3. The tangent is to the radius as the radius is to the cotangent. From these theorems it appears, that, if the radius of the tables be supposed equal to 1, in either of the above cases, one of the quantities will be equal to the quotient of unity divided by the other; but division is performed by subtraction with logarithms, and the subtraction of a logarithm is the same as the addition of its arithmetical complement; consequently, the logarithmic cosine and secant of the same degrees are the arithmetical complements of one another; and, as the arithmetical complement of any number is what that number wants of unity in the next superior place, every natural fine and its arithmetical complement are together equal to radius. Therefore, since the fines begin at one end of the radius and terminate in 90° at the other end, in a scale of fines, the arithmetical complement of any fine or its cosecant, laid backwards from 90°, gives the division for that fine; and the scale will be the same in a scale of logarithmic fines. And as the logarithmic tangents and cotangents are the arithmetical complements of one another, the divisions to the degrees both under and above 45, in a scale of logarithmic tangents, are equally distant from the division of 45°; consequently the divisions serving for the degrees under 45 will serve, by reckoning backwards, for those above 45.

For the versed fines: from the scale of equal parts take the arithmetical complements of the logarithmic cosines, or the secants of the complements, of 5, 10, 15, 20, 25, 30, &c. degrees, rejecting the indices; and the double of these distances will give the divisions, on the proposed scale of versed fines, expressing 10, 20, 30, 40, 50, 60, &c. degrees, continued and divided according to the length of the scale; otherwise, having a table of logarithmic versed fines to 180°, subtract each logarithmic versed fine from that of 180 degrees, and lay the remainders successively taken from the scale of equal parts on the ruler backwards from the common termination. This line of versed fines begins at 0°, and runs thence towards the left hand to about 168°, one extremity of this line has the same termination with the lines of numbers, fines and tangents, where the mark for 180° should be placed; but as the scale begins at this place, and the divisions may be supposed to go backwards, therefore 0 is put for the beginning, and the numbers thence proceeding through 10, 20, &c. towards the left are only the supplements of the versed fines themselves.

On the new scale, the divisions under 10° fall too close to one another to be distinguished; from 10° to 60° every single degree is introduced; from 60° to 100°, every degree and half degree; from 100° to 130° every degree and third of a degree; from 130° to 150° every degree and quarter of a degree; and above 150° every degree and sixth part of a degree.

The construction of the lines of fine rhumbs and tangent rhumbs is easily understood; as these are formed by taking the fines and tangents of the degrees and minutes answering to the rhumbs and parts of rhumbs from the lines of fines and tangents respectively, and laying them down on their proper scales.

The scale of longitude is also a line of equal parts representing

finding the lengths of degrees of longitude, or of the degrees taken on the equator, in which the reckoning of a ship's longitude at sea is kept; each degree, in the new scale, being about half an inch, and subdivided into ten parts of six minutes each.

The scale of meridional degrees is formed from the preceding, and shows the length of the degrees of latitude, relative to the correspondent degrees of longitude; the degrees being gradually increased in the same proportion as the degrees of longitude on the globe diminish from the equator towards either pole; and each of them is subdivided into ten parts of six minutes each.

This scale comprehends, in the improved Gunter, two lengths of the ruler; the first length extends from the beginning at 0° on the right, and proceeds thence towards the left as far as 50°; and begins again on the right-hand at 50°, and goes on to the left as far as 75°, which is as far as most navigators extend, except those of the Greenland Fisheries.

GUNTER'S RULE, &c. &c. 1. *The half of a right-angled, right-angled triangle being given, 50 miles, and the angle opposite thereto 25 degrees, to find the length of the hypotenuse.* The trigonometrical canon or proportion is thus: as the sine of the angle, 20 degrees, is to the base, 30 miles, so is the radius to the length of the hypotenuse. Set one foot of the compasses, therefore, on the 20th degree of the line of the sines, and extend the other to 30 on the line of numbers; and the compasses remaining thus opened, set one foot on 90 degrees, or the end of the line of sines, and extend the other on the line of numbers; this will give 68 miles and a half for the length of the hypotenuse sought.

2. *The base of a right-angled triangle being given, 25 miles, and the perpendicular 15, to find the angle opposite to the perpendicular.* As the base, 25 miles, is to the perpendicular, 15 miles, so is the radius to the tangent of the angle sought. Extend the compasses, then, on the line of numbers, from 15, the perpendicular given, to 25, the base given; and the same extent will reach the contrary way, on the line of tangents, from 45 degrees to 31 degrees, the angle sought.

3. *The base of a right-angled triangle being given, suppose 20 miles, and the angle opposite to the perpendicular 50 degrees, to find the perpendicular.* As radius is to the tangent of the given angle, 50 degrees, so is the base, 20 miles, to the perpendicular sought. Extend the compasses then on the line of tangents, from the tangent of 45 degrees to the tangent of 50 degrees; and the same extent will reach on the line of numbers the contrary way, from the given base, 20 miles, to the required perpendicular, 23½ miles.

Note, the extent on the line of numbers is here taken from 20 to 23½ forwards; that the tangent of 50 degrees may be at least beyond the tangent of 45 degrees, as its complement 40 degrees wants of 45 degrees.

4. *The base of a right-angled triangle being given, suppose 35 miles, and the perpendicular 48 miles, to find the angle opposite to the perpendicular.* As the base, 35 miles, is to the perpendicular, 48 miles, so is radius to the tangent of the angle sought. Extend the compasses from 35 on the line of numbers to 48, the same extent will reach the contrary way on the line of tangents, from the tangent of 45 deg. to the tangent of 36 deg. 5 min. or 53 deg. 55 min. To know which of those angles the angle sought is equal to, consider that the perpendicular of the triangle being greater than the base, and both the angles opposite to the perpendicular and the base making 90 deg. the angle opposite the perpendicular will be greater than the angle opposite to the base; and consequently the angle, 53 deg. 55 min. will be the angle sought.

5. *The hypotenuse of a right-angled spherical triangle being given, suppose 60 degrees, and one of the sides 20 degrees, to find the angle opposite to that side.* As the sine of the hypotenuse 60 deg. is to radius, so is the sine of the given side 20 deg. to the sine of the angle sought. Extend the compasses on the line of sines from 60 deg. to the radius, or 90 deg. and the same extent will reach on the line of sines the same way, from 20 deg. the given side, to 22 deg. 10 min. the quantity of the angle sought.

6. *The course and distance of a ship being given, to find the difference of latitude and departure.* Suppose a ship sails from the latitude of 50 deg. 10 min. north, S.S.W. 48.5 miles; as radius is to the distance sailed 48.5 miles, so is the sine of the course, which is two points, or the second rhumb from the meridian, to the departure. Extend the compasses from 5° or 90 deg. on the artificial fine rhumb-line to 48.5 on the line of numbers, the same extent will reach the same way from the second rhumb, on the line of artificial lines of the rhumbs, to the departure wanting 18.6 miles.

Again, as radius is to the distance sailed 48.5 miles, so is the cosine of the course 67 deg. 30 min. to the differ-

ence of latitude. Extend your compasses from the radius, on the line of sines, to 48.5 miles on the line of numbers; the same extent will reach the same way, from 67 deg. 30 min. on the line of sines, to 44.8 on the line of numbers which converted into degrees by allowing 60 miles to a degree, and subtracted from the given north latitude 50 deg. 10 min. leaves the remainder 40 deg. 25 min. the present latitude.

This problem may be easily solved with the slider, by setting 48.5 on the slider against 90 on the line of sines, or 8 on the line of fine rhumbs; then against two points, or 22 deg. 30 min. on the line of sines, is 18.6, the departure; and against two points on the line of fine rhumbs, or 22 deg. 30 min. on the line of sines, is 44.8 on the slider, for the difference of latitude.

7. *The difference of latitude and departure from the meridian being given, to find the course and distance.* A ship from the latitude 50 deg. north, sails north eastward till she has altered her latitude 1 deg. 10 min. or 70 miles, and is departed from the meridian 57.5 miles, to find the course and distance. As the difference of latitude, 70 miles, is to radius, so is the departure, 57.5 miles, to the tangent of the course, 39 deg. 20 min. or three points and a half from the meridian. Extend the compasses from the fourth rhumb, on the line of artificial tangents of the rhumbs, to 70 miles on the line of numbers, the same extent will reach from 57.5, on the line of numbers, to the third rhumb and a half on the line of artificial tangents of the rhumbs.

Again, as the sine of the course, 39 deg. 20 min. is to the departure 57.5 miles, so is the radius to the distance 90.6 miles. Extend the compasses from the third rhumb and a half, on the artificial lines of rhumbs, to 57.5 miles on the line of numbers; that extent will reach to the sine of the eighth rhumb, on the lines of the rhumbs, to 90.6 miles on the line of numbers.

8. *Three sides of an oblique spherical triangle being given, to find the angle opposite to the greatest.* Suppose the side A B, Tab. Trig. fig. 2, be 40 deg. the side B C 60 deg. and the side A C 96 deg. to find the angle A B C. Add the three sides together, and from half the sum subtract the greater side A C, and note the remainder; thus, *c. gr.* the sum will be 166 deg. half of which is 83 deg. from which subtracting 96 deg. the remainder is 2 deg.

Then extend the compasses from the sine of 90 deg. to that of the side A B 40 deg. and applying this extent to the sine of the other side B C 60 deg. you will find it reach to a fourth sine 34 degrees.

Again, from this fourth sine extend the compasses to the sine of the half sum, *i. e.* the sine of 73 deg. the supplement of 98 deg. to 180; this second extent will reach from the sine of the difference 2 deg. to the sine of 3 deg. 24 min. against which, on the vertical lines, stand 151 deg. 50 min. the quantity of the angle sought.

GUNWALE, or **GUNNEL** of a ship, is that piece of timber which reaches on either side of the ship, from the half-deck to the fore-castle, being the uppermost bend, which finishes the upper works of the hull in that part, and wherein they put the stanchions which support the waste-trees. This is called the *gunwale*, whether there be guns in the ship or not. The lower part of any port, where any ordnance are, is also termed the *gunwale*.

GUR, or **GURRA**, in *Mineralogy*, a word used to express a fluid matter looking like milk, but reduced sometimes, by evaporation, to the consistence of honey, and appearing in form of a white sediment. It is common in the mines of Sweden, and in some other places; it is sometimes calcareous or chalky, and sometimes metallic, and by dropping forms flaccid concretions. Bromell. de Lapid.

GURGEATIO, a name by which some authors have called that peculiar disease so fatal in England at one time, and commonly called *suppur. Angina*, from the violent profusions of sweat which appeared immediately on being seized with it.

GURGIPTING, in *Falconsry*, a term used when a hawk is stiff and choked up. Dict. Rust.

GURGULO, in *Natural History*, a name given by the ancients to a peculiar class of *furax* or beetles; the characters of which are, that they have not a short head like the other beetles, but a long one, forming a trunk in the manner of the common bee; in this the horns or antennae of the creature are lodged. These are divided by Lister into two kinds; the one having only one joint in this promissory or snout, and that placed in or near the middle, the other having several placed near the end. Of the first kind we have only two species. Of the other kind, in which the promissory has several joints at the end, we have five species; and in all these, as well as in the former, the antennae are inserted in the promissory.

GURNARD, a sea fish, of which there are several species.

The

The characters are, that they have a sloping nose; a head covered with strong bony plates, seven branchiostegous rays, and three slender appendages at the base of the pectoral fins; and it is added that they can make a sort of noise; hence the Latins called them *mulii*, from their imitating, in some sort, the voice of the cuckoo.

The English *gunard*, which is their common name, seems also taken from their grunting; and one species of them is called the *piper*, *ayra*, or the *musician*, from its resembling with its voice a small pipe.

GUNARD, the *grey*, or *TRIGLA gunardus* of Linnaeus, is the most common kind; it is frequent in the British seas and elsewhere, and esteemed a very well-tasted fish. This is of a long slender shape; its back is of a dusky green marked with black spots, and with yellow and white ones; the side-lines are dotted and rough; under these the sides are of a pale colour, and variegated with numerous white spots; the belly is white; the head is large, and is covered with a sort of bony plates, the upper one of which runs out behind into two sharp prickles; the front has also two horns, each having three little horns or teeth, and there are also two others before each eye; the mouth is large, and the teeth very small; its gill-fins are not so large as in many others of this kind; and its back has a cavity between two rows of pointed bones: the tail is bifurcated. This fish, which bites eagerly at a red rag, is usually taken with the hook in deep water; but it is found sometimes sporting near the surface. They are often caught of the length of two feet and a half.

GUNARD, the *red*, is an English name given to the *TRIGLA cavius* of Linnaeus, called by authors in general the *cavius*, and by some *ayra*, *ayra*, and *ayra*. It is properly a species of trigla, according to the new Artedean system, and is distinguished from all the other species, by the name of the wholly red trigla with the snout highly divided into two horns, and the opercula of the gills fringed. This is an instance of the value of the Artedean names, this conveying to good an idea of the fish, that it cannot be mistaken, and the others conveying none at all. See *Tab. of Fishes*, N° 9. This red species is what we sometimes simply call the *gunard*, and sometimes the *raichet*.

GUNARD, *sapphirina*, *trigla hirundo* of Linnaeus, or *trigla*, is distinguished from the other species of *gunard* by the breadth and colour of the pectoral fins, which are very broad and long, of a pale green, most beautifully edged and spotted with rich deep blue. The dorsal fins are lodged between two rows of spines, of a serrated form; the back is of a greenish cast: the side-line is rough; the sides are tinged with red, and the belly white; the pupil of the eye is green, and on the inner corner of each are two small spines. These fish are found on the coast of Cornwall.

GUNARD, *ylina*. See *DRACUNCULUS*.

GUROUNDI, in *Ornithology*, the name of a small Brazilian bird, frequently kept in cages for its singing, and more commonly called *TRITE*.

GUSSET, in *Heraldry*, denotes one of the ABATEMENTS of honour, appropriated to lascivious, effeminate, or wanton persons. It is formed of a line drawn from the dexter or sinister angle of the chief, and descending diagonally to the chief point; from whence another line falls perpendicularly upon the base: as represented *Tab. II. Herald.* fig. 67.

GUST. See *TAUST*.

GUIT is used by Bracton, and other ancient writers, for stranger or guest, who lodges with a person the second night. See *UNCUT*.

In the laws of St. Edward, published by Lambard, the word is written *gyl*.

GUST denotes a sudden and violent squall of wind, bursting from the hills upon the sea, so as to endanger the shipping near the shore. These are peculiar to some coasts, as those of South Barbary and Guinea.

GUSTATION. See *TASTING*.

GUSTO grand. See *GRAND*.

GUTS. It is observed, in the dissections of many of the beasts of prey, that the *guts* are very remarkably short in comparison of those of other animals. The lion and the lynx are of this number; the *guts* being in these only of three times the length of the body. This argues speedy digestion, and a great voracity of the creature. See *INTESTINES*.

GUTTA, a Latin term for what in English we call *DROP*.

GUTTA Angliana, *English drops*, *volatile English drops*, or *Goddard's drops*, a name of a medicinal liquor prepared from divers ingredients, formerly supposed to be of sovereign efficacy against coagulations of the blood, malignant fevers, and particularly the *missus-pox*, obstructions, epilepsies, drowsy diseases, vapours, &c.

The inventor of these celebrated drops was Dr. Goddard,

a physician of London. The secret of their composition was purchased by King Charles II. at the price of 40,000. sterl. whence they were denominated *gutta Angliana*. This costly receipt we shall here gratify the reader with a *secretum machi*: "Take five pounds of human cranium, of a person hanged, or dead of some violent death, two pounds of dried vipers, two pounds of hart's-horn, and two of ivory; mince the whole small, put it in two or three terriers, and distill it in a reverberatory furnace, with the same precautions as are ordinarily used in distilling hart's-horn and vipers, to extract their volatile salt. When the vessels or receivers are cold, untie them, and shake them well, in order to loosen the volatile salts from the sides of the vessels. Pour the whole in a large glass cucurbit, and filtrate it through a brown paper, in order to separate the oil which is here useless: put the filtrated liquor in a glass retort, and place it in a sand heat, and fit another glass retort thereto, as a recipient; take care all things be well luted, and make a colubation of the said matter at three times. But, by the way, add all the salt before separated from the receivers; and after the said three colubations, untie the retorts, and pour the whole into a matrass with a long neck, to which fix a suitable capital, and a receiver; lute all the joinings on each side with a wet bladder, and let the vessel in a sand-heat: by this means, the volatile salt will be sublimed, and stick to the capital and upper part of the matrass. Continue the fire till a faint enough hath risen to sale and dissolve the salt which arose first: then take all the fire out of the furnace, that the distillation may proceed no farther, which is a circumstance of the last importance, without which the medicine would be weakened by too much phlegm." Bier, in *Mem. de Trev.* 1713.

As to the dose of this remedy, they begin with seven or eight drops, increasing by degrees to forty or fifty, on pressing occasions, as in apoplexies, lethargies, weaknesses, &c.

The real composition of the *gutta*, however, is somewhat controverted. Dr. Lister assures us, that he had the secret communicated to him by King Charles II. that it is no other than the volatile spirit of raw silk, redified with oil of cinnamon, or some other essential oil. The same author assures us, he had found by experience, that the *gutta Angliana* were not in any respect preferable to the common volatile spirits of hartshorn and sal ammoniac, except that the smell is more supportable. *Mem. de l'Acad. des Sciences* ann. 1700.

GUTTA, in *Architecture*, are ornaments of form in little cones, in the plafond of the Doric cornice, on the architrave, underneath the triglyphs, representing a sort of drops or bells; they are usually six in number. See *Tab. Archit.* fig. 25. N° 12.

They are sometimes also called *lucryme*, *tears*; and *campane* or *campanule*, *bells*. Leon Baptista Alberti calls them *nauli*.

GUTTA rasata, in *Medicine*, denotes a red or pimples face; a dis temper, which, though not always owing its original to hard drinking, is nevertheless most incident to tipsers of strong beer, wines, spirits, &c.

As to the cure, besides making a revulsion by bleeding, blistering, cupping, issues, &c. the diet ought to be moistening and cooling, as lettuce, purslain, sorrel, and spinach: the drink may be an emulsion of the cold seeds milk and water, clarified whey, &c.

In the use, however, of this cooling regimen, great caution is necessary; for if a person be taken off at once from his strong liquors, and allowed nothing but whey, or milk and water, it may cost him his life, by hastening a sudden decay of heat, pulling his appetite, and bringing on a leucophlegmia or dropsy.

As for what concerns topics, much caution is likewise to be used. If there be only redness without pimples, and the disease recent, refrigerants and repellents take place; but if pustules appear, disinctants must be mixed; and if these pustules seem hard, and the disease be of long standing, there may be reason for emollients to ripen and digest the tough and viscid matter, which is afterwards to be let out.

If the disease be stubborn, and the tubercles grow hard, we are to begin with emollients, both lotion and ointment: such are the decoction of mallows, vervain, Solomon's seal, and linseed; also a cerate of spermaceti, or Bala's white cerate. James.

GUTTA SERENA, so called from the transparency of the several humours of their membranes, is a disease of the eyes, being an entire privation of sight, without any apparent fault, or disorder of the part, excepting that the pupil looks somewhat larger and blacker than before.

This disorder is most commonly, but not universally, attended with a dilatation of the pupil; so that every dilated

lated pupil is not a certain sign of this disease. Scrophulous subjects have often very dilated pupils, with little or no defect of sight; but in them the pupils preserve their motion; the loss of which motion, says Mr. Warner, is a more certain sign of a *gutta serena* than dilatation of the pupils. The Greeks call it *amaurosis*. This disorder is either *transient* or *permanent*.

The *transient gutta serena* is that found in apoplexies and lipothymias, from immoderate bleeding, and the like, which vanishes as the fit of apoplexy goes off. To this kind also belong those sometimes produced by the suppression of the hemorrhoids, menies, or other habitual evacuations, the healing up of ulcers, or the like.

The *permanent* is that whose cause is fixed in the retina, or in the optic nerves; chiefly in the want of the clear interoptic and inflex between the brain and those parts. To this kind also belong those occasioned by hydrocephalus, by fibres found near the root of the optic nerves, or by leucimas compressing those nerves, or by debilities and extenuations, by convulsions and compressions of the same at their issue out of the cranium.

The proximate cause is, according to Hoffman and other eminent physicians, a palsy of the optic nerves.

The mediate causes of this disorder may, as in other nervous cases, be referred to two kinds, repletion and imaction.

To the first belong all such causes as increase the blood too much, or force it with too much violence into the head. Thus, too great motion, immoderate hot bathing, violent fits of anger, deficiency of the menies, and spasms in the lower parts, forcing the humours upwards, as it sometimes happens to women in labour, and by vomit. All these causes, as also the repulsion of humours appearing on the skin, and drying up of ulcers, the translation of morbid matter in malignant fevers, small-pox, or phreisy, and the improper use of mercurials, have been known to bring on a *gutta serena*; sometimes, indeed, only transitory, and sometimes curable by evacuations, as bleeding, &c.

To the second kind belong all immoderate effusions of the vital juices. Thus, great hemorrhages, bloody vomits, profuse bleeding, and, above all, early and immoderate venery, have been observed to produce *BLINDNESS*, extremely difficult, if not impossible, to cure. See Hoffm. Oper. tome iii. p. 228. seq.

The *gutta serena*, is one of the most dangerous and untractable of all diseases of the eyes. The symptoms of this disease, in its incipient state, and of a cataract, much resemble one another: they are alike indicated by a head ache, situated near the forehead; by a dimness of sight, as if glass were placed before the eyes; by the loss of motion being before the eyes; and by the multiplication of objects.

The *gutta serena* admits of no operation on the eye itself, but when the cause is recent and partial, evacuations of blood from the temporal arteries, by leeches or the lancet, from out of the external jugular veins, or from a vein of the arm, joined with weak purgatives, are advisable. Blisters on the head are likewise to be recommended; or an issue made by caustics on the coronal suture, where it joins with the facial, if blisters do not succeed to our wishes. Strong decoctions in water of equal parts of Peruvian bark and valerian root in powder, joined with volatile salts, administered in pretty large doses at proper intervals, are often very beneficial. The oleum animale and muck have often been of great service in enervated and paralytic habits. Warner on the Eye, p. 34, &c.

The cure, according to Pitcairn, is to be attempted with mercurials, particularly calomel, and sometimes even with salivation, and with decoctions of guaiacum.

Hoffman recommends the sulphur of antimony. See AMALGAM and Mutual ELECTRICITY.

The late Mr. Ferguson contrived an instrument for applying the power of electricity to disorders in the eyes: this instrument consists of a pointed brass wire, fastened by means of a cork at the smaller end of a conical glass, open at both ends, and passing through the axis of this glass, so that its point comes within about half an inch of the larger aperture of the glass: the instrument is to be so fixed, that the larger aperture of the glass may surround the eye, and keep it hit open, and the point of the wire is directed to the pupil, and at the distance of about half an inch or an inch from it. In the use of this instrument a spark often proceeds from the point of the wire, which occasions very acute pain; and, therefore, Mr. Parrington fixed a wooden point upon the pointed wire; but the directors of this last gentleman are better advised to the purpose.

GUTTE. See GUTTES.

GUTTERS, in Building, a kind of canals in the ROOFS of buildings serving to drain, receive, and carry off the rain-water.

Gutters are either parallel to the horizon, or vertical. The former should be made with a proper descent, that there may be a good current, as the workmen term it; for if laid too level, the water will be apt to stand in places.

As to the vertical gutters, or those formed by two roofs meeting at right angles to each other, or by the end of one roof joining to the side of another, they are either made of lead or tiles, which are either plain or concave; these last are called gutter-tiles, and may be easily laid. But in laying on the plain tiles, the workman begins at one side of the gutter, and so works across, as if it were plain work, and then brings the near row of tiles back again; so that he works forth and back, to and fro, from right to left. By this means, the gutters laid after this manner are not angular, but of a kind of distorted curvilinear form, which prevents the mortar from being washed away with the rain.

GUTTER-LEDS is the name of a cross-bar, laid along the middle of a hatch-way in some ships, for supporting the covers, and any weighty body that may be laid or moved upon them.

GUTTER-TYLE. See TYLE.

GUTTETA pulvis is the name of an epileptic powder in the Paris Pharmacopoeia, composed of masticote of the oak, roots of white dittany, the root and seed of penny, of each half an ounce; the seeds of goose-foot, two drams; human skull, three drams; red coral prepared, two drams; the horns of elk's foot, half an ounce; and a scruple of gold leaf: all which ingredients are to be reduced to a fine powder. This powder has been deemed a very powerful antispasmodic, and is said to have been administered in the quantity of a scruple for a dose, for a considerable time, with great success in the epilepsy.

GUTTURAL letters, are those pronounced or formed, as it were in the throat.

Dr. Wallis distinguishes the VOWELS in our language into labial, palatine, and guttural; according to the several degrees of opening the mouth to pronounce them, larger, middle, and less. On this footing he makes three guttural vowels, and three labial, and as many palatines.

The four guttural letters in Hebrew are *ח, ט, ק, ו*, formed into the technical word *קט"ח*.

GUTTUROSUS piscis, a small fish common in the Mediterranean, and brought to market at Rome, Venice, and elsewhere; and called in different parts, *guts-fish*, *gout-torogine*, and *gutta di more*.

GUTTUS, a term among antiquaries for a sort of vase used in the Roman sacrifices, to take the wine and sprinkle it, *guttatim*, drop by drop, upon the victim.

Vignere on F. Livy gives the figure of the *guttus*, as represented on divers medals, and other ancient monuments.

GUTTY, or GUTTE, in Heraldry, is when a thing is represented as charged or sprinkled with drops.

In blazon, the colour of the drops is to be named: thus, *guty of sable*, of gules, &c.

Some authors will have red drops called *guty de sang*, or *draps of the ly*; black ones, *guty de jais*, of *pink*; white, *guty d'azur*, of *water*, &c.

GUY, in a Ship, is any rope used to keep off weighty bodies from beating or falling against the ship's side, when they are to be hoisted or lowered. Thus, if any thing is to be hoisted in over the gunwale, it is gently calked in by a *guy-rope*, fastened usually to the stanchions of the waste-trees.

GUY is likewise a large slack rope, extending from the head of the main-mast to the head of the fore-mast, and having two or three large blocks fastened to the middle of it. This is chiefly employed to sustain the tackle used for hoisting in and out the cargo of a merchant-ship, and is removed from the mast-heads as soon as the vessel is laden or delivered. See GARNET.

GUY'S hospital. See HOSPITAL.

GUZES, in Heraldry, signifies of a tawny or rusty colour.

GWADR-MERCHED, in our old Writers, a British word signifying a payment or fine, made to the lords of some manors, upon the marriages of their tenants' daughters; or otherwise, as their committing incontinency. See MARCH.

GWAE, or WAIR. See WAIR.

GYBING, in Sea language, denotes the art of shifting any boom-fall from one side of the mast to the other.

GYLPUT, in our old Writers, the name of a court-held every three weeks in the liberty or hundred of Pathbury, in the county of Warwick. *Inquisit. ad gylput dnm.* 13 Edw. III. Mount.

GYLT WHITE, in our old Writers, a composition of amendments for trespasses, &c. *Altera pro transgressionibus.* L. I. Edw. regis, anno 674. Terms of Law.

GYMNARTHIDIA, in the History of Insects, a series

or else of insects, which have soft and naked bodies furnished with limbs.

These have been generally called *exophytes*, a term expressing creatures partly of an animal, and partly of a vegetable nature; but as it is now well known that there are none such, it is proper that the term *exophyte* should no longer be retained.

Under this class are comprehended the LIMAX or the naked snail, the CERNEA, MEDDAR, APHEUDITA, AMPHITRETTA, &c.

GYMNASIARCHA, GYMNASIARCHA, compounded of *gymnasion*, and *arche*, government, in Antiquity, the master or director of a gymnasium.

The Greeks did not rank the *gymnarcha* among the number of magistrates; though his office was of great consideration, as having the care of all the youth, who were trusted to him to be formed to exercises of the body.

He had two principal officers under him, who were to assist him in the government of the gymnasium; the first named *XYSTARCHEA*, and the second *GYMNASIA*. The former was master of the *ATHLETA*, and presided over the wrestling. The latter had the direction of all the other exercises, taking care they were performed in due time and manner, that they were not too severe, that the youth attempted nothing beyond their strength, and that nothing were done that might be injurious to their health.

There had several subordinate officers or servants under them, for the service and instruction of the youth committed to them.

GYMNASIUM, a place fitted for the performing exercises of the body.

This word is *yumnasion*, formed of *younos*, naked; because they anciently put off their cloaths, to practise with the more freedom.

Among the ancients, *gymnasium* was a public edifice destined for exercise, and where people were taught, and regularly disciplined, under proper masters.

If we may credit Solon in Lucian's Anacharsis, and Cicero De Orat. lib. ii. the Greeks were the first who had *gymnasia*; and among the Greeks, the Lacedæmonians; after them the Athenians, from whom the Romans borrowed them.

There were three principal *gymnasia* at Athens; the Academy, where Plato taught; the Lyceum, noted for Aristotle's lectures; and the Cynosarges, allotted for the populace.

Vitruvius describes the structure and form of the ancient *gymnasia*, lib. v. cap. 11. They were called *gymnasia*, because the champions performed *naked*; and *palaestra*, from *pallo*, which was one of the most usual exercises there: the Romans sometimes also called them *agymna*, because the baths and bagnios made a principal part of the building.

It appears, that they did not perform their exercises quite naked, so early as the time of Homer, but always in drawers; which they did not lay aside before the thirty-second Olympiad. One Orlippus is said to have been the first who introduced the practice; for having been worsted, by means of his drawers undoing and entangling him, he threw them quite aside, and the rest afterwards imitated him.

The *gymnasia* consisted of seven members or apartments. M. Burette, after Vitruvius, recites no less than twelve, viz. 1. The exterior *porticus*, where the philosophers, rhetoricians, mathematicians, physicians, and other virtuous, read public lectures, and where they also disputed and rehearsed their performances. 2. The *apotheca*, where the youth assembled very early, to learn their exercises in private, without any spectators. 3. The *vestiary*, *apotheca*, or *gymnastrium*, a kind of wardrobe, where they stripped, either to bathe or exercise. 4. The *cellarium*, *apotheca*, or *cellarium*, appointed for the unclothed, which either preceded or followed the use of the bath, wrestling, pancratis, &c. 5. The *cellarium* or *cellula*, in which they covered themselves with sand or dust, to dry up the oil or sweat. 6. The *palaestra*, properly so called, where they practised wrestling, the pugilatus, pancratis, and diverse other exercises. 7. The *peristylum* or tennis-court, reserved for exercises where they used balls. 8. Large unpaved alleys, which comprehended the space between the porticoes and the walls wherewith the edifice was surrounded. 9. The *agali*, which were porticos for the wrestlers in winter or bad weather. 10. Other *agali* or open alleys, allotted for summer and fine weather, some of which were quite open, and others planted with trees. 11. The *narthex*, consisting of several different apartments. 12. The *stadium*, a large space of a semicircular form, covered with sand, and surrounded with seats for the spectators. For the administration of the *gymnasia*, there were divers

Vol. II. N° 162.

officers: the principal were, 1. The *gymnarcha*, who was the director and superintendent of the whole. 2. The *xystarchea*, who presided in the *agali* or stadium. 3. The *gymnasiarcha*, or master of the exercises, who understood their different effects, and could accommodate them to the different complexions of the athletes. 4. The *pedagogue*, whose business was mechanically to teach the exercises, without understanding their theory or use. Under these four officers were a number of subalterns, whose names distinguished their different functions. For the kinds of exercises practised in the *gymnasia*, they may be reduced to two general classes, as they depend either on the action of the body alone, or as they require external agents or instruments. The former are chiefly of two kinds, *erectus* and *palaestra*.

The *erectus* comprehended, 1. *Dancing*. 2. *Cubistia*, or the art of tumbling. 3. *Sphæristia* or tennis, including all the exercises with pile or ball.

The *palaestra* comprised all exercises under the denomination *palaestra*; as, 1. *Wrestling*, *boxing*, *pugilatus*, *hoplomachia*, *running*, *leaping*, *throwing the discus*, the exercise of the javelin, and that of the hoop, denominated by the Greeks *xystris*, which consisted in rolling an iron hoop five or six feet in diameter, beset with iron rings, the noise of which appalled the people to give way, afforded them also an amusement. Both strength and skill were requisite in directing this hoop, which was to be driven with an iron rod.

To these must also be added, the exercises belonging to the medicinal gymnastics; as, 1. *Walking*. 2. *Pacificatio*, or shouting. 3. *Holding out the breast*.

The bodily exercises, which depend on external agents, may be reduced to *manu*, the horse, riding in a chaise, or other wheeled vehicle; *radia* in beds or cradles, and sometimes *puingia*; to which may be added, the art of *swimming*. Hoffman enumerates no less than fifty-five sorts of *gymnastic* exercises.

GYMNASTES, *gymnastes*, among the Ancients, an officer in the ancient *gymnasium*, next in authority to the *gymnarcha* and *xystarchea*.

GYMNASIUM, *gymnasion*. See GYMNASIUM.

GYMNASTICKS, GYMNASIOTICS, or the GYMNASIAC ART, denotes the art of performing exercises of the body, whether for defence, health, or diversion.

The *gymnastic* art is divided into three species or branches; *military*, *nautic*, and *athletic* or *gymnastic*.

Several modern writers have treated of this art; as Mercatorius, De Arte *Gymnastica*; Faber, in Agonistia; Joubert, De *Gymnastica*; Cagnani, De *Stim. Tuend. Vellus*; De Quatuor Artib. *Populæ*; Meursius, De *Orchestra*; Fuller, in *Medicina Gymnastica*; and M. Burette, in several Dissertations on the ancient Dancing, Sphæristics, Athletics, Wrestling, Pugilatus, Discus, &c.

M. Burette has given the history of *gymnastica* in the Memoirs of the Royal Academy of Inscriptions. According to him, this art is coeval with the world. In reality, we can hardly suppose mankind to have ever been without some sort of exercises of the body, which the defence of their persons, the preservation of health, and even recreation and mirth, would necessarily lead them to. See EXERCISES.

On the first establishment of society, men, being apprised of the necessity of military exercises, for repelling the insults of their neighbours, instituted GAMES, and proposed prizes, to animate their youth to combats of divers kinds. And as running, leaping, strength and dexterity of arm in throwing the javelin, driving a ball, or tossing a quoit, together with wrestling, &c. were exercises suited to the manner of fighting in those days, to the youth vied to excel in them, in the presence of the aged, who sat as their judges, and dispensed prizes to the conquerors; till what was originally only amusement, became, at length, a matter of such importance, as to interest famous cities, and entire nations, in its practice.

Hence arose an emulation and eagerness to excel, in hopes, one day, of being proclaimed and crowned conquerors in the public games, which was the highest honour a mortal could arrive at: nay, they went so far as to imagine, that even gods and demi-gods were not insensible of what men were so captivated with; and, in consequence hereof, to introduce the greater part of these exercises into their religious ceremonies, the worship of their gods, and the funeral honours done to the names of the dead.

Though it be hard to determine the precise epocha of the *gymnastic* art, yet it appears from several passages in Homer, and particularly the twenty-third book of the Iliad, where he describes the games celebrated at the funeral of Patroclus, that it was not unknown at the time of the Trojan war. From that desolation, which is the earliest monument now extant of the Grecian *gymnastics*,

it appears, that they had chariot-races, boxing, wrestling, foot-races, gladiators, throwing the discus, drawing the bow, and hurling the javelin; and it should seem, from the particular account Homer gives of these exercises, that even then the *gymnastic* art wanted little of perfection: so that when Galen says there was no *gymnastic* art in Homer's days, and that it began to appear no earlier than Plato, he is to be understood of the medicinal *gymnastics* only. This last, indeed, had its rise later; because, while men continued bold and laborious, they had no occasion for it; but when luxury and idleness had reduced them to the sad necessity of applying to physicians, these, who had found that nothing contributed so much to the preservation and re-establishment of health as exercises, proportioned to the different complexions, ages, and sexes, did not fail to refer them to the practice of *gymnastics*.

According to Plato, one Herodicus, prior a little time to Hippocrates, was the first who introduced this art into physic; and his success, convinced by experience of its usefulness, applied themselves in earnest to improve it.

Hippocrates, in his book of Regimen, has given instances of it, where he treats of exercise in general, and of the particular effects of walking, with regard to health; also of the different sorts of races, either on foot or horseback; leaping, wrestling, the exercise of the suspended ball, called *corymbus*, chironomy, unctious, frictions, rolling in the sand, &c.

But as physicians did not adopt all the exercises of the *gymnastic* art in their practice, it came divided between them and the masters of martial and athletic exercises, who kept schools, the number of which was greatly increased in Greece.

At length the Romans also caught the same taste; and, adopting the military and athletic exercises of the Greeks, they improved and advanced them to the utmost pitch of magnificence, not to say extravagance. But the declension of the empire involved the arts in its ruin, and, among others, *gymnastics* and medicine; which last unhappily then relinquished the title it had to the former, and has neglected to resume it ever since.

GYMNAIA, in *Zoology*, a new established class of animals, containing such as have neither tail, nor any visible limbs. See **ANIMATULA**.

GYMNIC, **GYMNICUS**, something belonging to the exercises of the body.

Gymnic games, *ludi gymnici*, are those wherein the body is exercised: such as wrestling, running, dancing, the use of the lance, quoit-playing, &c.

These made the chief diversions of the **OLYMPIC**, **NEAHEAN**, **PYTHIAN**, and **ISTHMIAN** solemnities; being called by the Greeks *Παιήλοιοι*, and the Latins *Quinquaginta*.

GYMNOCRITHON, in *Botany*, a name given by some authors to the *zephyrium*, or *teredum nudum*, the naked barley.

GYMNOPEEDIA, a kind of dance, established by Lycorgus, and in use among the ancient Lacedæmonians; performed, during their sacrifices, by young persons who danced naked, singing at the same time a hymn in honour to Apollo.

The word is also written *gymnopaedia*; it is compounded of *gymnos*, naked, and *paia*, child.

One Terpander is recorded as the inventor of the *gymnopaedia*. Athenæus describes it as a Bacchic dance, performed by youths stripped quite naked, with certain interrupted though agreeable motions and gestures of the body; the arms and legs being flourished and directed after a peculiar manner, representing a sort of real wrestling.

GYMNOPODIA, among the *Ancients*, a kind of shoes which discover the naked feet. They were worn by the Grecian women, who were very fond of them.

GYMNOPEYRIS, in *Natural History*, the name of a genus of fossils, the characters of which are these: they are of the class of the *pyrites*, and are compound, indissoluble, metallic bodies, found in detached masses, of no determinately angular figure; of a simple internal structure, not striated; and are naked, or not covered with any ineffectual coat or crust, in which they differ from the *pyrites*. See *Tab. of Fossils*, class 5.

Of this genus there are only two known species.

GYMNOSEPHISTS, a set of Indian philosophers, famous in antiquity; so denominated from their going barefoot. The word is formed of the Greek *γυμνός*, naked, q. d. a siphist or philosopher who goes naked.

This name was given to the Indian philosophers, whom the excessive heat of the country obliged to go naked; as that of *Peripatetics* was given to those who philosophized walking.

Laetius, Vives, &c. will not have *Gymnosophists* to have

been the name of any particular sect, but a common name of all the philosophers in the Indies; and hence they divide them into Brachmans and Germans.

Among the Germans, called also by Porphyry *Semantæ*, and by Clemens Alexand. *Semone*, some were called *Hyalistæ*, by Clemens Alexand. *Alabistæ*, as inhabiting the woods: which last seem to come nearest to the notion of *Gymnosophists*. Clemens relates, that these Alabistæ neither inhabit cities nor towns, are clothed mostly with the leaves of trees, eat acorns and berries, and drink water out of their hands, abstaining from marriage and procreation.

The *Gymnosophists* believed the immortality and transmigration of the soul: they placed the chief happiness of man in a contempt of the goods of fortune and the pleasures of sense, and gloried in having given faithful and disinterested counsels to princes and magistrates. It is said, that when they became old and infirm, they threw themselves into a pile of burning wood, in order to prevent the miseries of an advanced age. One of them, named Calamus, thus burnt himself in the presence of Alexander the Great.

Aristotle, *Florida* lib. ii. describes the *Gymnosophists* thus: "They are all devoted to the study of wisdom, both the elder masters and the younger pupils; and what to me appears the most amiable thing in their character is, that they have an aversion to idleness and indolence; accordingly, as soon as the table is spread, before a bit of victuals be brought, the youths are all called together from their several places and offices, and the masters examine them what good they have done since the last time: here one relates something he has discovered by meditation; another has learned something by demonstration; and as for those who have nothing to allege why they should dine, they are turned out to work till then."

The great leader of the *Gymnosophists*, according to Jerome, was one Buddas, called by Clemens Bara, who is ranked by Suidas among the Brachmans. That last author makes Buddas, the preceptor of Manes the Persian, the founder of the *Gymnosophists*.

There were likewise African *Gymnosophists*, who dwelt upon a mountain in Ethiopia, near the Nile, without the accommodation either of house or cell. These did not form themselves into societies, like those of India; but each had his private retirement, where he studied and performed his devotions by himself. If any person had killed another by chance, he applied to these sages for absolution, and submitted to whatever penances they enjoined. They pretended to an extraordinary frugality, and lived only upon the fruits of the earth. Lucian ascribes to these philosophers several new discoveries in astronomy.

GYMNOSPERMIA, in *Botany*, the name given by Linnaeus to a certain series of plants of the **DIDYMANIA** class. *Tab. II. Botany*, No. 11, and *Tab. V. class 14*.

GYMNOTUS, in *Icthyology*, the name of a genus of fishes, the characters of which are these: it is of the malacopterygious kind in the Artedean system, but in the Linnaean it belongs to the order of apodes; the branchiostegic membrane contains five bones, and it has no fin upon the back; the head is furnished with lateral covers; the upper lip with two tentacula; the eyes are covered with a skin; the body is flattened and carinated under the lower fin. Linnaeus enumerates five species of this genus, one of which is an American fish, described by Marcgrave under the name of *carapa*.

Another species is distinguished, on account of its electrical powers, by the name of the *gymnotus electricus*, or *electrical eel*, and by the French *anguille électrique*. This is a fresh-water fish found in the river of Surinam, in South America: the common size is from three to four feet in length, and from ten to fourteen inches in circumference about the thickest part of the body; however, it is said, that some have been seen in the river of Surinam which are upwards of twenty feet long, and whose stroke or shock proved instant death to those who received it. *Tab. II. Pishes*, No. 12.

This fish has been lately much the subject of examination. It is described, in general, by Mr. Bancroft, in his Essay on the Natural History of Guiana, and more minutely by Dr. Garden, in the Phil. Trans. The head is large and flat, and perforated with holes; the upper and lower jaws are of an equal length, and form a wide mouth without teeth; there are two nostrils on each side of the head, one pair being large and raised above the surface, the other small and level with the skin; the eyes are small, flat, and of a bluish colour; the body is thick and roundish near the head and to some distance from it, but gradually diminishes in size and increases in depth to the point of the tail, which is rather blunt; the back and sides are covered with many light-coloured spots; the

the whole body, from about four inches below the head, seems to be divided into four different longitudinal parts, viz. the upper part or back, which is roundish, and separated from the other parts by the lateral lines; these take their rise just above the pectoral fins, and gradually converge, as they run down along the sides towards the tail; the second part is the body of the fish, or its strong muscular part, separated from the former by the lateral lines; this is of a lighter blue colour than the back, and swells out a little on each side, but, toward the lower part, it is again contracted or sharpened into the *carina*, or keel, which is the third division; this part is thin and lax, and covered with a reticulated skin of a greyish colour; the *carina* begins about six or seven inches below the base of the head, and reaches down to the tail; it seems to be of a strong muscular nature, and terminates in a thin edge, on which is situated the fourth part or division, which is a long, deep, soft, wavy fin, continued from about three or four inches below the head to the end of the tail. The anus of this fish is placed underneath, and about an inch more forward than the pectoral fins; these are small, and circular in shape, and are placed, one on each side, just behind the head, over the *foramina spiratoria*, which are small, and generally covered with a lax skin, situated in the axillæ of these fins: the chief use of these fins seems to be to raise the head of the fish when he wants to breathe, which he does every four or five minutes, by raising his mouth out of the water: this circumstance shews that he is amphibious and has lungs; and Dr. Garden concludes, from his *foramina spiratoria*, that he has *branchiæ* likewise. The skin of the body is formed into a number of rugæ or angular bands, which reach across the body to the base of the *carina* on each side; thus it has a worm-like appearance, and, like the worm tribe, it has also a power of lengthening or shortening its body, and of swimming backwards or forwards. But the most astonishing property of this fish is its power, exerted at its own pleasure, of giving an electrical shock to any person, or number of persons joining hands, provided the first touched the fish, and the last put his hand into the water in which it swam. The shock is conveyed either by the immediate touch of the fish with the hand, or through the same metallic or other conductors which convey the electric fluid; and it is intercepted by the common non-conductors of that fluid. This shock has been sometimes strong enough to pass through a brass chain, if the links were not too numerous, and the chain tense. But in all experiments of this kind, it seems to have been necessary to form a proper communication between the different parts of the fish; though some persons have affirmed, that they were shocked by touching him only with one hand: in this case, however, some unobserved communication may have produced the effect. The surprising power which this fish possesses seems to have been designed for its defence and subsistence; the exercise of it in the latter view is observable, whenever small fishes, which are a part of its food (as well as worms and animal food in general) are thrown into the water: for these are first struck, till they are dead or stupefied, and afterwards swallowed. If one of these small fishes be taken out of the vessel where the *gymnotus* is, after it has been apparently killed, and put into fresh water, it will soon revive again. In some cases, the death, or apparent death of its prey, is not effected without several repeated shocks, which have been observed to increase in strength according to the occasion. These electrical qualities depend on particular organs, which have been dissected and accurately described by Mr. J. Hunter: of these organs there are two pairs, a larger and a smaller, placed on each side the fish, and separated from one another; and they constitute, perhaps, more than one third of the whole animal. The structure of the organs consists of flat partitions or septa, and cross divisions between them, by means of thin plates or membranes; of which transverse plates there are, in an inch of length, about 240, which multiply the surface in the whole to a vast extent. The nerves in this fish, which are appropriated for the exercise of its electrical powers, and which arise particularly from the medulla spinalis, whence they issue in pairs between all the vertebrae of the spine, and supply the organs, are much larger than those that are bestowed on any other part for the purposes of sensation and action. Mr. Hunter's anatomical description is illustrated by three plates. For a farther account of the electrical property of this fish, see TORPEDO. Phil. Trans. vol. lxx. part i. art. 10. p. 94. art. 11. p. 102, vol. lxx. part ii. art. 39. p. 395.

GYNÆCEUM, among the *Antients*, the apartment of the women; or a separate place, in the inner part of the house, where the women keep themselves retired, employed in their spinning, out of the sight of the men.

The word is compounded of the Greek *gynæ*, a woman, and *ceum*, a house.

Under the Roman emperors there was a particular establishment of *gynæceia*, being a kind of manufactories managed chiefly by women, for the making of cloaths, furniture, &c. for the emperor's household. Mention is made of these *gynæceia*, in the Theodosian and Justinian code, and by divers other authors.

In imitation hereof, divers of the modern manufactories, particularly those of silk, where a number of women and maids are associated and formed into a body, are called *gynæceia*.

GYNÆCIARIUS, a workman employed in the gymnasium.

In the ancient *gynæceia* these were men to weave and shape; the rest, as spinning, &c. being performed by women.

Criminals were sometimes condemned to serve in the *gynæceia*, much as now in the galleys; frequently, also, this was a kind of service which princes enacted of their subjects or vassals, both men and women, whom they made to work for them in their *gynæceia*.

GYNÆCOCOSMI, *Gynæcocratus*, in *Antiquity*, Athenian magistrates, whose business it was to regulate the women's apparel, according to the rules of modesty and decency. See **GYNÆCONOMUS**.

GYNÆCOCRATUMEN, an ancient people of Sarmatia Europæa, inhabiting the eastern banks of the river Tanais, near its opening into the Palus Mæotis; thus called, as authors relate, because they had no women among them; or, rather, because they were under the dominion of women.

The word is formed of *gynæ*, woman, and *cratumen*, vanquished, of *cratus*, I overcome, q. d. overcome by women.

Fa. Hardouin, in his notes on Pliny, says, they were thus called, because, after a battle which they lost against the Amazons on the banks of the Thermodon, they were obliged to have a venereal commerce with them, in order to get them children: *Et quod victoribus obsequium ad præcedendum eis fidebant*.

Hardouin calls them the husbands of the *AMAZONS*, *Amazones uxores*; for, as the author observes, the word *uxor* must be retrenched from Pliny, having been foisted into the text by people who were not masters of the author's meaning, *uxor*, *Amazones uxores*.

They who take the Amazons for a fabulous people, will conclude the fame of the *Gynæcocratumen*.

GYNÆCOCRACY, *GYNÆCOCRATIA*, a petticoat-government, or a state where women have, or may have, the supreme command.

The word is formed of *gynæ*, woman, and *cracy*, authority, power, government.

In this sense, England and Spain are *gynæcocracies*: the French value themselves, and think they are greatly happy, that their monarchy is not *gynæcocratic*.

GYNÆCOMASTOS, of *gynæ*, woman, and *mastus*, I bear, a term used by the ancients, to express a man whose breasts are large and turgid like those of women, and afford milk.

It was an observation among the ancients, that such men were naturally impotent. Paulus Ægineta observes, that the breasts of men as well as women swell at the time of puberty, but that those of women continue swelled, and those of men subside again, except in the case of the *gynæcomasti*, where they remain turgid, and become in time more and more so, as the fat increases under them.

As this swelling of the breasts gave a suspicion of impotency, those who laboured under that deformity, usually had recourse to a very painful operation in surgery to get rid of it. An incision was made in the form of a crescent in the lower part of the breast, then the skin being drawn back, the fat was taken out, and the lips of the wound healed by means of suture. When the breasts were very large and hung down, they made two incisions, one within the other, meeting at the extremities, and then separating all the skin between them, they took out the fat: and finally, if the disease returned, or they had performed the operation imperfectly, leaving some behind, they repeated the whole a second time.

GYNÆCONOMUS, the name of a magistrate of Athens, who had the custody and inspection of the women.

The word is compounded of the Greek *gynæ*, woman, and *nomus*, law.

There were ten *gynæconemi*; their business was to inform themselves of the lives and manners of the ladies of that city, and to punish such as misbehaved themselves, or transgressed the common bounds of modesty and decency.

They had a list hanging out, of the names of all those whom they had censured, or condemned to any mulct, forfeiture, penance, or other penalty.

GYNÆSIA, a word used by the writers in medicine, sometimes

times for the MENSTRUUM, and sometimes for the LOCHIA.

GYNANDRIA, in *Botany*, the twentieth class of plants in the Linnæan system, in which the male and female parts of the flower are joined at their origin, the stamens or male parts of which grow to the pistil or female part, and not to the receptacle of the seed. See **FRUCTIFICATION**, and *Tak of Botany*, class 20.

The word is formed of the Greek *gyn*, female, and *andria*, male.

The general character of this class of plants is very obvious: they are distinguished at first sight from all others, by the stamens being placed upon the style; or, in other words, the receptacle is elongated into the form of a style, and bears on it both the pistil and stamens. This class contains eight orders. *Tak. VI. Botany*, class 20.

The order of the *diandria*, the first of this class, is a very natural distinction among plants, and its genera differ from one another in no other respect particular but the stamens. Botanists, in general, have judged the roots of this order of plants, which are either reticulated or palmated, to be a very certain mark of distinction; but this distinction of the difference of the stamens, which is owing to Linnæus, is much to be preferred, as being both more certain and more obvious. The structure of the fructification in this order of plants is very singular: the germin of the pistil is always cotyledonate, and the petals are five in number; the two external ones often form themselves into a galea, the lower lip of which forms the nectarium, which supplies the place of a fifth petal and a pistil; the style is affixed to the interior margin of the nectarium, so that it and its stigma are scarce to be distinguished in the flower: the stamens are always two filaments, very short, and supporting two anthers, which are of a narrow shape below, and are naked and divided into several lobes, in the manner of the pulp of an orange; these are covered each with a small cell, which is open downwards, and growing on the inner margin of the nectarium: the fruit or seed-vessels is a capsule, containing only one cell, and formed of three valves; the seeds are very numerous, and as small as grains of dust, and are affixed to a slender receptacle, which is placed within each valve. This order comprehends nine genera; the *tribus*, *salicornia*, &c. the other orders are, the *triandria*, including four genera; *tetrandria*, containing one genus; *pentandria*, containing three genera; *hexandria*, containing two; *diandria*, containing two; *diandria*, including one genus; and *polyandria*, containing three genera.

The flowers of all the plants of this class have a strange, and, as it may be called, monstrous appearance, very different from that of all other plants in their flowers; but this is only owing to the singular disposition of the parts of fructification in these flowers, as described above. *Linnæi. Gen. Plant. p. 451.*

GYPSEUM, a name given by some writers to the *GYPSUM*, or fossil substance, of which the powder called *plaster of Paris* is made by calcination. There are in many parts of Arabia vast rocks of this stone; it resembles alabaster, but is softer, and of a more lax texture. It is found to be a very easy stone to form by tools, and therefore the Arabi build with it in some of the places in the neighbourhood of the quarries, but they are forced to make the walls very thick, as the stone is so soft and crumbly. The building called *Aristofa*, or *Aristofa Emir*, which seems the remains of a monastery, is built wholly of this stone; and when the sun shines upon it, the walls give such a lustre, that they dazzle the eyes; but the softness of the stone, and the redness of the mortar, have conspired to make it a very ruinous pile at present, though of no great antiquity, the stones having split and mouldered away in the walls, and the foundations failed in many places. *Phil. Trans. N° 218. p. 150.*

GYPSEUM METALLUM, in the *Natural History of the Ancients*, a name used for the common *lapis specularis*, of which they often made windows, as we do of glass. It was by some called *Cyprium metallum*, because frequently found in Cyprus.

GYPPOCHI, artists who work in plaster. See **PARADIGMATICA**.

GYPPOPHYLLA, in *Botany*, a genus of the *diandria digyna* class. Its characters are these: the flower hath a permanent bell-shaped empancens, cut into five parts at the top; it hath five oval stone pearls, and ten oval-shaped stamens; in the centre is situated a globular germin, which becomes a globular capsule with one cell, opening with five valves, filled with small roundish seeds. There are several species, which are plants of no great beauty.

GYPPOPHYTON, in *Botany*, a name given by some authors to the *fastigia antiquorum*, or fastige of the ancients.

GYPSON, in *Natural History*, the name of a class of

fossils, the characters of which are these: they are composed of small flat particles, irregularly arranged, and giving the whole masses something of the appearance of the softer marbles; they are bright, glossy, and in a small degree transparent; not flexible nor elastic, not giving fire with steel, nor fermenting with or dissoluble in acid menstrua, and calcine very easily in the fire.

Gypsum is found in very large quantities in many parts of the globe, forming extensive chains of mountains and hills, as in the neighbourhood of Paris. It is always crystallized or regularly disposed; but in its crystallization assumes a variety of forms. In some cases, it is composed of large, transparent, thin laminae, which are so applied to each other as to constitute masses as transparent as crystal: in this form it is called *lapis specularis*. In other cases, it is crystallized in *strata*, like threads applied longitudinally to each other: this is called *striated gypsum*. And sometimes a large quantity of *gypsum* is found in small irregular crystals, joined together, and forming considerable masses of semi-transparent granulated bones, commonly called *gypsum alabastrum*. We also meet with a tubercular *gypsaceous* stone, called also *selestinus*; and other *gypsums* are found, consisting of differently formed crystals, as hexagonal parallelepipeds and pyramids.

Gypsum is distinguished from calcareous earths by not dissolving and effervescing with acids; but M. Baume observes, that it may in some measure be dissolved by acids; however, in this case, it is separated by crystallization, without retaining any part of the acid: besides, quicklime does not harden, as *gypsum* does, without the addition of sand or cement. It has been observed by Mr. Pon, in his *Lithogegnesia*, that *gypsum* cannot be fused without addition by the most violent fire of furnaces; but Mr. D'Arcet has found that all *gypsaceous* stones and earths are fusible in this way by a violent and long-continued heat.

The author of the *Chemical Dictionary* infers, from the various properties of *gypsum*, that it is nothing else than calcareous earth saturated with vitriolic acid; or that it is a true *selestinus*. In want of hardness, its transparency, its crystallization, and its solubility in water, proceed from its saline character. It cannot be combined with any acid, because it is naturally saturated with the vitriolic acid. It requires much water to dissolve it, on account of its saline quality, or on account of the great quantity of earth which it contains, and the intimacy with which this earth is united with the vitriolic acid. Its calcination is nothing else than the sublimation of the water of its crystallization. The properties of quicklime, which it acquires by calcination, are owing either to the superabundant calcareous earth which it may contain, or rather to the sublimation of a part of the vitriolic acid, which is engaged during calcination, by touching some inflammable matter with which the acid unites and forms sulphur. And, finally, the hardening of plaster, when calcined and mixed with water, may proceed from a mixture of those parts, which, by calcination, have become quicklime, with other parts which have not required that quality, and which serve as a cement to the former; or it proceeds from the *gypsum* refusing the water of its crystallization, and again crystallizing precipitately and confusedly. *Art. Gypsum.*

All the species burn with a very slight degree of fire, so that which is commonly called *plaster of Paris*; but the softer require the smaller degrees of fire, and in general, the harder and more marbly make the better plaster. The common way of burning this stone into plaster, is too slight to give it all the hardness it is capable of. It is reported by many, that a greater degree of heat renders it much superior in hardness; and it is said, that the artificial marble, with which the whole palace of Munich is adorned, and which the elector of Bavaria esteems more than marble, for which it is mistaken by all that see it, is made of the common *gypsum*, first burnt in the ordinary way, and afterwards put over the fire again in a copper vessel, and suffered to boil, as it will like water, for a long time: when this boiling ceases of itself, the matter is taken out, and common colours, such as are used in painting, are mixed with it in various proportions; which, on the wetting it with water, and working it in the common manner of plaster of Paris, diffuse themselves, and imitate the veins of natural marble. *Phil. Trans. N° 91.*

The method of preparing it will be shown under the article *MOZAIC*.

Gypsum is used in the Canaries by way of remedy for their wine; and about Malaga a large quantity is consumed up with the juice of their grapes.

Gypsum striatum, *striated plaster-stone*, in *Natural History*, the name commonly used for the whitish less glossy *selestinus*, with short thick filaments.

It is of a rude, irregular, and unequal surface, and is, in

GYR

friable texture, found in masses of various sizes, from one to twelve or eighteen inches over, but always broad and flat, its thickness being usually but an inch and a half, and in the broadest pieces seldom much more than two inches: it is composed of considerably large and coarse longitudinal filaments, running usually very evenly through the mass: it is easily fissile in a perpendicular direction, that is parallel to the arrangement of these filaments: it is of a dull whitish colour, and its filaments, when examined singly, have a slight share of transparency. It will not at all give fire with steel, or ferment with aqua fortis, but very readily calcines to a perfectly white substance. It is found in clay and marl-pits, among the strata of gravel, and in the fissures of stone, and is common in Yorkshire and other parts of the kingdom. The Germans use it in fluxing the sulphureous ores of metals; and our druggists sell it under the name of English talc, for cleansing of silver lace.

GYPSUM *symplicum* is a name given by the ancients to the white chalk, which was esteemed by them for the cleansing of cloths, and which makes an excellent plaister or cement without previous burning. See *CALX nativa*.

GYPSY, a name given to a set of vagrants. See *EGYPTIANS*.

GYRFALCON, in *Ornithology*, the name of a large and fierce species of *FALCON*, called in English the *jerfalcon*. Its name is a compound of the German *gyr*, which sig-

GYR

nifies a *cultur*, and *falso*, the *falcon*. It is the largest of all the falcon kind; its head is flatted, and of a greyish colour; the throat is of a pure white; its beak very thick and strong, but short, and of a bluish colour; the breast and belly are marked with narrow lines, thinly scattered, and pointing down; the wings with large heart-shaped spots; the middle feathers of the tail with a few bars; the legs are thick and strong, and feathered a little below the knees, and both they and the feet are of a pale blue.

It is a very bold and daring bird, attacking all other fowl without reserve, and particularly the heron and stork kind: the other falcons are all afraid of this. It is sometimes quite white, and was formerly in high esteem when falconry was in vogue.

GYRINUS, in *Zoology*, a name used for a species of the *MORDELLA*.

GYRLE, among *Sportsmen*. See *GIRLE*.

GYROMANCY, *GYROMANTIA*, a kind of *DIVINATION*, performed by walking round, or in a circle.

The word is compounded of the Greek *gyros*, *circle*, and *mantia*, *divination*.

GYROVAGI, in *Ecclesiastical Writers*, monks, who leaving their monasteries, under pretence of piety, wandered about from one religious house to another.

The same appellation was also given to priests who left their parishes.

H.

H, Is the eighth letter of our alphabet, and the sixth consonant.

Varro, De Re Rustica, lib. iii. cap. 1. calls the *h*, *afflatus*; and Marianus Capella says, it is pronounced by only a gentle contraction of the trachea. Hence it has been disputed, whether or no the *h* be a real letter.

Some will only have it to be an aspiration, or spirit, because its sound is so weak. And accordingly the Greeks, of later ages at least, do not place it in the line with the other letters, but put it over the head of the letter which follows it; though it should seem they anciently wrote it in the same line with the rest.

The Latin grammarians, as they were religious imitators of the Greeks, have, on their authority, generally disallowed the *h* as a letter; and the moderns have here followed the Latins, urging, that it is founded only by a strong emission of the breath, without any conformation of the organs of speech, and therefore that it is no letter. However, others maintain that the *h*, like all other aspirates, from the time it is aspirated, and for this very reason that it is aspirated, is not only a letter, but a real consonant; it being a motion, or effort of the larynx, to modify the sound of the vowel that follows; as is evident in the words *hæc*, *hæd*, *hæc*, &c. where the vowel *e* is differently modified from what it is in the words *cedere*, *ratum*, *clid*, &c. and such modification is all that is essential to a consonant. They add, that the *h* is either a letter, or *f* and *m* are none; those being no more than hissing aspirations; and that they who exclude the *h* from among the letters, as conceiving it only a mark of aspiration, might as well exclude the labial consonants *b* and *p*, and say they are only marks of certain motions of the lips, &c. Hence they conclude that the *h* is a letter, and a consonant of the guttural kind, i. e. a consonant, to the pronunciation whereof the throat concurs, in a particular manner, more than in any other of the organs of voice.

It is true, in many words beginning with *h*, the aspiration is very weak, and almost insensible; the *h* in those cases not doing its office; but it does not cease to be a consonant on that score, more than the various other consonants, which we write but do not pronounce; as the *k* in *quid*, &c. and several other letters, particularly in the Hebrew, French, &c. Nor does it cease to be a consonant, because it does not hinder the elision of the foregoing vowel, when another vowel follows in the subsequent word; for then *m* would undergo the same disqualification.

M. Menage distinguishes two kinds of *h*; the one an aspirate, which he allows a consonant, the other a mute, which he considers as a vowel. Now, it is certain, the aspirated *h* is a consonant; but the mute *h* is no vowel, as having no peculiar or proper sound distinct from that of the vowel, or diphthong, immediately following it.

When the *h* is preceded by a *c*, the two letters together have frequently the sound of the Hebrew *ch*, with a point over the right horn; as in *charity*, &c.

In most words derived from the Greek, and beginning in that language with the letter *χ*, the *ch*, which begins them in English, has generally the sound of a *c*, as in *cho*, *charis*, &c. though it is sometimes softened a little, as in *Cherubim*, &c.

After a *p*, the *h* is always pronounced together with the *p*, like an *f*, as in *phagesis*, *Philistines*, *phlegm*, *phibetom*, *philosophy*, *Phazemon*, &c. Most words of this class are either proper names, or terms of art, borrowed from the Greek, or the Oriental languages; and written in Greek with a *p*, and with a *h* in the others.

The *h* in English is scarcely ever mute at the beginning of a word, or where it immediately precedes a vowel,

as *houst*, *habitation*, &c. Where it is followed by a consonant, it has no sound, according to the present pronunciation.

In ancient authors we frequently meet with *h* put instead of *f*, as *hæc*, for *fac*; but this is principally observable in the Spanish tongue, where most of the words borrowed from the Latin beginning with an *f*, take the *h* in lieu of it: as *hæter*, for *fabulari*; *hæc*, for *fac*; *hæd*, for *facum*. For the relation which *h* has to the Æolic digamma, see the letter *F*.

The aspirate or sharp accent of the Greeks, which is the same with our *h*, is also frequently changed in the Latin for an *s*; as *hæc*, *sal*; *hæc*, *sepem*; *hæc*, *ser*; *hæc*, *serp*; *hæc*, *semis*; *hæc*, *ser*, &c. The *h* is also used for some other letters, enumerated at large by Passerat, De Literarum inter se Cognatione & Permutatione.

Anciently the *h* was put for *ch*; thus *Chideceus* was formed *Hudeceus*, as it is read on all the coins of the sixth and seventh centuries; and it was on this account, that they wrote *Hudeceus* with an *h*. In course of time, the sound of the *h* being much weakened, or entirely suppressed, the *h* was dropped, and the word was written *Ludeceus*. In like manner we read *Histaira*, *Hlevis*, &c. F. Lobineau will have this difference to have arisen from the differences in the pronunciation. Such, says he, as could not pronounce the guttural, wherewith these words begin, substituted a *c* for it; and they who pronounced it so, wrote it after the same manner; but such as were accustomed to pronounce the guttural, wrote it likewise. He might have added, that such as could not pronounce it, at length absolutely rejected it, and both wrote and spoke *Ludeceus*, *Lustaira*, &c. Some learned men have conjectured that the *h* should have been detached from the name; and that it signified lord, from the Latin *hæc*, or the German *hæc*. Much as the *D*, which the Spaniards prefix to their proper names, as *D. Philip*, for Don Philip. But as it is likewise found before the names of several cities, it is more probable the letter was there used to denote the rough, harsh pronunciation of the ancient Franks.

In reality, the most ancient way of writing the names of these French kings, was not by *h*, but by *ch*; where the *c* seems to have stood for *king*, *king*, and the *h* was inserted to give the *c* a guttural sound.

The *h* is sometimes also found prefixed to the *c*; as *Hæc*, *hæc*, *hæc*, &c. See *Cavalas*, *colende*, &c.

H, among the *Anglicani*, was also a numeral letter, signifying 200, according to the verse:

Hæcque ducentis per se designat habendus.

When a dash is drawn at the top of the *H*, it signified two hundred thousand. See what has been observed on this subject under the letter *A*.

HABAKKUK, one of the twelve lesser prophets, whose prophecies are taken into the canon of the Old Testament.

The name is written in Hebrew with *חבכ* and signifies a *weaver*, or *weaver*. The Greek translators call him *Habakum*.

The precise time is not known when *Habakkuk* prophesied; but from his predicting the ruin of the Jews by the Chaldeans, it may be concluded that he was contemporary with Jeremiah, and prophesied in the reign of Josiah. His prophecy only consists of three chapters.

HABDALA, or *HABDILAH*, a Jewish ceremony, practised among that people every Sabbath day evening.

The word is Hebrew, and literally signifies *separation*: it is formed of *חבדל*, *hædæl*, to separate; the ceremony being looked upon as the division or parting of the Sabbath from the rest of the week. It was established to prevent their being too hasty in ending the Sabbath.

Towards,

Towards the close of the Sabbath, when the stars begin to appear, every master of a family lights a torch or flambeau, or at least a lamp with two wicks. A little box of spices is then prepared, and a glass of wine taken; then singing or rehearsing a prayer, and blessing the wine and the spices, they all smell at them; and, after a few ceremonies performed about the torch, or lamp, they cast a little of the consecrated wine into the flame; every body tastes; and thus they break up, wishing each other, not a good night, but a good week.

HABEAS corpus juratum, is a writ that lies for bringing in a jury, or to many of them as refuse to come upon the *venue facias*, for the trial of a cause brought to issue. This is of the same nature in the common pleas, as the *DISTINGAS juratura* in the court of king's bench.

HABEAS corpus, in *Law*, a writ, which a man indicted and imprisoned for any crime, or trespass, before the justices of peace, or in a court of franchise; having offered sufficient bail, which is refused, though the case be bailable; may have out of the king's bench, thereby to remove himself thither, at his own costs, to answer the cause at the bar thereof.

The order, in this case, is first to procure a *certiorari* out of the chancery, directed to the said justices, for removing the indictment into the king's bench; and upon that to procure this writ to the sheriff, for causing his body to be brought at a certain day.

This writ is also used to bring the body of a person into court, who is committed to any goal, either in criminal or civil causes; and a *habeas corpus* will remove a person and cause from one court and prison to another. Of this there are various kinds: such is the *habeas corpus ad respondendum*, when a man hath a cause of action against one who is confined by the process of some inferior court; in order to remove the prisoner, and charge him with this new action in the courts above: such is that *ad satisfaciendum*, when a prisoner hath had judgment against him in an action, and the plaintiff is desirous to bring him up to some superior court to charge him with process of execution. Such also are those *ad prefigendum*, *reficiendum*, *deliberandum*, &c. which issue when it is necessary to remove a prisoner, in order to prosecute or bear testimony in any court, or to be tried in the proper jurisdiction wherein the fact was committed. Such is, likewise, the common writ *ad faciendum et recipiendum*, which issues out of any of the courts of Westminster-hall, when a person is sued in some inferior jurisdiction, and is desirous to remove the action into the superior court; commanding the inferior judges to produce the body of the defendant, together with the day and cause of his caption and detention, whence the writ is frequently denominated *ad habeas corpus cum causa, de deo et pectore* whatsoever the king's court shall command in that behalf. This is a writ grantable of common right, without any motion in court; and it instantly supersedes all proceedings in the court below. But the great and efficacious writ in all manner of illegal confinement is that of *habeas corpus ad liberandum*, directed to the person detaining another, and commanding him to produce the body of the prisoner, with the day and cause of his caption and detention, to do, submit to, or receive the award of the judge or court. This is a high prerogative writ, issuing by the common law out of the court of king's bench, not only in term-time, but also during the vacation, by a writ from the chief justice, or any other of the judges, and running into all parts of the king's dominions. In this court it is necessary to apply for this writ by motion to the court, as of *certiorari*, prohibition, mandamus, &c. shewing some probable cause, why the extraordinary power of the crown is called in to the party's assistance; and when a probable ground is shewn, that the party is imprisoned without just cause, the writ of *habeas corpus* is then a writ of right, which may not be denied, but ought to be granted to every man that is committed to prison, or detained there, or otherwise restrained, though it be by the command of the king, the privy-council, or any other.

The writ of *habeas corpus* was originally ordained by the common law of the land, as a remedy for such as were unjustly imprisoned, to procure their liberty; but many abuses having been introduced into the mode of granting it, it became necessary to prevent them by modern statutes. Accordingly, by the petition of right, 3 Car. I. it is enacted, that no freeman shall be imprisoned or detained, without cause shewn, to which he may make answer according to law. And by 16 Car. I. cap. 10. if any person be restrained of his liberty by order or decree of any illegal court, or by command of the king's majesty in person, or by warrant of the council board, or of any of the privy-council, he shall, upon demand of his counsel, have a writ of *habeas corpus*, to bring his

body before the court of king's bench or common pleas; who shall determine whether the cause of his commitment be just, and thereupon do as to justice shall appear. The methods of obtaining this are further pointed out and enforced by 31 Car. II. cap. 2. See the next article.

HABEAS corpus est is the famous statute 31 Car. II. cap. 2. which some have called the *second Magna Charta*, and bulwark of English liberty. The substance of this important statute is comprised in the following particulars; viz. 1. That the writ of *habeas corpus* shall be returned, and the prisoners brought up within a limited time according to the distance, not exceeding in any case twenty days. 2. That such writs shall be subscinded as granted in pursuance of this act, and signed by the person awarding them. 3. That on complaint and request in writing by or on behalf of any person committed and charged with any crime (unless committed for treason or felony, expressed in the warrant, or for suspicion of the same, or as accessory thereto before the fact, or convicted or charged in execution by legal process) the lord chancellor, or any of the twelve judges, in vacation, upon viewing a copy of the warrant or affidavit, that a copy is demanded, shall (unless the party has neglected for two terms to apply to any court for his enlargement) award a *habeas corpus* for such prisoner, returnable immediately before himself, or any other of the judges; and upon the return made shall discharge the party, if bailable, upon giving security to appear and answer to the accusation in the proper court of judicature. 4. That officers and keepers neglecting to make due returns, or not delivering to the prisoner or his agent within six hours after demand a copy of the warrant of commitment, or shifting the custody of a prisoner from one to another, without sufficient reason authority (specified in the act) shall for the first offence forfeit 100*l.* and for the second offence 200*l.* to the party grieved, and be disabled to hold his office. 5. That no person, once delivered by *habeas corpus*, shall be recommitted for the same offence, on penalty of 500*l.* 6. That every person committed for treason or felony shall, if he requires it, the first week of the next term, or the first day of the next festival of oyer and terminer, be indicted in that term or session, or else admitted to bail; unless the king's witnesses cannot be produced at that time; and if acquitted, or if not indicted and tried in the second term or session, he shall be discharged from his imprisonment for such imputed offence; but that no person, after the assize shall be opened for the county, in which he is detained, shall be removed by *habeas corpus*, till after the assizes are ended; but shall be sent to the justice of the judges of assize. 7. That any such prisoner may move for and obtain his *habeas corpus*, as well out of the chancery or exchequer, as out of the king's bench or common pleas; and the lord chancellor or judges denying the same, on sight of the warrant or oath that the same is refused, forfeit severally to the party grieved the sum of 500*l.* 8. That this writ of *habeas corpus* shall run into the counties palatine, cinque ports, and other privileged places, and the islands of Jersey and Guernsey. 9. That no inhabitant of England (except persons contracting, or convicted praying to be transported, or having committed some capital offence in the place to which they are sent) shall be sent prisoner to Scotland, Ireland, Jersey, Guernsey, or any places beyond the seas, within or without the king's dominions; on pain that the party committing, his advisers, aiders, and assistants, shall forfeit to the party grieved a sum not less than 500*l.* to be recovered with treble costs; shall be disabled to bear any office of trust or profit; shall incur the penalties of *praemunire*, and shall be incapable of the king's pardon. And, lest this act should be evaded, by demanding unreasonable bail, or sureties, for the prisoner's appearance, it is declared by 1 W. & M. stat. 2. cap. 2. that excessive bail ought not to be required.

In consequence of this act, it is now expected by the court, that upon writs of *habeas corpus* at the common law, the writ should be immediately obeyed, without waiting for any *alias* or *pluries*; otherwise an attachment will issue. Blackst. Comm. vol. III. p. 126, &c.

HABENA, in *Surgery*, the name of a BANDAGE contrived to keep the lips of a wound together, and save the painful operation of a *SUTURE*.

HABENDUM, in *Law*, a word of course in a conveyance. In every conveyance are two principal parts, the *premises*, and the *habendum*: the office of the first is to express the name of the grantor, the grantee, and the thing granted.

The *habendum* is to limit the estate, so that the general implication, which, by construction of law, passed in the premises, is by the *habendum* controuled and qualified.

Thus in a lease of two persons, the *habendum* to one for life,

life, shews the general implication of the joint tenancy in freehold, which should pass by the premises, if the *habentem* were not.

HABENTIA, in *Law*, signifies riches. In some ancient charters, *habentia* begins is taken for rich men; and we read, *non esse solum solum requirit, vel habentes homines, cum eis domibus habitantibus*.

HABERDASHER, in *Commerce*, a seller of hats, and other small wares.

The master and warden of the company of *haberdashers* in London, calling to their assistance one of the company of coppers, and another of the hat-makers, and mayors, &c. of towns, may search the wares of all hat-makers who work here with foreign wool, and who have not been apprenticed to the trade, or who dye them with any thing but copperas and galls, or woad and madder; in which cases they are liable to penalties by stat. 8 Eliz. cap. 7. and 1 Geo. II. cap. 23.

For the etymology of this denomination, see **BERDASH**.

HABERDASHERS' hospital. See **HOSPITAL**.

HABERE facias possessionem is a writ that lies where one has recovered a term for years in an action of ejectment, in order to put him into possession again.

HABERE facias seisinam, a judicial writ, which lies where a man has recovered lands in the king's court directed to the sheriff, commanding him to give him the seisin thereof.

This writ sometimes also issues out of the records of a fine, directed to the sheriff of the county where the lands lie; commanding him to give to the cognizee, or to his heirs, seisin of the land where the fine is levied.

In the execution of these writs, the sheriff may take with him the posse comitatus, and may justly breaking open doors, if the possessor be not quietly furnished. But if he be peaceably yielded, the delivery of a twig, a turf, or the ring of the door, in the name of seisin, is sufficient execution of the writ.

There is also a writ called **HABERE facias seisinam, ubi res habuit animum, deum, &c.** which lies for the delivery of lands to the lord of the fee, after the king had taken his due of a person's lands, who was convicted of felony.

HABERE facias eisen is a writ that lies in divers cases, as in dower, formidone, &c. where a view is to be taken of the land or tenement in question.

HABERGION, or **HABERGION**, **HABERGION**, a coat of mail; an ancient piece of defensive armour, in form of a coat, descending from the neck to the middle; and formed of little iron rings, or masses, linked into each other.

The word is also written *haberge, haberge, haberge, haberge, haberge, haberge, haberge*. Spelman takes it to have been formed from the ancient French *habili, habili, habili, habili, habili, habili, habili*, as serving to defend the upper part of the body. Du-Cange and Skinner choose to derive it from the Belgic *habili*, or Teutonic *habili*, neck, and *habili*, to wear, as if it were a peculiar defence for the neck. Others will have it formed of *ah, alla, q. d. ali, and haberge*, as cover; as importing it a cover for the whole body.

HABHAZZIA, in *Botany*, a name given by Leo Africanus, and some other of the writers of geography, to a plant growing in many parts of Africa, which they say produces its fruit under the earth in form of small round globules, which are much esteemed as food, and have the taste of an almond. The fruit, as it is called, is no other than the distinct tubers of the root, which are connected by fibres or strings, and are in the propagation of the plant very useful to its spreading over a large space of ground in a little time; all the fibres which shoot out horizontally from the root being terminated by these tubers, and each of these sending out on the opposite side several other fibres, which at due distances produce other tubers. The Africans dig up the ground at random near to the place where they see any of these plants, and never fail of picking up a great number of them. The plant which produces them is the *TARSI*, and they are eaten in many other places besides Africa. The Spaniards are very fond of them, and call them *AVELLANDA*, from their likeness to hazel-nuts in shape.

HABILIMENTA, in *Law*, in our *Ancient Statutes*, signify armour, harness, armour, or other provisions for war; without which there is supposed no ability to maintain war.

HABIT, in *Philosophy*, an attitude, or disposition, either of mind or body, acquired by a frequent repetition of the same act.

Some of the schoolmen call this a *qualitative habit*, and define it a quality adventitious to a thing, fitting and disposing it either to act or suffer.

Others define *habit* an affection of mind or body, persisting by long use and continuance. In which sense *eloquence*, a

constant *habit*, is distinguished from *habitus*, a present disposition, liable soon to alter.

HABIT may be distinguished into three of the mind, and of the body. This virtue is called a *habit* of the mind; strength, a *habit* of the body.

All natural *habits*, whether of body or mind, are no other than the body and mind themselves, conformed as either acting or suffering; or they are modes of the body or mind, wherein either perfectures, or are affected by some contrary mode. Aristotle enumerates five *habits* of the mind; viz. understanding, knowledge, wisdom, prudence, and art; which divide the later writers into three, and only admit of three intellectual *habits*; viz. science, prudence, and art; agreeable to the three kinds of objects, about which the mind has occasion to be facilitated; which are either theoretical, practical, or elective.

Virtues and vices are considered by philosophers under the notion of good and bad *habits*.

The archbishop of Cambray denotes *habits*, in general, to be certain impressions left in the mind; by means whereof, we find a greater ease, readiness, and inclination, to do any thing formerly done, by having the idea ready at hand to direct us how it was done before. Thus, e. g. we form a *habit* of sobriety, by having always before us the inconveniences of excess; the reflections whereof, being often repeated, render the exercise of that virtue continually more and more easy.

F. Malebranche gives a more mechanical theory of the *habits*. His principle is, that they consist in a facility which the spirits have acquired, of passing easily from one part of the body to another. He argues thus: If the mind act on, and move the body, it is, in all probability, by means of a flock of animal spirits lodged in the brain, ready to be sent at the motion of the will, by means of the nerves, which open or terminate in the brain, into the muscles of the body.

Now, an influx of spirits into a muscle, occasions a swelling, and, of course, a shortening of the muscle; and, consequently, a motion of the part to which that muscle is fastened.

Farther, the spirits do not always find all the roads open and free, which they are to pass through; whence that difficulty we perceive of moving the fingers, with that quickness necessary to play on a musical instrument; or of moving the muscles necessary to pronounce the words of a foreign language. But, by degrees, the spirits, by their continual flux, smooth the ways; so that at length they meet with no resistance at all. In this facility the spirits find of passing, when directed into the members of the body, *habits* consist.

On this hypothesis, it is easy to account for an infinity of phenomena relating to the *habits*. Why, for instance, children acquire new *habits* with more ease than grown persons? Why it is difficult to get rid of inveterate *habits*? Wherein that incredible quickness in the pronunciation of words, even without thinking of them; as is particularly observable in those long accustomed to formulas, &c.

On this footing, the faculty of memory appears to have very much the nature of a *habit*, inasmuch that in one sense it may pass for a *habit*.

Custom, says Mr. Locke, settles *habits* of thinking in the understanding, as well as of determining in the will, and of motions in the body; all which seem to be but trains of motion in the animal spirits, which, once a group, continue in the same way they have been used to, which by often treading are worn into a smooth path; and the motion in it becomes easy, and as it were natural. Essay on the Human Understanding, book II. ch. 33. See **ASSOCIATION** of Ideas.

HABIT, in *Medicine*, is what we otherwise call the temperament or constitution of the body; whether obtained by birth, or occasioned by the manner of living.

An ill, disordered *habit*, without any particular apparent disease, the physicians usually call a *cachexia*, or *cachymia*.

A thing is said to enter the *habit*, when it becomes intimately diffused throughout the body, and is conveyed to the remotest fibres of circulation.

HABIT is also used for a dress, or garb; or the composition of garments where with a person is clothed.

In this sense we say, the *habit* of an ecclesiastic; of a religious, &c. the military *habit*, &c.

The ecclesiastical *habit* only commenced about the time of Gregory the Great, i. e. it only began at that time to be distinguished from the lay *habit*; viz. in the sixth century. The establishment of the barbarous nations was the occasion thereof; for the laymen took the *habit* of the nations they had submitted to, but the priests kept to the Roman dress.

The abbot Baillet has an exact treatise on the ecclesiastical *habit*; wherein he maintains, contrary to the common

common opinion and custom, that the ecclesiastical *habit* should be a short one, and that a short *habit* is more decent than a long one.

The different *habits* and clanks which the generality of the world wear, are through inadvertency and imitation very frequently the cause of very unhappy maladies. Mr. Winslow, in the *Memoirs of the Royal Academy of Sciences at Paris*, has observed, that the greatest attention and care are necessary on several occasions in regard to this, as it is supposed, trifling article; and given many instances of the ill effects of it. The ancients have observed the inconveniences of many parts of dress, and daily observation confirms to us the many mischiefs the ladies suffer from the stiff whale-bone stays they wear, and the disorders of the viscera of the lower body, to which those are subject who lace themselves too tightly; and this is not only of dangerous consequence to themselves, but frequently is the death of children in breeding women.

The tight binding of the neck by the men's neckcloths, stocks, or the too tight collars of their shirts, &c. has been very frequently the only occasion of several very terrible disorders of the head, the eyes, and the breast; deafness, vertiges, faintings, and bleedings at the nose, are the frequent consequences of this practice; and the physicians consulted for relief in these cases, have found all means ineffectual, merely from their not attending to the cause of the malady; when a cure might have been, and often has been, made without the help of medicines, only by leaving off those unnatural bandages which had been the occasion of them, from the not suffering the free return of the blood by the regular veins, which had pressed up into the head, without mollescence, by the constricted arteries.

Mr. Cruget added to these relations, that a certain officer in the army of the king of Denmark, always ordered his soldiers to tie their cravats very tight, and garter their stockings below the knees, tying them also very hard; by which means they always looked red and swelled in the face, and thick legend, so that his men always appeared stout, robust, well fed, and in good case. But the consequence of this was, that after some time his men were all seized in a very particular manner with disorders, for which the common methods of treatment gave no relief, and great numbers of them died, after all the internal as well as external methods which could be tried, were found ineffectual. Their disease seemed a kind of scorbutic infection; and this not only appeared externally, but was found to affect even the internal parts of such of them as were opened after their death. It is unquestionable, that this wholly proceeded from the ligatures they continually wore about their necks and legs by order of their officers, and might have been cured merely by leaving them off; and it has even been proved on animals, as calves, sheep, &c. that extremely tight ligatures on their legs, &c. will have so great an effect, as to alter the whole mass of blood, render the animal moribund, and even make the flesh unwholesome and unfit for food. *Memoirs Acad. Scien. Par. 1740.*

Mr. Winslow has observed, that the different motions of the bones of the foot, which are very free in their natural state as is very plainly seen in young children, are usually wholly lost to us as we grow up, by means of the improper pressure of our shoes. The high-heeled shoes the women wear, entirely change the natural conformation of the bones of the whole foot. They render the foot elevated and arched, and incapable of being flattened, on account of the unnatural union and ankylosis they bring on between the bones, which is not unlike that which happens to the vertebrae of people who are hump-backed; for these high shoes make the extremity of the os calcis, to which the tendo Achillis is affixed, to be always unnaturally elevated, and the anterior part of the foot on the contrary is much more depressed than it naturally would be. The consequence of this is, that the muscles which cover the hinder part of the leg, which serve by the attachment of the tendon to stretch out the foot, are continually in an unnatural state of contraction; while the muscles of the anterior part of the leg, whose office is to bend the foot forward, are on the contrary kept in a like unnatural state of elongation and distention. To this cause it is owing, that we very frequently see women unable to go down a hill, or any declivity, without great pain; whereas, on the contrary, in walking up a hill, their high-heeled shoes make them walk as it were, not even ground; the end of the foot being only so far elevated as to bring it on a level with the unnatural position of the heel. The women who wear this sort of shoes find it also very troublesome to walk for a long time, though it be on the most even ground, and especially if they are obliged to walk quick. They can by no means leap so freely and easily as those

who wear lower heeled shoes. The reason of which is, that in the human species, as well as in birds and beasts, the action of leaping is executed by a sudden lifting up the hinder part of the os calcis, by means of the action of those muscles to which the great tendon is affixed. Low-heeled shoes by no means favour the ease to any of these inconveniences, but, on the contrary, they greatly facilitate all the natural motions of the feet, as we have daily innumerable instances in the labourers, chairmen, porters, and others of the lower class of mankind; and the wooden shoes worn by the lower class of people in France, notwithstanding their weight and inflexibility, do not so much prevent the proper motions of the muscles, whose office it is to move the feet. For beside the toughness of their heel, they are rounded at the end downwards, which in some degree compensates for their inflexibility, serving in the place of the alternate inflection of the foot on its toes on the one part, while the other is lifted up in walking.

But to return to the mischiefs done by high-heeled shoes, there is yet a further inconvenience from them than what has been mentioned, since not only the muscles of the tendo Achillis, which serve to move the foot in the extension, but the anterior muscles also, which serve to the extension of the toes, are by the height of these shoes always in an unnatural state; and not only the anterior muscles, which serve to the bending of the foot, but the posterior muscles also, which serve to the bending the toes, are, at the same time, by means of this height, kept forcibly in an elongated and extended state. This continual unnatural shortening of some of the muscles, and as unnatural lengthening of others, cannot but cause, sooner or later, a greater or lesser distemperature of their vessels, as well the veins and arteries as the lymphatics and nerves; nor may this be confined merely to the parts affected, but by the communication of these vessels with those of other more distant parts, may, even with these of the abdomen and its viscera, may bring on disorders which will be attributed to very different causes, and therefore will be treated with medicines which will not only prove useless, but in many cases hurtful. It is certain that long custom makes these unnatural extensions and contractions of the muscles as it were natural to women; inasmuch that those who are accustomed to these shoes would find it painful and disagreeable to walk in others. But this is no proof that the unnatural state in which the muscles are continually kept, may not often be the occasion of all the remote disorders before limited at, and which, many of them at least, may appear to have no relation to their original cause. *Memoirs de Acad. Scien. Par. 1740.*

HABIT is particularly used for the uniform garments of the religious, conformable to the rule and order whereof they make profession: as the *habit* of St. Benedict, of St. Augustine, &c.

In this sense we say absolutely, such a person has taken the *habit*; meaning, he has entered upon a NOVITIATE in a certain order. So he is said to quit the *habit*, when he renounces the order. See VOVE.

The *habit* of the several religious are not supposed to have been calculated for singularity or novelty: the founders of the orders, who were at first chief inhabitants of deserts and solitudes, gave their monks the *habit* usual among the country people. Accordingly, the primitive *habit* of St. Anthony, St. Hilary, St. Benedict, &c. are described by the ancient writers, as consisting chiefly of sheep-skins, the common dress of the peasants, shepherds, and mountaineers, of that time; and the same they gave to their disciples.

The orders established in and about cities and inhabited places, took the *habit* worn by other ecclesiastics at the time of their institution. Thus, St. Dominic gave his disciples the *habit* of regular canons, which he himself had always worn to that time. And the like may be said of the Jesuits, Barnabites, Theatines, Oratorians, &c. who took the common *habit* of the ecclesiastics at the time of their foundation. And what makes them differ so much from each other as well as from the ecclesiastical *habit* of the prelate times, is, that they have always kept invariably to the same form; whereas the ecclesiastics and laics have been changing their mode on every occasion.

HABITATION, a dwelling-place, or HOUSE.

HABITATION is sometimes also used for COHABITATION.

HABITUAL, some times that is become a habit, or habitude.

Thus we say, an *habitual* or inveterate disease; *habitual* sin, &c.

HABITUAL GRACE. See GRACE.

The Romish divine holds *habitual grace* only necessary in order to be saved; and actual *grace* to the doing any thing meritorious.

HABITUDE, *HABITUDO*, in the *Schools*, signifies, the respect or relation which one thing bears to another.

In this sense *habitus* is one of Aristotle's categories. Some of the *virtutes* specific and accurate *philosophi* consider *habitus*, as a genus; and subdivide it into two species. Where it is considered as a *quiescent*, they call it *habitus*; where as *in act*, *relativus*; to which some add a third species, considered in respect of figure, which they call *modus*.

HABITUDE is also used, in *Philosophy*, for what we popularly call *habit*; viz. a certain disposition, or aptitude, for the performing or suffering of certain things, contracted by reiterated acts of the same kind.

HACHES, and **HACHING**. See **HATCHING**.

HACK, a tool used by miners, in shape like a mattock.

HACKNEY. See **HACKNEY**.

HACKNEY COACH. See **HACKNEY COACH**.

HADDOLE, in our *Old Writers*, a recompence or ornaments for violence offered to persons in holy orders.

HADDOCK, the *gadus aeglefinus* of Linnaeus, in *Iceland*, a name given by us to a species of fish of the *AULACUS* kind, according to the generality of writers; but of the genus of the *CADU*, according to the new Artedean system. It is called by Salvian the *albus major*, or *crater albidus*, and by Turner and Willoughby, the *sea* or *sea* of the ancients. Chastell tells us, that it was the *calius*, *galus*, or *palus*, of the old Romans, mentioned by Pliny; but Artedi has some doubt about that. It is called by Artedi by a name much more expressive than any of the old ones. This is the *palus* with a bearded mouth, with three fins on the back, with a whitish body, with the upper jaw longest, and with the tail a little forked.

Large *adducts* begin to be in use in the middle of November, and continue to till the end of January; from that time till May they are very thin tailed, and much out of season. The small ones are extremely good from May to February; and those which are not old enough to breed in February, March, and April. The fishermen assert, that in rough weather *adducts* sink down into the sand and *crabs*, in the bottom of the sea, where they shelter themselves till the storm is over, because they take none in stormy weather. In summer they live on young herrings, and other small fish; and in winter on a species of *crabs*, called the *bone-coated worm*, and by fishermen *badlock-worm*. The grand feast of *adducts* comes periodically on the coast of Yorkshire, the large ones quit the shell as soon as they get out of season, leaving behind abundance of small ones, and are said to visit the coast of Hampshire and Ireland in the summer. On each side of the *badlock* there is a large black foot, streaked by saprophilous to the impression made by St. Peter's finger and thumb, when he took the tribute money out of the mouth of a species of this fish. Pennant.

HADSE, in *Mineralogy*, signifies any shaft or turn which descends like the side of a house, or like the descent of a steep hill. It is then said to *have*.

HADSE. See **ADSE**.

HADRIANA, or **HADRIANALIA**, in *Antiquity*, games instituted by Antonine, at *Pezusoli*, in honour of the emperor Hadrian, or Adrian.

There are two sorts of *Hadrianalia*, the one held every year, and the other every five years.

HADRIANISTS, *Hadrianists*, in *Church History*. See **ADRIANISTS**.

HÆMACHATES, the *Medicinal* *agate*, in the *Natural History of the Minerals*, the name of an *agate* found at this time in the East Indies, and in some parts of Germany, and called by Dr. Hill *adustus sanguineus carnegius*, or the blood-coloured variegated *agate*.

It is one of the most beautiful of the *agate* kind, and was extremely well characterised by the name the ancients gave it, being always of a strong and deep red like that of blood. Often it is only of this plain and single colour throughout the mass, but more frequently it is found beautifully variegated with a pale blue, and with brown; the blue in this case always surrounding the red, and appearing like the serum which separates from and flows about the blood, when it has been some time out of the body. The brown or hair-colour is often the base or ground colour of the stone, and the red in spots only, and variegations, surrounded with this thin blood colour; it is very hard, and takes a fine polish, and is cut into the tops of sword-handles, and other toys, and much valued by our lapidaries.

HÆMAGOGOS, of *algæ*, *kind*, and *algæ*, I show away, the name of a medicinal composition described in *Myrrhine*, and intended to bring away the lechia, or forward the menstrual discharges. It consists of black hellebore and the best gum, with honey.

HÆMALOIS, of *algæ*, *kind*, and *algæ*, a term used

by many authors for that blackness which appears about the eyes from blows; but *Hippocrates* uses it to express a black, thick, and faculent blood, overpreparing the cholor in the formation of the fetus, and rejected afterwards as of no use, and discharged into the space between the uterus and chorion. Some authors also use the word for spitting of blood.

HÆMANTHUS, in *History*. See **DIODORUS**.

HÆMATITES, from *algæ*, *kind*, in *Natural History*, the *blood-stone*, a kind of ruddy mineral substance; thus called, either on account of its resembling dry, curdled blood, or of its reputed faculty of staining blood. Pliny reckons five kinds of blood-stone; viz. the *Ethiopian*, *Arabian*, the *Arabian*, the *Arabian*, or *Arabian*, and the *Arabian*, besides that commonly called in his time the *magister hamuliter*, from the property it hath of attracting iron.

The five sorts differ chiefly in point of hardness; the best, according to Dioscorides, is that which is friable, hard, black, and smooth, without either gritty parts, or veins. That commonly used by the painters is fictitious, being made of Armenian bole, and other drugs.

The common native, or the fossil kind, comes from Egypt, Bohemia, &c. This is of various figures; spherical, semi-spherical, pyramidal, or cellular; composed of small pyramids, the apices of which appear, in a transverse section, in the centre. It contains a large portion of iron; but the iron is obtained with great difficulty, and is of so bad a quality, that this ore is not commonly smelted. This stone, when exposed to a moderately strong fire, falls by degrees into scales; and in this state is attracted by the magnet, and gives out its iron to acids. It has divers uses in medicine; being held cooling and astringent, and, in that quality, prescribed in hemorrhages and uterine obstructions. It is given in substance, in form of a fine powder, from one scruple to three or four, for a dose. It is also used in distemperatures of the eyes; but pure iron, or the preparations of iron, must be preferable to this stone in the same intention. The gilders use it for burnishers, to polish their metals.

Boschius has an expressive treatise on the *hæmatitis*.

HÆMATION, a word used, among the *Antiquaries*, for a sort of reddish giron, made of the intestines and blood of fishes macerated in salt.

HÆMATOCELE, of *algæ*, *kind*, and *algæ*, *tumor*, is a tumor of the testis, or of the spermatic process, occasioned by extravasated blood. This disease is distinguished by Mr. Pott into four kinds; two of which have their seat in the *testis vaginalis*; the third within the *algæ*; and the fourth in the *tunica communis* of the spermatic vessels. The two former happen in consequence of the operation of tapping the hydrocele of the *tunica vaginalis*; so that either by the division of a blood-vessel in the original coat, or by the bursting of some of the vessels after the operation, the cavity which had been filled with water, becomes in a very little time distended with blood; and must in both cases, if not absorbed or dissipated, be discharged by opening the containing bag; but in neither of these, says Mr. Pott, is cauterisation ever necessary; the mere division of the scrotum, and the application of dry lint to its inside, will in general restrain this kind of hemorrhage, and answer every purpose for which so severe as well as unnecessary a remedy has been prescribed.

The third kind happens, when the blood is extravasated within the *tunica albuginea*, in consequence of a great relaxation, and, as it were, dissolution of part of the valvular compages of that gland. In this case, the hemorrhage proceeds from the substance of the testicle, and from the convulsions of the spermatic artery within the *tunica albuginea*; the testicle itself is injured and rendered useless, and cauterisation is the only certain cure.

The last species of *hæmatocèle* consists of a rupture or breach of a branch of the spermatic vein, between the groin and scrotum, in the spermatic process, which may be occasioned by external violence and straining, as well as by a wound in this part. In this case, the extravasation is made into the cellular membrane, over the spermatic vessels; the hazard is sometimes considerable, and cauterisation often the only remedy. Pott's *Surgical Works*, vol. II. p. 382, &c. 1759. See **HYDROCELE**.

HÆMATOCHYSIS, of *algæ*, *kind*, and *algæ*, a term used by Willis, and some others, for a hemorrhage.

HÆMATOPUS, in *Ornithology*, a bird called by others the *rex marina*, or *sea-pige*. This, in the Linnaean system of nature, makes a distinct genus of birds of the order of the *grællæ*; the distinguishing characters of which are, that the feet are formed for running, the toes are three in number on each foot, and separate, and the apex of the bill, which is compressed, in form of a wedge.

HÆMATOPUS ardes, the red-legged heron, a very beautiful bird common in Italy, and called by the ancients *CRANUS*; it is one of the imitators of the heron kind, and is of a yellowish chestnut colour.

HÆMATOSIS, formed of *αἷμα*, blood, in *Medicina*, the action whereby the chyle is converted into blood: called also *SANGUIFICATION*.

The chief of the vital actions are the chylois, and hæmatosis.

HÆMATOXYLON, in *Batany*. See *LOCWOOD*.

HÆMIONUM, in *Batany*, a name by which Dioscorides calls the *opistimum*.

HÆMITYSION, in the *Writings of the Ancients*, a linen piece of apparel fringed on both sides. Others call it a sort of kind of handkerchief to wipe off sweat; but Galen makes it signify a thick piece of linen cloth. In this he has an eye to some passages of Hippocrates, where the word forms plainly to be used in that sense; others of the ancients have also used it exactly in the same meaning.

HÆMOCERCHINUS, of *αἷμα*, blood, and *κερχειν*, roughness of the throat, in *Medicina*, a vertigo, or faintness of the mind, arising from a spitting of blood, attended with a rattling noise in the nose and fauces.

HÆMODIA, a suppur of the teeth, caused by austere and acid substances.

HÆMOPHOS, in *Medicina*. See *HÆMOPHYTIS*.

HÆMOPHYTIS, formed of *αἷμα*, blood, and *φυτον*, to spit, corruptly also called *Hæmoptosis*, and *Hæmoptoe*, in *Medicina*, spitting of blood, occasioned by the rupture or erosion of some vessel of the lungs; and accompanied usually with a cough, and a sense of pressure on the breast.

The hæmoptoe differs from a vomiting of blood, in that in the hæmoptoe the blood comes from the lungs, and for that reason is florid and frothy; whereas in vomiting of blood, it comes from the stomach, and is blackish.

The hæmoptoe is either *accidental* or *habitual*. The latter is a symptom of the phthisis.

This disorder is by some confounded with the sputum cruentum, or bloody spit, but very improperly; since in this case the blood is thrown up pure and florid from the lungs, and without any violent efforts; whereas in the other the saliva is only thrown out tinged or streaked with blood, and that with much trouble and laborious hauking; and sometimes a slight erosion of the gums or fauces mixing the saliva with blood, will occasion the same appearance. The hæmoptoe differs also from the vomiturge of blood, in that the blood is arterial and unmixed, and voided without emotion, and with a little cough; whereas in the other case there is always a straining to vomit, and the blood is venal, and usually coagulated, and there is no cough.

Signs of it. The hæmoptoe is generally preceded by a sensation of oppression and narrowness of the breast; or more tacitly by a sort of itching or tickling felt all along the upper araxis; and in most cases there is a dry, and not very violent or troublesome cough, for some time before. Sometimes it is preceded by shivering, colic, costiveness of the excrements, colic, great lassitude, distension, pain of the back and limbs, &c. Sometimes however, the blood is voided without any of these antecedent symptoms, and only with a sensation of something warm coming up out of the breast to the mouth.

Persons subject to it. This is a case that more rarely happens than most other of the complaints of the lungs; and the persons afflicted with it are principally young men between eighteen and twenty-five; it very rarely happens after thirty, and principally affects persons of a plethoric habit, or such as use high-seasoned food. Persons of a slender make and lax fibres, who have long necks and breast breasts, are most liable to this disease. Women are more subject to it than men, from the frequent disturbances nature meets with in the menstrual discharges; and people who are accustomed to loud speaking or singing, are sometimes afflicted with it, from the violent distensions they give to the vessels of the breast. Sometimes also it takes persons who have changed an active life to a sedentary one; and more than any other, those who have had some other hæmorrhage, or natural and habitual evacuation, stopped upon them, without having the caution to bleed or evacuate properly on the occasion. Accordingly it has been a common observation, that those who have been subject to bleeding at the nose when young, are afterwards most liable to this disorder.

Causes of it. Youth and a plethoric habit, with too great a derivation of the blood upon the lungs, are sometimes the natural causes of this; but external accidents frequently concur, or of themselves bring it on: such are all violent straining of the breast; violent attempts to lift or carry burdens to which the body is not accustomed, blowing vehemently in the playing on trumpets and other wind instruments, excessive drinking, and violent passions, as

anger, &c. and violent motions in wrestling, running, jumping, or the like; violent coughing may also bring it on; but this is not the case so often as is supposed, the cough attending this disorder, and supposed to be the cause of it, being usually only a symptom of it.

This disease may also proceed from wounds of the lungs, and from a polypus, scirrhus, cancer, or any thing that obstructs the circulation of the blood in the lungs. It is sometimes occasioned by breathing too rare an air, as in the case of those who work in furnaces, glass-houses, &c. or of those who ascend very high mountains.

Prognosis from it. This is a disorder of the utmost consequence, and is by far the most dangerous of all hæmorrhages; and though the quantity of blood voided is seldom so great as to bring on sudden death, yet what remains extravasated in the lungs easily corrupts there, and brings on a phthisis, of which death is the consequence. The use of violent astringents is often the cause of this also, where nature would have escaped it. However, if the patient is strong, and of a sound constitution, the danger is not very great; but the disorder is with difficulty removed from persons of a delicate frame and lax fibres. If it proceeds from a polypus, or scirrhus of the lungs, it is alarming; and when the discharged blood is coagulated by an ulcer of the lungs, it is generally fatal. In some cases, as in pleuritis, peripneumonia, and many other fevers, it is not an unfavourable symptom; but in a dyspepsy, scurvy, or consumption, it indicates an ulceration of the lungs.

The method of cure. When the quantity of blood brought up is small, and the symptoms not violent, such things only are to be given as quiet the violent emotions of the blood; such are nitre and cinabar, made into powders with crab-eyes, or any other absorbent. If the case is more violent, a gentle anodyne or opiate may be added, such as the pill de *styrac*, or de *glyster*. In more violent cases, where the attenuating medicines take no effect, the milder astringents are to be used; or if the urgency of the symptoms make it necessary, even the stronger; such as the acid chair of vitriol, fifteen or twenty drops of which may be given in a glass of water, three or four times a day; but with these there should always be given a gentle opiate. Thus, ten or twelve drops of laudanum may be given in a cup of barley water, twice a day, and continued for some time, provided they be found beneficial; the antimonial crocus of steel, and the vitriolic colicthars, may then be given with the *styrac*-pill. Revulsion must also be attempted by diaphoretics, bleeding in the foot, and clysters, and gentle purges; and finally, the cure is to be completed by pectorals and detergents.

Dr. Dickson very much recommends, from his own experience, the use of nitre in this disorder: the mode in which he administers it is in the form of an electary, prepared of four ounces of conserve of red roses, and half an ounce of nitre; and he directs the quantity of a large tawney to be taken four, six, or eight times a day, according to the urgency of the case. This electary, he says, is almost as much to be depended upon, when given early in an hæmoptoe, as the *cortex Peruvianus* in a genuine intermittent. In private practice, the nitre joined with *hyperaceti*, or p. e. *trag*, has produced equally good effects. *Junker's Conf. Med.* p. 30. *London Med. Obs. vol. iv. p. 210.* *Buchan's Dom. Med.* p. 367. ed. 5.

When the pulse is hard and full, blood-letting should be occasionally repeated. Those who are subject to frequent returns of this distile, should avoid all excess; their diet should be light and cool, consisting chiefly of milk and vegetables; and every liquor that is used, should be drank cold. Above all, they should beware of vigorous efforts of the body, and violent agitations of the mind.

If a suppression of the menies, or hæmorrhoidal discharges, have been the cause of the distilement, great care is to be taken to bring them on regularly again, by bleeding in the foot, applying leeches to the hæmorrhoidal vessels, and the like means. Authors distinguish an hæmoptoe into a great many species, such as *angustifrons*, *diarrhæa*, *diapneumia*, *risis*, and *diaphoresis*; and write a great deal of the different causes of these hæmoptoes, and of the signs by which they are to be distinguished. But a late author thinks this of little importance. He thinks it most advantageous to consider a hæmoptoe simply as a preternatural efflux of blood, and as such it agrees with the hæmorrhage of the nose, vomiting of blood, dysentery, bloody urine, too great flow of the menies, &c. all which have the same immediate causes, the same effects and consequences, and suggest the same indications of cure; which are, in the beginning, to diminish the quantity of blood, and to make a revulsion by opening a vein in the arm, foot, &c. then to moderate the velocity and rarefaction

faction of the blood by cooling medicines; and lastly, to contract and strengthen the vessels by astringents. The same method must take place in all; and therefore the general style of the treatment of diseases ought to be hæmorrhagic. See Medic. Lib. Edin. vol. i. art. 25.

HÆMORRHAGE, compounded of *hæmo*, blood, and *rhago*, I burst forth, in *Hæmorrhæa*, a flux of blood at any part of the body arising either from a rupture of the vessels, as when they are too full, or too much pressed; or from an erosion of the same, as when the blood is too sharp and corrosive.

The hæmorrhages, properly speaking, as understood by the Greeks, was only a flux of blood at the nose; but the moderns extend the name to any kind of flux of blood, whether by the nose, mouth, lungs, stomach, intestines, hæmorrhoids, natrix, or whatever part.

Hæmorrhages are divided, by the medical writers, into natural and preternatural.

HÆMORRHAGIA, natural, comprehends bleeding at the nose, spitting of blood, the fluxes of the hæmorrhoids and menses, the lochia in *hæmorrhæa*, vomiting of blood, and voiding blood by urine.

HÆMORRHAGIA, preternatural, are such as derive their origin from external accidents, as falls, blows, and wounds. Some also comprehend, under this term, the artificial evacuations, by bleeding, cupping, and the like.

Hæmorrhages differ much, according to the age and state of the patient, and other accidents. Those from the nose are most frequent in young persons; those of the hæmorrhoids in people of a middle age, or later in life; the spitting of blood, to persons in a middle age; and voiding blood by urine usually to older people. Some hæmorrhages are periodical, which are the efforts of nature to relieve herself, and should by no means be obstructed, from whatever part of the body they proceed, unless they are very violent; and others vague or uncertain. The first observe some fixed periods of time for their return upon people; the last are wholly uncertain in that particular. Some are also termed critical; these are such as happen at the crisis of fevers. There are usually violent pains about the part whence natural hæmorrhages are to proceed; but these always go off as soon as the bleeding comes on in due quantity.

HÆMORRHAGES, persons most subject to. Young persons of a healthy and florid constitution are most subject to hæmorrhages; people of plethoric habits are also much subject to them, and especially such whose blood is found and fluxile, not subject to any dyscrasy. Those who drink much wine, or eat high-seasoned foods; and, more than all these, persons who are subject to violent passions, especially to anger. Hence it is, that brutes are very rarely afflicted with them.

Hæmorrhages, causes of. Among the principal of these are to be numbered a plethora, a laxity of the vessels, an inflammatory disposition of the blood, generally increased with some degree of fever, a distended state of the blood, as in neural diseases, the dysentery, the scurvy, the malignant small-pox, &c. or occasioned by the too liberal use of medicines which tend to dissolve it, as cathartics, the volatile alkaline salts, &c. violent commotions of the body, and violent passions of the mind, hot foods and liquors, strong purges and vomits, a heat of the season, and a sudden cooling of the body after violent heat and passion. *Junker's Consp. Med.* p. 11.

Preynotes from them. *Hæmorrhages* from the lungs, and vomiting, and voiding blood by urine, are all very dangerous. The others, when regulated, and in due proportion, are salutary, and often prevent diseases. And the common custom of stopping them by astringents, or otherwise, is often productive of stagnations, inflammations, and violent fevers.

Method of cure. *Hæmorrhages* flowing moderately, and from natural pulgæ, require no assistance of medicine; when they happen to plethoric persons, they are to be suffered to continue a sufficient time. When the quantity of the blood is lessened by these discharges, its quality, if diseased, is next to be amended by internal remedies; if superfluous and acid, by nitrous medicines and alkalis, and by gentle acids; to this purpose fat primæ, crab-apples, lemon-juice, and the like, are excellent; if the blood be too thick, a smaller quantity of food, and a larger of drink, it is to be preferred; and to this the relaxant and attenuating medicines are to be added, as the neutral salts and diuretic roots. These are the necessary things out of the fit; and during the bleeding such things are to be given as repeat the violent emotion of the blood, such as cinnamon, nutmeg, and crab-apples, fated with a vegetable acid. Spirit of hartshorn, and tincture of antimony, may next be given; and, after these, moderately styptic and astringent medicines; but the stronger styptics and astringents are not to be used but with great caution; because, by increasing the force of the circulation, they must be prejudicial.

The *styptic powder* of Helvetius has been found excellent in hæmorrhages.

The *vitrum antimonii cratum* has likewise proved very efficacious in *uterine hæmorrhages*.

The cure of a hæmorrhage must be adapted to its cause. When it proceeds from too much blood, or a tendency to inflammation, bleeding, with gentle purges, and other evacuations, will be necessary. It will likewise be proper for the patient in this case to live chiefly upon a vegetable diet, to avoid all strong liquors, and food that is of an acid, hot, or stimulating quality. The body should be kept cool, and the mind easy.

When a hæmorrhage is owing to a putrid or dissolved state of the blood, the patient ought to live chiefly upon acid fruits with milk, and vegetables of a nourishing nature, as *figs*, *galeps*, &c. His drink may be wine, diluted with water, and sharpened with the juice of lemon, vinegar, or spirits of vitriol. The best medicine in this case is the Ferrious bark, which may be taken according to the urgency of the symptoms.

When a flux of blood is the effect of acid food, or of overly stimulating medicines, the cure is to be effected by fat and mucilaginous diet. The patient may likewise ride frequently about the bulk of a marmoset, Locatelli's balsam, or the fine quantity of *spermaceti*.

When an obstructed perspiration, or a sticture upon any part of the system, is the cause of a hæmorrhage, it may be remedied by drinking warm oiling liquors, lying in bed, bathing the extremities in warm water, &c. *Burchar's Dom. Med.* p. 359, ed. 5.

Dr. Hunter observes, that the faintness which comes on after hæmorrhages, instead of alarming the by-standers, and making them support the patient by stimulating medicines, as *spiritus of hartshorn* and *cordials*, should be considered as salutary; as this seems to be the method which nature takes to give the blood time to coagulate. This observation has been confirmed by an experiment of the late ingenious Mr. Hewson, who found, that the disposition of the blood to coagulate is increased as the animal becomes weaker; and, therefore, the medicines likely to be service in stopping hæmorrhages, are such as cool the body, lessen the force of the circulation, and promote that languor or faintness. *Phil. Trans.* vol. ix. p. 404, &c.

His experiments also shew, that a vein may be opened with propriety, even where there is no plethora, in order suddenly to bring on weakness; by which the momentum of the blood may be so diminished, and the disposition of the lymph to coagulate may be so increased, as to stop the hæmorrhage.

Soft compression is, by *Garengeot*, thought more effectual to stop hæmorrhages than tight ligation, and his use recommended even when distichs of arteries give way, in which case the use of virrid button is criminal.

Hæmorrhages, internal. The omentum itself is not free from being the seat of fatal internal hæmorrhages, though this rarely happens. The *Petersburgh Commentaries* give us an account of a woman, who dying almost immediately after a blow received on the belly, was opened, and the cavity of the abdomen was found greatly distended with blood, which had plainly been out-largened from the omentum, as a great number of grumes of blood were found lodged between its foliages. It was observed also, in this subject, that the omentum was firmly attached to the fundus of the uterus.

The same paper give an account also of another very remarkable internal hæmorrhage; this was of the stomach. In this case the patient died instantaneously; and the blood having been discharged into the stomach too fast, either for its being ejected upwards or downwards, when the body was opened, the stomach was found greatly distended, and completely filled with one great grume or mass of coagulated blood. It is remarkable, that in this subject, the stomach was found in a perfectly sound state, but the spleen was found putrid and rotten. *Act. Petropol.* vol. i. p. 332.

Hæmorrhage, or bleeding of the nose, is usually preceded by some degree of quickness of the pulse, fullness in the face, pulsation of the temporal arteries, heaviness in the head, dimness of the sight, heat and itching of the nostrils, &c. This discharge is of considerable service in many disorders; it often cures a vertigo, the headache, a phreny, and even an epilepsy; it is very beneficial in fevers, inflammations of the liver and spleen, and often in the gout and rheumatism; in all cases where bleeding is necessary, a spontaneous discharge of blood is much more serviceable than the same quantity drawn away with a lancet. Whenever bleeding at the nose relieves any bad symptom, and does not proceed to far as to endanger the patient's life, it ought not to be stopped; but when it returns frequently, or continues till the pulse becomes low, the extremities begin to grow cold, the lips pale, or the patient complains of being sick or faint,

it must immediately be stopped: for this purpose the patient should be let nearly upright, with his head reclining a little, and his legs immersed in water of the warmth of new milk; his hands should likewise be put in lukewarm water; his garters may be tied a little tighter than usual; and ligatures applied to the arms, which should be gradually slackened as the blood begins to stop. If dry lint, put up the nostrils, does not stop the bleeding, doffils of lint, dipped in strong spirits of wine or brandy may be applied in the same manner: blue vitriol, dissolved in water, may also be used for this purpose, or a tent dipped in the white of an egg beat up, and rolled in a powder made of equal parts of white sugar, burnt alum, and white vitriol, may be put up the bleeding nostril. If the genitals be immersed for some time in cold water, the bleeding will almost always be stopped. The internal medicines proper in this case is Glauber's salt and manna, of each of which half an ounce, dissolved in four or five ounces of barley-water, may be taken for a dose, and repeated till it produces the effect. Ten or twelve grains of nitre may also be taken in a glass of cold water and vinegar, every hour, or oftener, if the stomach will bear it.

Mr. Le Dran proposes to make a seton, like that mentioned in the article *POLYPUS*, for stopping *hemorrhages* of the nose; for which purpose he fastens two doffils to the cord, and, after drawing one out at the nostril, to bring away the clotted blood, he continues to draw the cord, and so fills up the posterior part of the nostril with the other, which ought to be larger and well wet in a styptic liquor; by which, not only the *hemorrhage* will be stopped, but if it should continue, the blood and medicines will be effectually prevented from running down the throat, which commonly occasions a cough or vomiting that increases the bleeding. Those who are subject to bleeding at the nose should often bathe their feet in warm water, and keep them warm and dry; and their blood, if they have too much, may be lessened by a vegetable diet and an occasional cooling purge; but if the disorder proceeds from a thin dissolved state of the blood, the diet should be rich and nourishing. Infusions of the bark in wine ought likewise to be taken and perspired in for a considerable time. Med. Ess. Edin. vol. ii. p. 318. Buchan's Dom. Med. p. 361. 5th edit.

HÆMORRHAGES, unnatural, a term used by some medical writers to express such discharges of the blood as are made from parts not naturally, or in the common course of things, admitting such evacuations. Of these we have a very remarkable instance, recorded in the Philosophical Transactions: it is of a young child, which bled first at the nose and ears, and afterwards at the hinder part of the head, where there was no fore, and afterwards at the shoulders, waist, and at the fingers and toes, and the bending of the arms.

HÆMORRHAGES from wounds. Profusion of blood, from wounds, arises from injuries of the veins or arteries, received in the inflicting the wound; and the violence of the *hemorrhage* is ever in proportion to the size of the wounded vessel: it is no wonder, therefore, that great weakness, fainting fits, and sometimes instant death, are the dreadful consequences attending this symptom, according to the size of the wounded vessel. The surgeon ought, for this reason, never to be without the proper remedies to stop blood about him; but there are some cases in which it is by no means proper to stop the *hemorrhage* instantly. In a young plethoric habit, or in a wound got in a drunken fit, or even in a fit of great passion, it is best to let the blood run as long as it continues to do so without inconvenience to the patient; for, by a moderate loss of blood, the inflammation, tumor, pain, and fever, are either entirely prevented, or much lessened; besides, the divided arteries become more capable of contracting, and the blood more readily coagulates, two circumstances that seem to concur in closing the bleeding orifices.

The stopping of *hemorrhages* is to be done by various ways: if no large vessel is wounded, dry lint alone is always sufficient; the wound is to be filled with this, and a proper compress and bandage put over it. The wound must be filled pretty closely with the lint, and a proper degree of pressure given over the compresses with the hand, by which more is done sometimes than by all the bandages or violent remedies in the world. But if the *hemorrhage* is too large to be stopped by the application of dry lint alone, the use of astringent medicines is to be called in: the usual application, in this case, is rectified spirit of wine applied cold to the wound, filling it up with doffils dipped in the same spirit, and covering it with large compresses wrung out of the same liquor, and making a proper pressure over all with a bandage; the other astringents, used on this occasion, are vinegar,

the lycoperdon, or puff-ball oil, and spirit of turpentine; alum, vitriol, or saccharum saturni, dissolved in water and vinegar, or the dry powders of bole armeniac, blood-stone, dragon's blood, &c.

When vessels of a larger size are divided, we are to have recourse to caustic medicines instead of astringents, the common medicine, in this intention, is the Roman vitriol, which being coarsely powdered and sprinkled upon cotton, is to be applied to the wound, dressing up with doffils, a compress, and bandage. It is usually necessary to be very cautious in the application of this, that it only be laid to the bottom of the wound, or the part where the vessel wounded lies, otherwise the other parts will suffer too great an erosion from it.

If all these applications prove fruitless, it will be proper wholly to divide the artery, yet only divided in part; for, by this means alone, it will contract and hide its end under the muscular flesh, and its orifice will, by that means, either be entirely choked up, or at least it will be more ready to yield to the force of the medicines before advised to be used on such occasions. This method of treatment is most usually necessary in wounds of the temporal arteries, and those of the cubits and elbow.

If this method should fail, you must then have recourse to the hot iron or actual cautery; the orifices of vessels being burned, a crust is formed over them, and this method is so very effectual, that it is scarce possible for an *hemorrhage* to happen in wounds of the external parts, which may not certainly be stopped by it. In this case, two cauteries should be always ready, that, if one should be extinguished before the operation is finished, the other may be at hand without waiting for it. Cauteries are made of different shapes and sizes, according to the parts they are intended to be applied to. The great inconvenience attending the use of the cautery is, that, after two or three days, the eschar sometimes falls off, and then a second, and that commonly a fatal *hemorrhage* succeeds; to prevent this fatal accident, the wounds must be handled very tenderly at the time of dressing, and every time the wound is dressed, to be provided with a cautery ready heated, to repeat the operation if it should be necessary. This caution is to be observed, in regard to the larger arteries, for fourteen days; after this there is no great danger of a return of the complaint; but when the crural or axillary arteries are wounded, the cautery is of no use.

In very dangerous wounds of the large arteries, such as the crural and axillary, and in amputations of the limbs, the safest method is that of making a ligature round the vessels: if this is performed by passing a strong waxed thread under the artery, by means of a crooked needle, the blood is presently stopped, and the orifices of the artery coalesce.

Instruments for the stopping of *hemorrhages* have also been in use in all ages, which, by their forcible compression on the part, stop the mouths of the vessels, the most convenient of which is thus composed: a brass plate, three fingers long, and two fingers broad, is perforated in the middle to admit a strong screw, which is provided at the lower end with a small round plate; a piece of leather is strongly fastened to one end of the brass plate, of equal breadth with it. In violent *hemorrhages* this instrument is fitted to the wounded part. The end of the leather is brought round the part, and, by means of holes made through it, is fastened, at the proper part, to two small hooks made on the brass plate, at the end opposite to that where the leather is fastened; this is to be adjusted in such manner, that the small plate at the bottom of the screw is to be brought to press exactly upon the compresses and dressings that cover the wound; the handle of the screw is then to be turned round with a gentle pressure, till it is so far turned enough to make a pressure of force, to stop the blood: it is then to be left in this condition for a day or two, or till it may be safely taken off. Heister's Sur. p. 45.

Mr. Petit, in examining all the different methods employed by surgeons for stopping *hemorrhages*, assures us, that in each of them a piece of clotted blood is contained in the vessel, which serves to keep the blood from escaping, after the effect of the medicine, first employed, ceases: where absorbents or astringents are used, that there is not only a cylindrical piece of clotted blood in the vessel, but there is a covering of it on and round the orifice of the cut vessel, which cylindrical form makes it easily pushed out. Caustics have much the same effect, only the covering on the extremity of the vessel is firmer, by the solid parts being conformed with the clotted extravasation. When a ligature is used, there is no clotted covering, and the internal plug is of a pyramidal figure, therefore it is with difficulty that such a clotted piece can be pushed out. Besides this advantage, the sides of the vessel, which are brought to be contiguous by the liga-

ture, will probably grow together; for which reason, and the saving both pain to the patient, and loss of substance to the stump, he prefers compression to all the other methods. In proof of the effects of coagulated blood stopping the efflux of blood from large arteries, he relates two histories; in one the artery was ulcified, and in the other it lay in a bony groove: so that, in both, it must have been a plug which prevented the hæmorrhage. He endeavours to prove that the plug is stronger and firmer when formed of coagulated lymph than when composed of red blood. For excising the compression right, after amputation of the larger extremities, he has contrived a machine, composed of a large circular belt to be put round the trunk of the body, or superior part of the member, which are to sustain the bandage by straps going from it, which are fastened at the other end to a lesser circular belt; that is put round the part of the member where the tourniquet is commonly applied. This lesser belt is to have two screws, &c. in the form of his screw tourniquet. From this lesser belt four straps go out, to cross over two plates with their screws, as in the tourniquet, placed on the stump. When the operation is performed, he applies thick bolsters of lint on the side of each large artery farthest from the bone, and placing the inferior convex plate of the small tourniquet on them, he secures it in the right situation with the four straps, and screws down the plate on the bolsters and vessels, which being pressed between the instrument and the bone, can allow no blood to pass. See *Mém. de l'Acad. des Sciences*, 1731 and 1732.

Mr. Morand imagines, that the change which happens to the artery on being wounded, consists greatly in stopping the flux of blood, and that this and the congelation are usually joint agents in this case. When the artery is either copied, or at least less diffused than usual with blood, it naturally will collapse, in some degree, and become more or less flaccid; and if this goes so far as that the sides come to touch one another, they naturally unite, and the whole cure is performed by this alone; and this is very frequently the case in wounds of small arteries, and in internal hæmorrhages. Nor is it more difficult for a large vessel to become flattened and collapse in the same manner, till its sides touch, provided that the course of the blood through it be by any means restrained. Mr. Morand gave the Academy of Sciences of Paris a very remarkable account of a thing of this kind, which fell within his knowledge. A countryman having received a violent blow upon his arm, had afterwards no pulsation in the artery, in that part of the arm beneath the place where the blow had been given, though he had a pain one in that part of the artery which was above it. There was at first some fear that the arm must have been taken off, but Mr. Morand saved it, and, as the cure went on, the pulse was observed gradually to be felt again in the hand and lower part of the arm. The occasion of this was plainly, that the artery had become flattened by the blow; and the blood was unable to force the opposition, and circulated only through the small vessels, while the injury from the blow remained violent, but gradually made its way again as the parts reduced themselves to their natural state.

A wounded artery, in case it be cut quite asunder, is in the same state with a cord which is cut in two while it is on the stretch. We well know, that when this is done, the two ends recede a great way from one another, and that in proportion to the tension they had before: the case is wholly the same with an artery, and that for the same reason. Its longitudinal fibres are drawn back and shortened, and its circular ones are, by this very action, compelled to run together more close than they naturally float, and form thicker rings about the extremities of the divided vessel; the consequence of which is, that they make the inner hollow narrower. This is a thing of great importance, as not only the sides of the vessel are brought nearer together, and therefore they more easily may come to touch; but the diameter of the base of the artery being less, a smaller mass of coagulated blood than top it, and this blood adhering to the sides of the wound on every hand, fills up the passage as it congeals, and by degrees, brings the ends together. Mr. Petit, in confirmation of his opinion, that hæmorrhages are stopped by plugs of clotted blood, shewed the Academy of Sciences at Paris such a plug, in an artery which had been opened. See *Hist. de l'Acad. des Sciences*, 1735.

What is remarkable is, that this plug of clotted blood had lost nothing of its consistency, nor of its adhesion to the aperture of the artery, after lying two months in water, and three years in brandy. This shews the plug to be analogous to a fort: nor is this strange, since both are formed from the juices derived to the neighbourhood of the part. *Hist. de l'Acad. Par.* 1738.

A hæmorrhage at the anus is more usually called a *hemorrhoid*.

HÆMORRHOIDAL, an epithet given to the veins and arteries of the intestine rectum and the fundament, as being the seat of the hæmorrhoids or piles.

The hæmorrhoidal arteries are two; the one internal, the other external.

The internal is a branch of the lower mesenteric, which running along the rectum, terminates at the fundament. The external springs from the hypogastric artery.

The hæmorrhoidal veins are also internal and external.

The internal carries back the blood of the rectum and fundament, which it embraces regularly; and is inserted sometimes into the splenic branch of the porta, and sometimes into the mesenteric. The external brings back the blood from the muscular parts about the fundament, and terminates the hypogastric vein.

HÆMORRHOIDS, in Medicine, a disease of the fundament, popularly called the piles.

The word is formed of *haima*, sanguis, profluviu, flux of blood; which is compounded of *anus*, blood, and *sis*, I flow.

The hæmorrhoids are a painful, periodical tumor in the lower part of the intestine rectum; usually appearing external in the anus. They may be considered as a sort of various tumors in the hæmorrhoidal veins; arising from the too great abundance of morbid blood therein. The disease is either *simple*, as when the veins alone are tumefied; or *compound*, as when the neighbouring parts become also infected, or an excrescence arises therefrom, as a *ficus cristæ galli*, *condyloma*, or the like.

Hæmorrhoids again are either open, *punctate*, that is, when there is a discharge of blood from the hæmorrhoidal vessels, or blind, *cæca*, where the parts are only tumid, and there is no discharge: the former are vulgarly called the bleeding; and the latter the blind piles. In the first, the vessels of the rectum are open; in the latter, there is some obstruction, which occasions them to swell.

The hæmorrhoids sometimes are internal, and cause great pain in going to stool, especially if the feces be indurated; after which they soon appear externally, and blood is seen upon the excrements.

Emmeller is careful in distinguishing the genuine hæmorrhoidal flux from a bloody diarrhoea, frequent in scorbutic cases. The hæmorrhoids are usually opened by the attrition of the excrements in a stool, so that the blood flows at the same time with the excrements: but if it flows promiscuously before as well as after the excrements, and without pain, it is a scorbutic flux.

Hæmorrhoids are distinguished from the manner and time of their return upon the patient, into regular or periodical, which are a salutary discharge, and ought by no means to be stopped, and vague or irregular.

Hæmorrhoids, *prope*. They are generally preceded by a sensation of pain and tension in the *hypochondria*, and vibrative or spastic motions about the stomach, mesenteric, and spleen; and what is much more obvious than these, there is a sensation, as it were, of a hard nucleus sticking in the extremity of the rectum; and the more high up in that intestine this is felt, the more difficult will be the eruption of the hæmorrhoidal discharge, and the longer before its appearance. With these symptoms there also very frequently comes on a *tenesmus*: these are the usual antecedent signs, but there are some in whom they appear without any previous notice. When present, there is a discharge of blood, and that usually very pure and florid in persons who have them frequently and regularly: in others who have them seldom and imperfectly, the blood appears black and grumous, and in some cases especially in persons who never had a genuine and proper flux of this kind, there is excreted a sanious matter instead of pure blood. The evacuation of the blood from this is seldom voluntary, but usually is forced out by the pressure and hardiness of the stools.

Hæmorrhoids, *per se* subject to them. They equally affect both sexes, but are oftener met with in men than in women, especially those who are of a sanguine plethoric habit, or of a melancholy disposition, or in those who live high, and lead a sedentary inactive life. They are most frequent in the middle and advanced ages of life, and when they happen to young people they are usually hereditary.

Hæmorrhoids, *causes of them*. Among these are to be reckoned a plethora, and thickness of the blood, for an extreme thinness and acrimony of it are seldom the cause, though very often supposed to be so. Violent convulsions of the abdomen, as by violent exercises of riding or walking, will also bring them on, as will a sedentary life, in which, by the compression of the abdomen, the circulation is impeded at the vena portæ: also an omission of

of any customary evacuations of blood, great coliciveness, cold in the parts affected by them, an abuse of hot foods and spirituous liquors, and the taking of aloe, or other like medicines. In Saxony the hemorrhoids are very frequent, from their taking great quantities of elixir proprietatis; and in Hungary, from their eating large quantities of garlic: violent binding of the bowels, and passions of the mind, especially anger and fear, and the venereal infection, will also frequently bring them on; but this last cause chiefly brings on the blind piles, or such as do not bleed.

HEMORRHOIDS, prognostics from them. The hemorrhoids, when they flow naturally and moderately, are very beneficial to health, and often prevent violent diseases. They are peculiarly the most certain of all remedies in the hypochondriacal affections; they ease deliriums, and very often are peculiarly beneficial in the gout, rheumatism, album, colic, and inflammatory fevers. With all these advantages derived from them, when moderate, they are, however, attended when immediate, or when too long continued, with bad symptoms, and are often dangerous: they bring on great weakness, and in length of time, induce cachectic dispositions; but they very seldom are attended with so copious a hemorrhage as to endanger life on the sudden, though this has sometimes happened. The sudden stopping them is always dangerous, and often brings on immediate fatal symptoms, scirrhus of the viscera, inflammations, melancholy, madnes, vomiting of blood, and dropsies; and jaundices are often the consequence of such practice. Those persons who have them while very young, generally are attended regularly with them through their lives, and seldom live to be very old; on the contrary, when they do not appear till persons are advanced in years, and continue regular and moderate afterwards, they promise a long life. Finally, when the hemorrhoids are continual, and flow without any intermissions, there is great cause to suspect a scirrhus or ulcerated state of some of the abdominal viscera.

HEMORRHOIDS, method of treatment. When the hemorrhoids have never yet appeared, but there are signs of their approaching, it is not always advisable to forward or promote their discharges, for they seldom answer exactly to expectation; but when there is room to fear the success, it is better to endeavour at a revulsion by bleeding in the arm or foot, and at the same time to strengthen the tone of the parts by a decoction of yarrow, or the like medicines; and the bleeding is to be repeated afterwards at stated periods, and the use of the internal means continued, if necessary; but when the hemorrhoids have already been used to flow, as soon as the patient feels the signals of their approach, their discharge is always to be gently promoted, by a moderate use of elixir proprietatis or tincture of black hellebore, or its resin made with spirit of wine; and externally by the application of leeches, or, if that is not sufficient, by opening the veins with a lancet. Junker's Conf. Med. p. 47.
